The treatment of cases of acute lead poisoning consists in the administration of alkaline carbonates, soap, soluble sulphates, sodium chloride, or other antidote, and in washing out the stomach with large draughts of water, the exhibition of castor oil or other non-irritating laxative if it be thought advisable to clean out the intestines, and the employment of opium, counter-irritation, and the other means habitually used against toxic gastro-enteritis. In the treatment of subacute and chronic lead poisoning the efforts are to be directed first to combating the symptoms, secondly to aiding in the entire elimination of the lead. George B. Wood was accustomed to consider alum as almost a specific remedy for the relief of painter's colic, in which disease it is also essential to employ opium for the relief of pain, and laxatives to overcome the constipation; with these latter should always be given extract of belladonna in full dose, to aid in the relaxation of the intestinal spasm. Magnesium sulphate is probably the best purgative. In chronic lead poisoning the paralysis is to be combated by hygienic means, massage, and electricity, precisely as when it arises from other causes. H. C. Wood has seen in that form of lead poisoning which resembles poliomyelitis the immediate arrest of progressive symptoms by the use of doses of strychnine continually increased until the evidences of physiological action were obtained. For the purpose of eliminating lead from the system potassium iodide should be administered continuously for weeks and months in such doses as the stomach will bear. Warm sulphur baths are also useful.¹ Lead has been found in almost all the tissues of the body in fatal cases of poisoning.

In moderate dose, or in not too concentrated solution or amount, the soluble preparations

rent is kept up from one to six hours, according to the quantity of lead in the solution. A dark-gray or black deposit on the electrode in the urine indicates the probable presence of lead. The electrode upon which the deposition occurs is taken out of the urine without interrupting the electrical current, and washed by gently dipping it several times in distilled water. The foil is then placed in a small beaker, covered with nitric acid, and, after warming five or ten minutes on a water bath, taken out, washed with distilled water, and the wash water collected in the beaker containing the nitric acid. The nitric acid solution is evaporated to dryness, and the residue dissolved with a few drops of dilute potassium hydroxide solution, and then slightly acidulated with acetic acid. The solution thus prepared is tested for lead by the well known reagents, hydrogen sulphide, potassium iodide, or diluted sulphuric acid.

¹ Warm sulphuretted baths may be provided by dissolving four ounces of potassium sulphide in thirty gallons of water, in a wooden tub. These baths cause discoloration of the skin, from the formation of lead sulphide, and should be repeated every few days, until this effect ceases to be produced. After each bath the patient should be well washed with soap and water with the aid of a flesh brush, in order to remove the discoloration. By proceeding in this way, the lead on the skin, or in its pores, is rendered insoluble and inert, and at the same time removed.

of lead act as sedative astringents. When locally applied they contract relaxed vessels or tissues. When taken internally they check secretion in the alimentary canal,—according to the views of the older therapeutists, reducing the action of the heart and of the arteries, and restraining secretions generally. The insoluble preparations of lead differ therapeutically from the soluble preparations, in being free from irritant properties and acting only as feeble astringent sedatives. The preparations of lead are at present chiefly used as local applications.

Orfila has determined, by experiments on dogs, the appearance exhibited by the mucous membrane of the stomach after the use of small doses of the salts of lead. After the action of such doses for two hours, dull white points are visible on the membrane, sometimes in rows and sometimes disseminated, and evidently consisting of the metal, united with the organic tissue. If the animal be allowed to live for four days, the same spots may be seen with a microscope; and if hydrogen sulphide be applied to the surface, they are instantly blackened. (*A. G. M.*, 3e sér., iv. 244.)

PODOPHYLLUM. U. S. (Br.)

PODOPHYLLUM [May-Apple, Mandrake Root]

(pôd-ô-phÿl'lüm)

"The dried rhizome of *Podophyllum peltatum* Linné (Fam. *Berberidaceæ*)."
U. S. "The dried rhizome and roots of *Podophyllum peltatum*, Linn." Br.

Podophylli Rhizoma, Br.: *Podophyllum* Root, Wild Mandrake, Devil's Apple, Umbrella Plant, Vegetable Calamel; Rhizome de *Podophyllum*, Fr. *Cod.*; Fussblattwurzel, G.; *Podofillo*, It.; *Podofilo* (Rhizoma de), Sp.

For *Podophylli Indica Rhizoma Br. Add.* and its preparations see PART II.

Podophyllum peltatum, L., *Sp. Pl.* (1753) 505; *Willd., Sp. Plant.* ii. 1141; Barton, *Med. Bot.* ii. 9; Carson, *Illust. of Med. Bot.*, i. 18, pl. 11; B. & T. 17.—The may-apple, sometimes also called *mandrake*, is an indigenous herbaceous plant. The rhizome is perennial, creeping, usually several feet in length, about one-quarter of an inch thick, brown externally, smooth, jointed, and furnished with roots at the joints. The stem is about a foot high, erect, round, smooth. The basal leaves are centrally peltate, with six or seven wedge-shaped lobes, irregularly incised at the extremity, yellowish green on their upper surface, paler and slightly pubescent beneath. The flower-bearing stems bear from one to three similar leaves. The flower is nodding, and appears between two leaves at the apex of the stem or at the base of the upper leaf when three leaves are present. The calyx is composed of three oval, obtuse, concave, deciduous sepals. The corolla has from six to nine white, fragrant petals, which are obovate, obtuse, concave, with delicate transparent veins. The sta-

mens are from thirteen to twenty, shorter than the petals, with oblong, yellow anthers, of twice the length of the filaments. The stigma is sessile, and rendered irregular on its surface by numerous folds or convolutions. The fruit is a large oval berry, crowned with the persistent stigma, and containing a sweetish fleshy pulp, in which about twelve ovate seeds are embedded. It is, when ripe, of a lemon-yellow color, diversified by round brownish spots. Two species of the genus *Podophyllum* are known as growing in China while *Podophyllum Emodi*, which inhabits the interior ranges of the Himalayas and is very abundant in Cashmere, is recognized in the Br. Add. (See PART II.)

The plant has been found on Mount Togakushi, in Japan, and is extensively diffused through the United States, growing luxuriantly in moist shady woods and in low marshy grounds. It is propagated by its creeping rhizome, and is often found in large patches. The flowers appear about the end of May and the beginning of June, and the fruit ripens in the latter part of September. The leaves are said to be poisonous. The fruit has a subacid, sweetish, peculiar taste, agreeable to some palates, and may be eaten freely with impunity. From its color and shape, it is sometimes called *wild lemon*. The rhizome is the official portion, and is said to be most efficient when collected after the falling of the leaves. It shrinks considerably in drying. For a paper by Smyth Ely Jelliffe on the histology of the powdered rhizome see *D. C.*, 1899, 196.

Properties.—The dried rhizome is much wrinkled lengthwise, is yellowish or reddish brown externally, and furnished with fibres of a similar but somewhat paler color. It was determined, by an experiment of Wm. Saunders, that these fibres contain as much active matter as the rhizome itself. The fracture is short and irregular, and the internal color whitish. The microscopic examination of the section shows the rhizome to be composed of loose parenchymatous tissue, with sixteen or more yellowish vascular bundles arranged in a circle, and a cortical layer of a double row of thick-walled yellowish cells surmounted by the epidermis. It is officially described as “of horizontal growth and variable length, subcylindrical, flattened above, sometimes branched, consisting of joints 5 to 10 Cm. long, the internodes 2 to 8 Mm. thick; externally pale yellowish-brown to dark brown, nearly smooth; nodes annulate, the upper surface being marked by large cup-shaped scars, the lower surface with numerous root-scars or remains of roots; fracture short, the fractured surface mealy or horny, whitish to pale brown, with a circle of small wood-bundles, and a large pith; odor slight, more pronounced and characteristic in the powder; taste sweetish and disagreeably bitter and acrid.” *U. S.* The powder is light yellowish gray, resembling that of jalap. The root in its aggregate state is nearly inodorous, but in powder has a sweetish not unpleasant

odor. The taste is at first sweetish, afterwards bitter, nauseous, and slightly acrid. Both the decoction and the tincture are bitter, but alcohol is said to be the best solvent of the active matter. V. Podwysotszki (*Ph. Z. R.*, Bd. xx. 777) announced the active principle to be solely a neutral crystalline principle, *picropodophyllin*. This principle is associated with an inactive resin-acid, *picropodophyllic acid*, and the combination of the two he named *podophyllotoxin*. *Picropodophyllin* is in colorless, silky, extremely delicate needles, very soluble in chloroform, readily soluble in 95 per cent. alcohol, but very slightly in 75 per cent. alcohol. It is soluble in ether, and crystallizes from a warm saturated solution on cooling. It is insoluble in water, turpentine, or benzin. *Podophyllotoxin* is a bitter, white, resinous powder, soluble in weak alcohol and hot water. It may be precipitated from its alcoholic solution by water in large quantity. (*P. J.*, 1882, 1011.) Podwysotszki also obtained *podophylloquercetin*, the coloring principle, which is closely allied to quercetin and is the cause of the varying color of resin of *podophyllum*. His results have since been corrected and supplemented by R. Kürsten (*A. J. P.*, 1891, 485), who has obtained the several principles in a purer state. The results of Kürsten's investigation are as follows. The *podophyllotoxin* prepared by Podwysotszki's method was not constant in composition, and its melting point varied from 100° to 125° C.; further, the *podophyllic acid* of that author is composed mainly of a crystallizable, active, but very impure substance.

Podophyllotoxin, $C_{28}H_{42}O_8$, is obtained by extracting the coarsely powdered rhizome with cold, light petroleum, until freed from fat; after drying in the air, the extraction is continued with chloroform, until the liquid comes away almost free from yellow color. As it is not possible to work with alcohol-free chloroform, too prolonged extraction with chloroform would yield a more impure extract. The chloroform extract is distilled and the residue is dried over a not too warm water bath, partially dissolved in benzene, filtered, and the filtrate allowed to remain from three to eight days, when a brownish-yellow mass of well-formed, thick, strongly refractive prisms is produced, which is purified by washing with a 50 per cent. alcohol, then with ether, recrystallizing first from boiling benzene, and finally from solution in hot 45 per cent. alcohol; the compound is thus obtained in long, well-formed prisms.

Podophyllotoxin, when oxidized in an alkaline solution in the cold by means of potassium permanganate, yielded, besides a little carbonic anhydride and a brown amorphous substance, principally two compounds, the more considerable of which was *podophyllic acid*, obtained as well-formed, colorless crystals from solution in a mixture of benzene and alcohol. The compound is without action on

animals. It melts at from 158° to 160° C. Its aqueous solution, neutralized with aqueous potassium hydroxide, gives no precipitate with gold, calcium, or barium chlorides; silver nitrate gives a white precipitate, soluble in much water; copper acetate gives a blue precipitate. The copper salt was prepared as beautiful light green prisms and analyzed.

Pieropodophyllin results from the action of alkalis on podophyllotoxin; thus, on heating the latter with aqueous ammonia, a well-crystallized product is obtained, which at first was recrystallized from strong alcohol; but this was found to be unnecessary, as the melting point, 227° C., was not affected by it. *Pieropodophyllin* has the same composition as podophyllotoxin, but they differ in melting point and in their action on polarized light,—the former inactive, the latter lævo-rotatory; the former is less soluble in all liquids than the latter; the latter gives Millon's reaction, the former does not. By oxidation and reduction the two compounds yield the same products.

Dunstan and Henry (*Proc. Chem. Soc.*, March, 1898) find that the constituents of the Indian podophyllum (*Podophyllum Emodi*) and of the American podophyllum (*Podophyllum peltatum*) are identical. The chief constituent is the *podophyllotoxin* of Podwysotszki and Kürsten, which is a neutral substance possessing, according to Kürsten the formula $C_{20}H_{15}O_6(OCH_3)_3 + 2H_2O$ and crystallizing in prisms melting at 94° C. It is strongly lævo-rotatory, and acts as a powerful purgative and intestinal irritant. When heated with alkalis, it is converted by hydration into the salt of an unstable gelatinous acid, *podophyllie acid*, $C_{15}H_{11}O_7$, of which several salts were obtained and analyzed. This acid very readily loses water, and furnishes the crystalline *pieropodophyllin* of Podwysotszki and Kürsten, which is isomeric with podophyllotoxin. It passes again into podophyllie acid when warmed with aqueous alkalis. It melts at 227° C., and is optically inactive. Podophyllotoxin and pieropodophyllin furnish identical decomposition products; when oxidized with nitric acid, oxalic acid is the principal product; when fused with alkalis, *orcinol* and acetic acid are produced. Both substances contain three methyl groups and no hydroxyl. It is likely that pieropodophyllin is the lactone of podophyllie acid. *Pieropodophyllin* is therapeutically inactive. The yellow coloring matter of podophyllum, called by Podwysotszki *podophylloquercetin*, is proved by the authors to be identical with quercetin, the yellow coloring matter of quercitron bark. An uncrystallizable resin, *podophylloresin*, was also isolated and found to exert a purgative action. A fatty oil has been separated from the rhizome of podophyllum by Dohme and Engelhardt. (See *Proc. A. Ph. A.*, 1904, 340.) Gordin and Merrell (*Proc. A. Ph. A.*, 1902, 343) propose to judge of the quality of resin of podophyllum by an assay based on the percentage of crude pieropodophyllin and

the following requirements. 1. Pure podophyllin must be completely soluble in about twice its weight of cold alcohol. 2. It should contain about 64 per cent. ether-soluble and about 74 per cent. chloroform-soluble matter. 3. It should yield about 22 per cent. crude pieropodophyllin when assayed by the method described by them.

Manlius Smith recommended that the resin should be prepared by forming an alcoholic tincture of the root, evaporating the tincture until most of the alcohol is driven off, and throwing the residue into water, by which the resin is precipitated. The concentration should not be carried too far, as otherwise the resin separates in clots, which cannot be easily washed. According to Smith, the resin, when pure, is white, and purges actively. It has been called *podophyllin* for many years. (*A. J. P.*, xxiv. 306. See *Resina Podophylli*.) The proportion of resin contained in the root of the *P. peltatum* appears to vary very much, the variation possibly depending upon the season of the year at which the drug has been gathered. John Barclay (*P. J.*, 1903, Feb. 164) obtained a percentage of 1.6 to 3.86 per cent. stating that these figures were confirmed by the results of the manufacturers of podophyllin on a large scale, but J. C. Umney states that in five years experience working with batches of 1000 lbs. the rhizome averaged a yield of 6.6 per cent. Both observers noticed that the Indian rhizome (*P. Emodi*) contains a much larger proportion of resin, the average according to Umney being 11.4 per cent. How far the proportion of podophyllotoxin varies in the different rhizomes does not seem to have been determined. (See B. D. Dott, *P. J.*, 1903, Mar. 460.)

From the leaves of *P. peltatum* Thos. J. Husband, Jr., obtained berberine and a resin which was free from purgative properties, 8 grains producing no other effect than slight headache. (*A. J. P.*, 1869.)

B. F. Carter (*A. J. P.*, 1886, p. 449) also examined the leaves. He found tannin, uncrystallized sugar, coloring matter, and 6 per cent. of resin. This latter seems to be of two-fold character, ether dissolving the soft resin, while the hard resin remains behind. The resin has a bitter taste and a much milder action than that of the rhizome. Fused with potassium hydroxide a small amount of protocatechuic acid seems to be formed.

Uses.—Podophyllum is a slow but active and certain cathartic, producing copious liquid discharges, often with much griping. It is generally thought by the profession to be an efficient cholagogue and the experiments of Rutherford upon dogs aid in confirming this belief. It is much employed in various parts of the country in *bilious fevers* and *hepatic congestions*, and as a general cathartic. In minute doses, frequently repeated, podophyllum has been thought to diminish the frequency of the pulse and to relieve cough, and

for these effects has been given in *hæmoptysis* and *catarrh*, but this employment of it is of doubtful advantage. In overdoses podophyllum acts as an irritant poison; an amount estimated at five grains of the resin caused death in a woman sixty years old (N. Y. M. R., April, 1890); the symptoms were vomiting and purging, followed some hours after their cessation by coma, full soft pulse, slight elevation of temperature, and hæmoglobinuria.

The powdered root is rarely administered, although the U. S. P. gives the dose as $7\frac{1}{2}$ grains (0.5 Gm.); the official resin is much used, under the improper name of *podophyllin*.

Dose, of the resin, from one-eighth to one-quarter grain (0.008 to 0.016 Gm.); as a purgative, from one-quarter to one-half grain (0.016 to 0.032 Gm.).

POTASSA SULPHURATA. Br.

SULPHURATED POTASSA [Liver of Sulphur]

(pō-tās'sa sūl-phū-rā'ta)

"A mixture of salts of potassium, of which the chief are potassium sulphides." Br.

Hepar Sulphuris; Potassil Sulphuretum, U. S. 1870; Sulphuret of Potassium, Sulphurated Potash; Sulfure (tri) de Potassium solide, Fr. Cod.; Sulfure de Potasse, Fole de Soufre, Fr.; Kalium Sulfuratum, P. G.; Schwefelleber, Kallschwefelleber, G.; Sulfuro (tri) potassico hiposulfitado, Sp.

This preparation is not official in the U. S. P. (8th Rev.). The U. S. P. 1890 process for its production is as follows: "Sublimed Sulphur, *one hundred grammes* [or 3 ounces av., 231 grains]; Potassium Carbonate, dried, *two hundred grammes* [or 7 ounces av., 24 grains]. Mix the powdered and dried Potassium Carbonate thoroughly with the Sublimed Sulphur, and gradually heat the mixture, in a covered crucible, which should be only about half filled with it, until the mass ceases to foam and is in a state of perfect fusion. Then pour the fused mass on a cold marble slab, and, after it has cooled, break it into pieces, and keep it in a well-stoppered bottle." U. S. 1890.

"Potassium Carbonate, in powder, *10 ounces* (Imperial) or 100 grammes; Sublimed Sulphur, *5 ounces* (Imp.) or 50 grammes. Mix the Potassium Carbonate, previously dried, and the Sulphur, in a warm mortar; introduce them into a crucible; heat this, at first gradually, until effervescence has ceased, and finally to dull redness, so as to produce perfect fusion; pour out the liquid contents of the crucible on a clean flagstone, and cover quickly with an inverted porcelain basin so as to prevent free access of air while solidification is taking place. The solid product thus obtained should, when cool, be broken into fragments, and immediately enclosed in a green glass bottle furnished with an air-tight stopper." Br.

These processes are essentially the same, except that a greater heat is used in the British process, which somewhat modifies the result. When potassium carbonate is melted with half its weight of sulphur, as in the U. S. P. 1890 process, the carbon dioxide is expelled. The composition varies with the heat employed. If the heat does not exceed 185° C. (365° F.), the resulting preparation will contain potassium thiosulphate; if above 300° C. (572° F.), potassium sulphate. (Fordos and Gélis.) The reaction for the preparation at the lower temperature is

which at the higher temperature is changed as follows:

The potassium pentasulphide formed is decomposed at this high temperature into sulphur, which burns off, and K_2S_8 . The U. S. preparation, therefore, which is made at the temperature of fusion, probably contains potassium thiosulphate, and may be represented by the formula $2\text{K}_2\text{S}_3 + \text{K}_2\text{S}_2\text{O}_3$, three molecules of CO_2 escaping, while the British, being prepared at a red heat, contains potassium sulphate, the reaction probably being

Potassium carbonate from pearlsh is usually employed by the manufacturer, but in the process of Henry, which is stated to be the best yet devised, the pure potassium carbonate is employed. His formula is as follows. Mix two parts of pure potassium carbonate with one of sulphur reduced to powder, and put the mixture into flat-bottomed flasks, which should be only two-thirds filled. These are placed on a sand bath, and the fire is applied so as, at first, to produce only a gentle heat, which is afterwards increased. Care must be taken that the necks of the flasks do not become obstructed. The heat is continued until the matter is brought to a state of tranquil fusion, when it is allowed to cool. The mass obtained, which is compact, smooth, and of a fine yellow color, is broken into pieces, and preserved in well-stoppered bottles. W. Elborne (Y. B. P., 1896, 331) states that when commercial potassium carbonate is used in making sulphurated potassa, a product is obtained which more closely approaches the official compound (Br. Pharm. 1885) than does one made from a pure potassium carbonate. He recommends that dried commercial carbonate containing not less than 90 per cent. K_2CO_3 be employed.

Properties.—Sulphurated potassa, when properly prepared, is a hard, brittle substance, having a nauseous, alkaline, and bitter taste. Its color is liver-brown, and hence its name of *hepar sulphuris*, or *liver of sulphur*. The color of the surface of a fresh fracture is brownish-yellow. It is inodorous when dry, but emits a slightly fetid odor when moist, owing to the extrication of a little hydrogen sulphide gas. It is soluble in water, forming

an orange-yellow liquid, and exhaling the odor of hydrogen sulphide. It was officially described in the U. S. P. 1890 as follows: "When freshly prepared, Sulphurated Potassa forms irregular pieces of a liver-brown color, which, by exposure to the air, gradually absorb moisture, oxygen, and carbon dioxide, and change to a greenish-yellow and finally to a gray mass containing potassium carbonate, hyposulphite, and sulphate. The compound has a faint odor of hydrogen sulphide, and a bitter, alkaline taste. Soluble in 2 parts of water at 15° C. (59° F.), with the exception of a small residue. Alcohol dissolves only the potassium sulphide, leaving the other constituents (hyposulphite and sulphate) undissolved. The aqueous solution (1 in 10) is of an orange-yellow color, is strongly alkaline to litmus paper, and gives off the odor of hydrogen sulphide. On adding to it acetic acid in slight excess, an abundance of hydrogen sulphide is evolved, while sulphur is precipitated. In this liquid, after filtration, sodium bitartrate test-solution produces an abundant, white, crystalline precipitate. On triturating 1 Gm. of Sulphurated Potassa with 1 Gm. of crystallized copper sulphate and 10 Cc. of water, and filtering, the filtrate should remain unaffected by hydrogen sulphide test-solution, corresponding to at least 12.85 per cent. of sulphur combined with potassium to form sulphide." U. S. 1890. "Solid greenish fragments, liver-brown when recently broken, alkaline and acrid to the taste, readily forming with water a yellow solution which has the odor of hydrogen sulphide, and evolves it freely when excess of hydrochloric acid is dropped into it, sulphur being at the same time deposited. This acid liquid when boiled and filtered gives a yellow precipitate with solution of platinum chloride, and a white precipitate with solution of barium chloride." Br. By exposure to the air it attracts oxygen, and the potassium sulphide is gradually changed into potassium sulphate, when the preparation becomes inodorous, and white on the surface. The solution is decomposed by the mineral acids, which extricate hydrogen sulphide and precipitate the excess of sulphur. It is also incompatible with solutions of most of the metals, which are precipitated as sulphides. When boiled with an excess of hydrochloric acid and filtered, it gives a yellow precipitate with platinum chloride, and a white one with barium chloride. The preparation of the Br. Pharmacopœia yields about one-half of its weight to alcohol (90 per cent.),—the portion dissolved being potassium sulphide, and the undissolved portion potassium sulphate.

Uses.—Sulphurated potassa is a local irritant, and, in small and repeated doses, is said to increase the frequency of the pulse, heat of the skin, and different secretions, especially the mucous. Occasionally it causes vomiting and purging. It acts, moreover, as an antacid, and produces the alterative effects of sulphur. By some it is maintained to be sedative, and di-

rectly to reduce the action of the heart. It probably does so, when taken in considerable quantities, by the development of hydrogen sulphide. In overdoses it acts, according to Orfila, as a violent poison, corroding the stomach, and depressing the powers of the nervous system. Lead acetate or zinc acetate may be used as an antidote, but the latter is preferable, as less likely to act injuriously in an overdose, and having, besides, emetic properties. The diseases in which it has been most advantageously employed are *chronic rheumatism* and *gout*, and various *cutaneous affections*. It has been given also in *painter's colic*, *asthma*, and *chronic catarrh*, and acquired a short-lived reputation as a remedy in *croup*, after the publication of the essay to which the prize offered by Napoleon for the best dissertation on that disease was awarded. In consequence of forming insoluble sulphides with the metallic salts, it has been proposed as an antidote for some mineral poisons, but Orfila has shown that it does not prevent their effects. Dissolved in water, it has proved efficacious as an external application in *cutaneous diseases*, and in *scabies* is an almost certain remedy. It may be used for this purpose in the form of lotion, bath, or ointment. For a lotion it may be dissolved in water in the proportion of from fifteen to thirty grains to the fluidounce (1 to 2 Gm. to 30 Cc.), and for a bath the same quantity or rather more may be added to a gallon of water. A very small proportion of hydrochloric or sulphuric acid may in either case be added to the solution. The ointment is made by mixing half a drachm of the sulphide with an ounce of lard. The odor is very favorably modified, whether in solution or in the state of ointment, by incorporating with it a little oil of anise.

Dose, of sulphurated potassa, from two to ten grains (0.13 to 0.65 Gm.), repeated several times a day, and given in pill with licorice, or in solution with syrup. In *infantile croup*, from one to four grains (0.065 to 0.26 Gm.) were given every three or four hours.

POTASSII ACETAS. U. S., Br.

POTASSIUM ACETATE

(pō-tās'sī-i ā-cē'tās)

"It should contain, when thoroughly dried, not less than 98 percent. of pure Potassium Acetate [CH_3COOK], and should be kept in well-stoppered bottles." U. S. "Potassium Acetate, CH_3COOK , is prepared by fusing the product of the interaction of acetic acid and potassium carbonate." Br.

Kali Aceticum, Sal Diureticum, Acetas Potassicus, s. Kalicus, Terra Foiliata Tartari; Acetate of Potassium; Acetate of Potash (Potassa), Diuretic Salt; Acétate de Potasse sec, Fr. *Od.*; Essigsäures Kali, G.; Acetato di potassio, It.; Acetato potassico, Sp.

The substitution in the U. S. Pharmacopœia of 1870¹ of potassium bicarbonate for the carbonate used in the British formula was an improvement, as it insured a purer product. The form of acid for generating the salt is official acetic acid, and a colorless solution is obtained. This is evaporated to dryness, but the Br. Pharm. 1885 directed the dry salt to be melted, so that it could be obtained as a solid mass on cooling. When fusion is resorted to, great care must be taken not to use too high a temperature as otherwise part of the acetic acid will be decomposed, and the resulting salt will be discolored. For drying the potassium acetate, Christison considers the temperature of a vapor bath too low, and that of a sand bath likely to become too high. He therefore recommends the use of a bath of calcium chloride when operating on a small scale. In conducting the evaporation, it is best to have the solution always slightly acid, for if the alkali predominate, it will react upon the acetic acid when the solution is concentrated, and give rise to discoloration. On account of the liability to discoloration, great care must be observed to avoid the contamination of iron. Some manufacturers use silver dishes.

Potassium acetate may also be obtained by double decomposition between lead acetate and potassium sulphate. When thus procured, it is very white and pure, but liable to the objection, for medicinal use, that it may possibly contain a little lead. Another method by double decomposition is between calcium acetate and potassium sulphate.

Properties.—It is officially described as “a white powder, or in crystalline masses of a satin-like lustre, odorless, and having a warming, saline taste. Very deliquescent on exposure to the air. Soluble in 0.4 part of water, and in 2 parts of alcohol at 25° C. (77° F.); with increasing temperature it becomes much more soluble in both liquids. When heated to 292° C. (557.6° F.) the salt fuses. At a higher temperature it decomposes, blackens, and evolves vapors having an empyreumatic odor (an alliaceous odor would indicate the presence of *arsenic*), and finally, if ignited on platinum, it leaves a white residue, which should be completely soluble in water. The aqueous solution (1 in 20) is alkaline to red litmus paper, but does not affect phenolphthalein T.S. The addition of sodium bitartrate T.S. to the concentrated aqueous solution of the salt causes a white, crystalline precipitate. If a few particles of the salt be added to a mixture of 1 Cc. of sulphuric acid and 1 Cc. of alcohol, acetic ether will be formed, recognizable by its odor. The addition of a little ferric chloride T.S. to a solution of the salt

produces a deep red color, and, upon boiling, a pale brown, flocculent precipitate of basic ferric acetate separates.” U. S. “Either in white foliaceous satiny masses, or in granular particles, very deliquescent, alkaline to *litmus*, soluble in half its weight of *water*, and in 2 parts of *alcohol* (90 per cent.)” Br. When unskillfully prepared, it is apt to be more or less colored. Its state of aggregation differs according to the manner in which it is procured. As obtained by evaporating the solution to dryness, agreeably to the directions of the U. S. Pharmacopœia of 1870, it is in the form of soft fibrous masses. As usually prepared and found in commerce, it has a foliated texture, which is given to it by fusion and cooling. On account of this appearance, it was formerly called *foliated earth of tartar*. It must always be preserved in well-stoppered bottles.

Tests.—The most usual impurities contained in it are silica, potassium sulphate, tartrate, and chloride, and the lead and copper salts. “The aqueous solution of the salt (1 in 20), slightly acidulated with acetic acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). Five Cc. of an aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzzeit's Test for *arsenic* (see PART III, Test No. 17). If 1 Gm. of dry Potassium Acetate be thoroughly carbonized at a temperature not exceeding red heat, and the residue extracted with boiling distilled water until the washings cease to react with methyl-orange T.S., the mixed filtrate and washings should require for complete neutralization not less than 20.1 Cc. of half-normal sulphuric acid V.S., methyl-orange T.S. being used as indicator.” U. S. Since the introduction of the cheap method of obtaining pure acetic acid from wood, this salt has scarcely been subjected to adulteration. Potassium acetate is incompatible with the mineral acids, which expel the acetic acid; with sodium and magnesium sulphates; with corrosive sublimate and silver nitrate, and with several other earthy and metallic salts. This salt exists in the juices of many plants, and especially in the sap of trees, and is the principal source of the potassium carbonate existing in the ashes of wood. It consists of one atom of potassium combined with one acetic acid group, $\text{C}_2\text{H}_3\text{O}_2$.

Uses.—In doses of from twenty grains to a drachm (1.3 to 3.9 Gm.) potassium acetate acts as a diuretic, and as a mild cathartic when given to the extent of three or four drachms (11.25 to 15 Gm.). It is employed in *dropsies*, but is not so useful as the bitartrate. J. A. Easton of Glasgow, has found it useful in several skin diseases, such as *psoriasis*, *eczema*, and *lepra*, in doses of half a drachm (2 Gm.) three times a day. The alkaline treatment of *acute rheumatism* which originated with Golding Bird is very well carried out by this salt, half an ounce to an ounce (15 to 30 Gm.), in dilute solution, being given during the twenty-four hours. Potassium acetate, like the other alkali-

¹ “Take of Acetic Acid a pint; Bicarbonate of Potassium a sufficient quantity. Add the Bicarbonate gradually to the Acid until it is neutralized; then filter the solution, and evaporate cautiously, by means of a sand-bath, until a dry salt remains.” U. S. 1870.

line salts containing a vegetable acid, may be given in the *uric acid diathesis*, to render the urine alkaline, for the experiments of Wöhler and others have shown that the acid of these salts undergoes decomposition in the system, leaving the alkali free to act as a carbonate. Vegetable potassium salts increase the oxidation of tissue, and may therefore be very useful as depuratives.

Dose, half a drachm to half an ounce (2 to 15.5 Gm.).

POTASSII BICARBONAS. U. S., Br.

POTASSIUM BICARBONATE

(pō-tās'sī-lī bī-cār'bō-nās)

$\text{KHCO}_3 = 99.41$

"It should contain not less than 99 percent. of pure Potassium Bicarbonate [$\text{CO}(\text{OH})$] (OK)], and should be kept in well-stoppered bottles." U. S. "Potassium Bicarbonate, KHCO_3 , may be obtained by saturating a strong aqueous solution of potassium carbonate with carbonic anhydride." Br.

Bicarbonas Potassicus, s. Kallcus; Potassium Hydrogen Carbonate; Acid Carbonate of Potassium; Bicarbonate of Potash; Carbonate (bi) de Potasse, *Fr. Cod.*; Bicarbonate de Potasse, *Fr.*; Kallium Bicarbonicum, *P. G.*; Kallumbicarbonat, *Doppel-Kohlensaures Kali, G.*; Bicarbonato di potassio, *It.*; Bicarbonato potassico, *Sp.*

The process of the U. S. P. 1870,¹ and also that of the British Pharmacopœia, for this salt were abandoned at former revisions.

Brande gives the following proportions for the preparation of potassium bicarbonate: "100 lbs. of purified potassium carbonate are dissolved in 17 gallons of water [Imperial measure], which, when saturated with carbonic acid, yield from 35 to 40 lbs. of crystallized bicarbonate; 50 lbs. of potassium carbonate are then added to the mother-liquor, with a sufficient quantity of water to make up 17 gallons, and the operation repeated." Wöhler states that charcoal, when mixed with the carbonate, facilitates by its porosity, in a remarkable degree, the formation of the bicarbonate. Thus, he found that, when crude tartar was charred in a covered crucible, and the carbonaceous mass, after having been slightly moistened with water, was subjected to a stream of carbon dioxide, the gas was absorbed with great rapidity, and heated the mass so considerably as to render it necessary to surround the vessel with cold water, to prevent the decomposition of the bicarbonate formed. When the temperature diminished, the saturation was known to be completed. The mass was lixiviated in the smallest quantity of

water at the temperature of from 29.4° to 37.7° C. (85° to 100° F.), and the solution, after filtration and cooling, deposited the greater part of the bicarbonate in fine crystals. (See *A. J. P.*, x. 82.)

Behrens has proposed to obtain potassium bicarbonate by partially saturating the carbonate, dissolved in an equal weight of water, with acetic acid gradually added. Up to a certain point, no carbon dioxide is extricated, and a precipitate takes place of pure potassium bicarbonate, equal to half the weight of the carbonate employed. After the bicarbonate is separated, the saturation may be completed, and potassium acetate obtained. (*J. P. C.*, 3e sér., iv. 464.) L. Pesci dissolves purified potassium hydroxide in 80 per cent. alcohol, and passes a stream of carbon dioxide through the solution until it is saturated. The white precipitate is collected and washed with alcohol; it is free from chlorides and nitrates. (*Ber. d. Chem. Ges.*, 1876.)

According to Berzelius, the cheapest method of obtaining potassium bicarbonate is to suspend a concentrated solution of the purified carbonate, contained in a stoneware dish, within a cask, over a liquid undergoing the vinous fermentation. The alkali is thus surrounded by an atmosphere of carbon dioxide, and, by absorbing it, crystallizes into bicarbonate in the course of five or six weeks. Distillers and brewers may prepare this salt with great facility by suspending the alkaline solution in the fermenting tun. The salt in powder called *potash sal aëratum*, made principally in New England, is prepared in this way. In composition it is between a carbonate and a bicarbonate.

Properties.—Potassium bicarbonate is officially described as in "colorless, transparent, monoclinic prisms, or a colorless, odorless, granular powder, having a saline and slightly alkaline taste. Permanent in the air. Soluble in about 3 parts of water at 25° C. (77° F.), and in 1.9 parts at 50° C. (122° F.). At a higher temperature the solution rapidly loses carbon dioxide, and, after being boiled, contains only potassium carbonate. Almost insoluble in alcohol. The dry salt begins to lose carbon dioxide at 100° C. (212° F.), and this loss increases at a higher temperature, until, at a red heat, the salt has lost 30.96 percent. of its original weight, leaving a residue of carbonate. The concentrated aqueous solution of the salt is slightly alkaline to litmus paper, but neutral to phenolphthalein T.S. Tartaric acid T.S., added in excess to the concentrated aqueous solution, produces a white, crystalline precipitate. If 1 Gm. of the salt be dissolved without agitation in 20 Cc. of water at a temperature not above 15° C. (59° F.), and 0.2 Cc. of normal hydrochloric acid V.S. and 2 drops of phenolphthalein T.S. be added, a red tint should not appear immediately (limit of carbonate). The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for heavy metals

¹ "Take of Carbonate of Potassium *forty-eight troy ounces*; Distilled Water *ten pints*. Dissolve the Carbonate of Potassium in the Distilled Water, and pass Carbonic Acid through the solution till it is fully saturated. Then filter the liquid, and evaporate that crystals may form, taking care that the heat does not exceed 160°. Lastly, pour off the supernatant liquid, and dry the crystals upon bibulous paper. Carbonic acid may be obtained from marble by the addition of dilute sulphuric acid." U. S. 1870.

(see PART III, Test No. 121). To neutralize 1 Gm. of Potassium Bicarbonate not less than 19.9 Cc. of half-normal sulphuric acid V.S. should be required, methyl-orange T.S. being used as indicator." *U. S.* "Colorless monoclinic prisms, not deliquescent, of a saline feebly alkaline taste. It is soluble in 4 parts of cold water, but almost insoluble in alcohol (90 per cent.). It affords the reactions characteristic of potassium and of bicarbonates. Each gramme exposed to a low red heat leaves 0.69 gramme of a white residue, which requires for exact neutralization 10 cubic centimetres of the volumetric solution of sulphuric acid. It should yield no characteristic reaction with the tests for lead, copper, arsenium, aluminium, calcium, magnesium, sodium, nitrates, sulphates, or sulphides, and only the slightest reactions with the tests for iron or for chlorides. 20 parts by weight of Potassium Bicarbonate are neutralized by 14 parts of Citric Acid, and by 15 parts of Tartaric Acid." *Br.* When heated to redness it loses carbon dioxide and returns to the state of carbonate, which, when thus obtained, is free from silica, and otherwise very pure. This method was adopted in the *U. S. Pharmacopœia* of 1870 for obtaining the pure carbonate. When a perfect bicarbonate, its solution, unless heated, does not precipitate a solution of magnesium sulphate. This negative indication, however, cannot be depended upon as showing the absence of carbonate; for, according to Christison, no precipitate will be occasioned even when 50 per cent. of this impurity is present. Potassium bicarbonate does not decompose calomel. When dissolved in 40 parts of water, it produces a white haze merely with a solution of corrosive sublimate; but if it contain so much as a hundredth part of carbonate, a brick-red precipitate is immediately produced. (Christison.) Another way of detecting the presence of carbonate is to add pure glucose to a heated solution of the suspected bicarbonate. If any carbonate be present, the mixture will turn yellow or brown. (Chevallier.) The official test (Hirsch's) given above is, however, more reliable, and admits but traces of carbonate. Potassium bicarbonate consists of one atom of potassium and one of hydrogen, in combination with one carbonic acid group, CO_3 .

Uses.—The medicinal properties of this salt are similar to those of the carbonate, to which it is preferable from its milder taste and its greater acceptability to the stomach. It is, however, much more disagreeable than the salts of potassium made from the fruit acids which are now universally used when a decided effect upon the system is desired, the bicarbonate and the carbonate being employed almost exclusively as antacids.

Dose, ten grains to a drachm (0.65 to 3.9 Gm.).

POTASSII BITARTRAS. U. S. (Br.)

POTASSIUM BITARTRATE [Cream of Tartar]

(po-tās'si-i bi-tār'trās)

$\text{KHC}_4\text{H}_4\text{O}_6 = 186.78$

"It should contain not less than 99 percent. of pure Potassium Bitartrate [$\text{C}_2\text{H}_2(\text{OH})_2(\text{COOH})$] (COOK), and should be kept in well-stoppered bottles." *U. S.* "Acid Potassium Tartrate, $(\text{CHOH})_2\text{COOH.COOK}$, is obtained from the crude cream of tartar which is deposited during the fermentation of grape juice, and from the lees of wine." *Br.*

Potassii Tartaras Acidus, Br. Acid Potassium Tartrate, Crystals of Tartar; Tartrate de Potasse acide, Bitartrate de Potasse, Crème de Tartre, *Fr. Cod.*; Pierre de Vin, *Fr.*; Tartaras depuratus, *P. G.*; Weinstein, *Kall.* Bitartricum, Bitartras Potassicus, *s. Kallcus*, Cremor Tartari, *G.*; Tartrato acido di potassio, Cremor di tartaro, *It.*; Tartrato (bi) potassico, Cremor de tartaro, *Sp.*

During the fermentation of wines, especially those that are tart, a peculiar matter is deposited in the casks, forming a crystalline crust, called *crude tartar*, or *argol*. That deposited from red wines is of a reddish color, and called *red tartar*, while that derived from white wines is of a dirty-white color, and denominated *white tartar*. Both kinds consist of potassium, united with an excess of tartaric acid, forming acid potassium tartrate, rendered impure by calcium tartrate, more or less coloring matter, and other substances which are deposited during the clarification of the wine. The deposition of the tartar is thus explained. The acid tartrate exists naturally in the juice of the grape, held in solution by saccharine matter. When the juice is submitted to fermentation in the process for converting it into wine, the sugar disappears, and is gradually replaced by alcohol, in which the salt is insoluble. It is from argol that acid potassium tartrate is obtained by a process of purification. The importation of crude tartar, or argol, for the year 1903 was 29,966,557 lbs., valued at \$2,734,027; for 1904, 24,571,730 lbs., valued at \$2,550,223; and for 1905, 26,249,954 lbs., valued at \$2,289,331. Although the amount of crude tartar produced in the United States is small, compared with the quantity imported from Europe, yet the amount from American wines is rapidly increasing. The process for purifying crude tartar is founded upon the greater solubility of acid potassium tartrate in hot than in cold water. The tartar, previously pulverized, is boiled with water in copper boilers. The solution, when saturated, is transferred to earthen pans, where it deposits on cooling a crystalline layer, nearly free from color. This is redissolved in boiling water, and the solution, having been mixed with 4 or 5 per cent. of pipe clay,¹ is evaporated to a pellicle. The clay precipitates with the coloring matter, and the clear solution, as it cools, deposits white

¹ Egg albumin and animal charcoal are also employed for clarifying and decolorizing solution of crude tartar.

crystals in crusts, which, upon being exposed to the air on linen for several days, acquire an increased degree of whiteness. These constitute the *crystals of tartar* of pharmacy. The salt, as met with in commerce, is generally, for greater convenience, in the form of powder, to which the name *cream of tartar* properly belongs. (See *Bull. Pharm.*, 1898, 405.) Wittstein proposes to free cream of tartar from lime by diluted hydrochloric acid, which dissolves the lime preferably, and, if not used in excess, will take up very little of the potassium salt.

Properties.—Potassium bitartrate occurs in commerce in white crystalline crusts or masses of aggregated crystals, which are usually powdered before being sold to pharmacists. It is officially described as in "colorless or slightly opaque, rhombic crystals, or a white, somewhat gritty powder, odorless, and having a pleasant, acidulous taste. Permanent in the air. Soluble in about 200 parts of water at 25° C. (77° F.), and in 16.7 parts of boiling water; very sparingly soluble in alcohol. When a small portion of the salt is heated on platinum foil, it chars and emits inflammable vapors having the odor of burning sugar. At a higher temperature, with free access of air, the carbon of the black residue is oxidized, and a white, fused mass remains, which has an alkaline reaction and effervesces strongly with acids. The aqueous solution of the salt has an acid reaction upon blue litmus paper. With sodium cobaltic nitrite T.S. the aqueous solution of the salt yields a copious yellow precipitate. In the aqueous solution of the salt, rendered neutral by potassium hydroxide T.S. silver nitrate T.S. produces a white precipitate, which, on boiling, becomes black through the separation of metallic silver. If, before applying heat, just sufficient ammonia water be added to dissolve the white precipitate, and the solution boiled, a mirror will be deposited on the sides of the test-tube." *U. S.* "A gritty white powder, or fragments of cakes crystallized on one surface, with an acid taste. Soluble in 200 parts of cold water, insoluble in alcohol. It affords the reactions characteristic of potassium and of tartrates. Each gramme of the dry salt should require for neutralization at least 5.2 cubic centimetres of the *volumetric solution of sodium hydroxide*. It should yield no characteristic reaction with the tests for lead, copper, or iron, and only the slightest reactions with the tests for calcium, magnesium, sodium, chlorides, or sulphates. The total amount of impurities should not exceed 2½ per cent. of the dried salt." *Br.* With salifiable bases which form soluble tartrates, it gives rise to double salts, consisting of neutral potassium tartrate, and the tartrate of the base added. Several of these are important medicines. Cream of tartar, though sparingly soluble in water, becomes abundantly so by the addition of borax or boric acid.¹ (See *Sodii Boras*.)

Tests.—"A solution of 0.5 Gm. of the salt in 3 Cc. of ammonia water should leave no insoluble residue (absence of *starch, kaolin, calcium phosphate*, and other *insoluble matter*). The aqueous solution of the salt, slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). The odor of *ammonia* should not be evolved on heating the salt with a slight excess of potassium hydroxide T.S. If 1 Gm. of Potassium Bitartrate be well triturated with about 1 Gm. of potassium carbonate and 0.5 Gm. of potassium nitrate, and the mixture heated gradually to dull redness in a porcelain crucible, and, if, upon cooling, the resulting mass be treated with a slight excess of diluted hydrochloric acid and filtered, the filtrate, upon being made slightly alkaline with potassium hydroxide T.S., should not yield a gelatinous precipitate soluble in excess of the reagent (absence of *alum*). If a precipitate be produced which is insoluble, it should be collected and thoroughly washed with hot distilled water and dissolved in hot diluted nitric acid; the addition of an excess of ammonium molybdate T.S. to this solution should not produce a yellow precipitate (absence of *phosphates*). If 1 Gm. of Potassium Bitartrate be thoroughly carbonized at a temperature not exceeding red heat, and the residue extracted with boiling distilled water until the washings cease to react with methyl-orange T.S., the mixed filtrate and washings should require for complete neutralization not less than 10.6 Cc. of half-normal sulphuric acid V.S., methyl-orange T.S. being used as indicator." *U. S.*

The cream of tartar of commerce is now nearly pure potassium bitartrate. It has been, however, found purposely mixed with various substances, such as sand, clay, gypsum, flour, chalk, alum, and potassium sulphate. Sand, clay, and gypsum may be detected by their insolubility in a hot solution of potassium hydroxide; flour, by its striking a blue color with iodine; chalk, by its effervescing with dilute acids; alum (an unlikely sophistication), by its astringency, and any soluble sulphate, by its causing a precipitate with barium chloride, not entirely soluble in nitric acid. The action of the last-mentioned test is explained by the fact that the barium tartrate is soluble and the sulphate insoluble in nitric acid. The best security against fraud is to purchase the crystals and have them powdered. Geo. F. Payne examined commercial cream of tartar; of ten samples obtained from grocery stores, five contained no cream of tartar whatever. Some of the spurious samples were mainly composed of a mixture of dried alum and acid calcium phosphate. (*Proc. A. Ph. A.*, 1897, 695.) The *U. S. Pharmacopeia* (8th Rev.) admits a slight impurity. It should contain 99 per cent. of pure potassium bitartrate, and there is no difficulty

¹ Soluble Tartar. *Tartarus borazatus*, s. *Kali tartaricum borazatum*, s. *Cremor tartari solubilis*. Borax, 2 parts; distilled water, 20 parts. Dissolve,

and add 5 parts purified cream of tartar. Agitate to dissolve, filter, evaporate to dryness, and powder.

in obtaining it in commerce of this quality. Coupland gives in *P. J.*, 1901, 282, the results of an examination of commercial cream of tartar as follows: While in 1884 the assays of cream of tartar revealed from 8 to 14 per cent. of calcium tartrate, and in 1885 from 7 to 10.5 per cent., the larger percentages being found in the smaller crystals, the average from 1886 to 1890 was 6.5 per cent.; 1891 to 1894, 5.5 per cent.; 1895 to 1897, 3.0 per cent.; 1898, 5.0 per cent.; and 1899 to February, 1901, 4.6 per cent. But cream of tartar of greater purity is by no means an exceptional article, potassium bitartrate of a quality of 98 and 99 per cent. being common, the latter coming from America. The competition among makers of "baking powders," into which it enters, explains in part the improvement in the quality of cream of tartar.

Composition.—Cream of tartar consists of one molecule of tartaric acid, $C_4H_4O_6.H_2$, in which one of the two hydrogen atoms has been replaced by an atom of potassium.

Uses.—Potassium bitartrate is a very mild saline cathartic, and an active, soothing, hydragogue diuretic. In small doses it acts as a cooling aperient and in large ones as a hydragogue cathartic, producing copious watery stools. It is much used in *dropsy*. It is frequently prescribed in combination with senna, sulphur, or jalap. (See *Confectio Sulphuris* and *Pulvis Jalapæ Compositus*.) Its solution in boiling water, sweetened with sugar and allowed to cool, forms an acid, not unpleasant, refrigerant drink, advantageously used in some *febrile affections*, and frequently employed as a domestic remedy. The beverage called *imperial* (*potus imperialis*) is a drink of this kind, made by dissolving half an ounce of the salt in three pints of boiling water, and adding to the solution four ounces of white sugar and half an ounce of fresh lemon peel. *Cream of tartar whey* is prepared by adding about two drachms of the bitartrate to a pint of milk. It may be given in dropsical diseases.

As a diuretic, cream of tartar may be administered in the dose of a drachm and a half or two drachms (5.8 to 7.7 Gm.) several times a day. It is believed to escape from the system unchanged, and hence is not available when an alkaline influence upon the blood or renal secretion is desired. In pharmacy, cream of tartar is employed to obtain the neutral potassium tartrate (soluble tartar), potassium and sodium tartrate (Rochelle salt), antimony and potassium tartrate (tartar emetic), and iron and potassium tartrate (tartarized iron). Deflagrated with potassium nitrate, or incinerated alone, it is converted into a pure form of potassium carbonate, called salt of tartar. In the laboratory it is used to procure potassium hydroxide in a pure state, and for making black and white flux. *Black flux* is prepared by deflagrating cream of tartar with half its weight of potassium nitrate, and *white flux*, by deflagrating it with twice its weight of the same salt.

Dose, aperient, one to two drachms (3.9 to 7.7 Gm.); cathartic, half an ounce to one ounce (15.5 to 31 Gm.).

POTASSII BROMIDUM. U. S., Br.

POTASSIUM BROMIDE

(pō-tās'si-i brō'mī-dūm)

KBr = 118.22

"It should contain not less than 97 percent. of pure Potassium Bromide, and should be kept in well-stoppered bottles." *U. S.* "Potassium Bromide, KBr, may be obtained by adding a slight excess of bromine to a strong solution of potassium hydroxide, evaporating the solution of potassium bromide and bromate to dryness, decomposing the bromate by fusing the mixture with charcoal, and purifying by crystallization." *Br.*

Bromide of Potassium; Bromuretum Potassium, s. Kallcum; Bromure de Potassium, *Fr. Cod.*; Kallium bromatum, *P. G.*; Bromkallium, Kalliumbromid, *G.*; Bromuro di potassio, *It.*; Bromuro potassico, *Sp.*

In the first step of the *U. S.* process of 1870¹ a solution of ferrous bromide was formed, and this, by the addition of the solution of potassium carbonate, was decomposed so as to produce ferrous carbonate, which precipitated, and potassium bromide, which remained in solution. By straining, the precipitated carbonate was separated, and from the strained liquor potassium bromide was obtained by due evaporation. In the *Br. Pharm.* 1885, by reaction between potassium hydroxide and bromine, the potassium bromide and bromate are produced in solution, and, having been obtained dry by evaporation, are exposed with the powder of charcoal to a red heat, whereby the potassium bromate is converted into potassium bromide by the separation of its oxygen. The remainder of the process consists in obtaining the bromide in crystals by solution in boiling water, which deposits it on cooling.

Properties.—Potassium bromide is in "colorless, or white, cubical crystals, or a granular powder; odorless, and having a strongly saline taste. Permanent in the air. Soluble in about 15 parts of water, and in about 180 parts of

¹ "Take of Bromine two troyounces; Iron, in the form of Filings, a troyounce; Pure Carbonate of Potassium two troyounces and sixty grains; Distilled Water four pints. Add the Iron, and afterwards the Bromine, to a pint and a half of the Distilled Water, stirring the mixture frequently with a glass rod for half an hour. Apply a gentle heat, and, when the liquid assumes a greenish color, add gradually the Pure Carbonate of Potassium, previously dissolved in a pint and a half of the Distilled Water, until it ceases to produce a precipitate. Continue the heat for half an hour, and then filter. Wash the precipitate with the remainder of the Distilled Water, boiling hot, and again filter. Mix the filtered liquids, and evaporate that crystals may form. Lastly, pour off the mother-water, and, having dried the crystals on bibulous paper, keep them in a well-stoppered bottle." *U. S.* 1870.

alcohol at 25° C. (77° F.); in less than 1 part of boiling water, and in 16 parts of boiling alcohol; also soluble in glycerin. On heating the salt upon platinum foil it decrepitates; and at a temperature near 700° C. (1292° F.) it fuses without decomposing, and at a bright red heat volatilizes, communicating a violet color to the flame. Its aqueous solution (1 in 20) is neutral, or has only a scarcely perceptible alkaline reaction upon litmus paper. The addition of tartaric acid T.S., or of sodium bitartrate T.S., to a concentrated aqueous solution of the salt produces a white crystalline precipitate. Silver nitrate T.S. produces a yellowish-white precipitate, insoluble in nitric acid and in a moderate excess of ammonia water." *U. S.* "Soluble in 2 parts of cold water, and in 200 parts of alcohol (90 per cent.). It affords the reactions characteristic of potassium and of bromides. Each gramme, dissolved in water, requires for complete precipitation not less than 83.7 nor more than 85.4 cubic centimetres of the volumetric solution of silver nitrate. It should yield no characteristic reaction with the tests for lead, copper, arsenium, iron, aluminium, zinc, calcium, magnesium, sodium, ammonium, bromates, iodates, or cyanides, and only the slightest reactions with the tests for chlorides, iodides, or sulphates. *Test-solution of ferric chloride* should not cause a red coloration in the cold aqueous solution (absence of thiocyanates)." *Br.* According to Chas. D. Chase, the commercial salt often is decidedly alkaline, and will precipitate the alkaloïds from the solution of their salts; a serious mishap from such cause is very conceivable.

Tests.—To determine the percentage of chloride in an impure bromide the process of Baudrimont, as improved by Falières, may be used. It is founded upon the fact that chlorides precipitate more silver than the bromides, because of the lower atomic weight of chlorine as compared with bromine; for an explanation see *P. J.*, 1872, p. 542. Prepare a titrated solution of 0.852 gramme of silver nitrate in 100 cubic centimeters of distilled water. It is necessary, by means of ferric chloride, salts of barium, and strong sulphuric acid in excess, to insure that there are present no other salts, such as potassium iodide, carbonate, or sulphate, or sodium nitrate, which shall interfere with the results. Then dissolve one gramme of the bromide in thirty or forty grammes of water in a stoppered bottle, and add 1.427 grammes of silver nitrate in solution. When the precipitate has subsided, add, drop by drop, from a Gay-Lussac burette the titrated solution. If the bromide be pure, no precipitate forms; otherwise the number of cubic centimeters required to completely precipitate it equals the percentage of the chloride. An iodide of alkaline metal may be detected by adding to the solution of the bromide, palladium chloride, which will precipitate all the iodine in the form of palladium iodide, while the bromide of that metal will remain in solu-

tion. (*Ibid.*) According to Bobieure and Herbelin, potassium bromide containing iodide may be purified by boiling with bromine water and evaporating, the liberated iodine and the excess of bromine being driven off during the evaporation. (*J. P. C.*, 4e sér., x. 166.) The U. S. Pharmacopœia permits the presence of 3 per cent. of chloride in potassium bromide but insists on the absence of iodide and bromate. "If 1 Gm. of Potassium Bromide be dissolved in 10 Ce. of water and 0.1 Ce. of tenth-normal sulphuric acid V.S. be added, no color should be produced by the subsequent addition of a drop of phenolphthalein T.S., even after heating (limit of *alkali*). If diluted sulphuric acid be dropped upon crushed crystals of the salt, and the mixture be shaken with 1 Ce. of chloroform, the latter should not assume a yellowish-brown color (absence of *bromate*). If to 10 Ce. of the aqueous solution of the salt (1 in 20), 1 Ce. of chloroform be added, and if chlorine water, which has been diluted with an equal volume of water, be introduced cautiously drop by drop with constant agitation, the liberated bromine will dissolve in the chloroform, imparting to it a yellow to orange color, free from any violet tint (absence of *iodides*). The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). Ten Ce. of the aqueous solution of the salt (1 in 20), when acidulated with hydrochloric acid, should not be rendered turbid by the addition of 1 Ce. of potassium sulphate T.S. (absence of *barium*). If 0.3 Gm. of the well-dried salt be dissolved in about 50 Ce. of water, and 2 or 3 drops of potassium chromate T.S. be added, it should require not less than 24.6 Ce. nor more than 25.85 Ce. of tenth-normal silver nitrate T.S. to produce a permanent red color." *U. S.*

Uses.—When given to either cold or warm blooded animals in repeated doses of sufficient amount, potassium bromide produces a condition of universal depression, with failure of the circulation, progressively increasing paralysis, lowering of temperature, and finally death from asphyxia or exhaustion. In man the remedy causes similar results,—the series of phenomena being known as *bromism*. The symptoms are muscular weakness, general mental and bodily sluggishness, loss of memory, often marked sleepiness, depression of spirits deepening into complete apathy, lowering of temperature, and finally a universal depression of function, the patient lying in bed scarcely more than a feeble automaton. Fœtor of breath is usually well marked, and an eruption of acne may be the first indication of the constitutional action of the drug. In some cases the effects of the drug upon the skin are most marked, and the pustules, under its continuous exhibition, become furuncular or go on to ulceration. It seems to be proved that the bromide affects the whole nervous system, but

in the lower animals the portions most susceptible are those tissues of the spinal cord whose function it is to receive the impulse from without, and the peripheral ends of the afferent or sensitive nerves. Its action upon the circulation has not been clearly determined, but it is somewhat probable that in small doses it contracts, in large ones relaxes, the capillaries; in sufficient amount it lessens the force of the heart's beats. It is probably eliminated with all the secretions, having been found in the sweat, saliva, urine, and intestinal mucus. When taken largely for some time it accumulates in the system, and it has been found in the urine a month after the ingestion of the last dose. It has been employed in almost all diseases to which human flesh is heir, but experience has shown that it is chiefly valuable as a means of quieting non-inflammatory excitement of the reflex centres of the cord, of the peripheral afferent nerves, of the genital function, and of the cerebrum. It is especially valuable in *epilepsy*, in which disease, however, it is necessary to maintain its decided action for years. In various forms of *convulsions*, such as *hysterical*, *infantile*, and *puerperal*, it is often of great service. In *tetanus* and *strychnine poisoning*, if given with sufficient boldness, it is an excellent remedy. In general nervous excitement,—or unrest,—in *delirium tremens*, in *nymphomania*, *satyriasis*, and other forms of genital irritation without inflammation, and in *semi-impotence* from over-irritability of the sexual organs, it is of great service. Given with opium it will often avert the secondary nausea which that narcotic produces in some persons. In *reflex vomiting*, as that of pregnancy, it is often of advantage. According to J. T. Rothrock, it is of service in preventing the so-called *urethral fever* produced in some very susceptible males by the passage of a catheter or bougie. It was formerly used as an alternative and resolvent in *syphilis*, *scrofula*, *bronchocele*, and other affections, but this employment of it has passed entirely out of vogue.

Potassium bromide may be given, dissolved in water, in doses of from twenty grains to a drachm (1.3 to 3.9 Gm.) three times a day. In some cases much larger amounts are required. In severe strychnine poisoning a half-ounce (15.5 Gm.), properly diluted, may be exhibited at once, and in tetanus there is little use in giving less than the same amount in the twenty-four hours.

Dose, ten to twenty grains (0.65 to 1.3 Gm.).

POTASSII CARBONAS. U. S., Br.

POTASSIUM CARBONATE

(po-tās'sī-i cār'bo-nās)

$K_2CO_3 = 137.27$

"It should contain, when thoroughly dried, not less than 98 percent, of pure Potassium Carbonate $[CO(OK)_2]$, and should be kept in

well-stoppered bottles." U. S. "Potassium Carbonate, K_2CO_3 , associated with either one or two molecules of water. It may be obtained from the ashes of wood, or by interaction of crude potassium sulphate and crude calcium carbonate and carbon." Br.

Salt of Tartar. Carbonate of Potassa from Pearl-ash; Potassii Carbonas Purus, Sal Tartari; Kali Carbonicum. Carbonas Potassicus. s. Kallieus; Carbonate de Potasse pur, Sel de Tartre, Fr. Cod.; Kallium Carbonicum, P. G.; Kohlensaureskali, Kalliumcarbonat, G.; Carbonato di potassio, It.; Carbonato potassico, Sp.

The present U. S. Pharmacopœia does not give a process for this salt.

The object of the process¹ is to purify the impure potassium carbonate, or pearl-ash. This generally contains certain insoluble impurities, as well as small portions of potassium sulphate, silicate, and chloride, as explained under another head. (See *Potassii Carbonas Impura*.) By dissolving it in a due proportion of water, and filtering the solution, the insoluble impurities are disposed of, as well as the greater part of the foreign salts, which, being much less soluble than the potassium carbonate, are excluded by the superior affinity of this salt for the water. The proper way of conducting the purification is to mix the impure carbonate with an equal weight of cold water, and to allow the mixture to stand for a day or two, stirring it frequently to promote the action of the water. The clear liquor obtained by decantation or filtration is then evaporated to dryness. The former official process was conducted very much in this way, cold water being employed, and about equal weights of alkali and water being used. The prolonged contact of the water with the salt, and the occasional stirring of the mixture, formerly ordered by the Dublin College, were useful directions. In no case should the undissolved residue be washed with a fresh portion of water, as by such a proceeding the foreign salts, which it is the object of the process to separate, would be dissolved. Iron vessels are directed, because this metal is not acted on by the alkali, while glass is attacked by it. In granulating the salt by stirring, it is better, when the solution is brought nearly to dryness, to keep it on the fire at a reduced heat until the process is finished, than to remove it the moment it thickens. According to Berzelius, a more productive process for purifying pearl-ash, though the resulting salt is not so pure as when obtained in the way just described, is to dissolve the pearl-ash in more than its weight of water, to evaporate the solution until it has the sp. gr. 1.52, and then to put it in a cool place, that the foreign salts, principally potassium

¹ "Take of Impure Carbonate of Potassium [pearl-ash] thirty-six troyounces; Water two pints and a half. Dissolve the Impure Carbonate in the Water, and filter the solution; then pour it into an iron vessel, and evaporate over a gentle fire until it thickens. Lastly, remove it from the fire, and stir constantly with an iron spatula so as to form a granular salt." U. S. 1870.

sulphate and chloride, may crystallize. The solution is then decanted, and evaporated to dryness. To get rid of the silica, Rieckher proposes to evaporate the solution, exempt from sulphate, to dryness, to moisten the residue with solution of ammonium carbonate, and again evaporate. The silica separates, and passes into the insoluble state at the temperature necessary for evaporation. By again dissolving and evaporating, the carbonate is obtained free from this impurity. (*Chem. Cb.*, 1863, p. 158.)

Properties.—It is officially described as “a white, granular powder, odorless, and having a strongly alkaline taste; very deliquescent. Soluble in 0.91 part of water at 25° C. (77° F.), and in about 0.65 part of boiling water; insoluble in alcohol. When heated to 130° C. (266° F.), the salt loses all the water which it may have retained or absorbed; at a bright red heat it melts, and at a white heat it volatilizes, communicating to a non-luminous flame a pure violet color. Its aqueous solution (1 in 20) has a strongly alkaline reaction upon red litmus paper, and effervesces with acids. Its aqueous solution (1 in 10) yields with excess of tartaric acid T.S. a white crystalline precipitate.” *U. S.* It is extremely deliquescent, and hence a portion of it, exposed to the air for some time, attracts so much water as to dissolve completely into an oily liquid, called by the older chemists *oleum tartari per deliquium*. On account of this property, potassium carbonate should be kept in bottles with accurately ground stoppers. The usual impurities are earthy matters, potassium sulphate and chloride, and silica in the state of potassium silicate.

Tests.—“No residue should be left on dissolving 1 Gm. of the salt in 20 Cc. of water (absence of *earthy impurities*). An aqueous solution of Potassium Carbonate (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If 5 Cc. of the aqueous solution (1 in 20) be carefully mixed with an equal volume of concentrated sulphuric acid, and, after cooling, 3 Cc. of ferrous sulphate T.S. be poured upon it so as to form a separate layer, no brown color should appear at the line of contact (absence of *nitrate*). One Gm. of Potassium Carbonate, weighed after having been thoroughly dried at 130° C. (266° F.), and dissolved in about 50 Cc. of water, should require not less than 14.3 (14.38) Cc. of normal sulphuric acid V.S. for neutralization, methyl-orange T.S. being used as indicator.” *U. S.* The official test permits the presence of 2 per cent. of impurities. It is incompatible with acids and acidulous salts, ammonium chloride and acetate, lime water, calcium chloride, magnesium sulphate, alum, tartar emetic, silver nitrate, ammoniated copper and ammoniated iron, ferrous sulphate, tincture of ferric chloride, calomel and corrosive sublimate, lead acetate and subacetate, and zinc sulphate. It is not de-

composed by iron and potassium tartrate. “Each gramme should require for neutralization at least 11.9 Cc. of volumetric solution of sulphuric acid. 2 grammes, after exposure to a red heat, should leave between 1.66 and 1.7 grammes of anhydrous potassium carbonate, K_2CO_3 .” *Br.* A solution of the salt, on exposure to the air, or on addition of an acid, deposits flocculi consisting of hydrated silica, resulting from the decomposition of potassium silicate, which is always present as an impurity. The spontaneous deposition of silica is owing to the absorption of carbon dioxide.

Composition.—Potassium carbonate, after exposure to a red heat, is anhydrous, consisting of two atoms of potassium and one carbonic acid group, CO_3 . Obtained by the usual processes, it contains two molecules of potassium carbonate and three of water. When exposed to the air, potassium carbonate absorbs sufficient water, before losing its solid form, to give it three molecules; with more it begins to deliquesce. (Pohl, *A. J. P.*, 1861, p. 532.) *Potassium percarbonate*, $K_2C_2O_6$, was made by Constans and von Hansen by electrolyzing a saturated solution of potassium carbonate, and gradually lowering the temperature. It is a bluish amorphous powder, hygroscopic and decomposing water at ordinary temperatures, bicarbonate being formed. (*Chem. News*, 1897, 170; 1898, 65.)

Uses.—Purified pearlash is the form of potassium carbonate usually employed in this country, where it is frequently, though incorrectly, called *salt of tartar*, the latter name being strictly applicable to the purer carbonate obtained by decomposing cream of tartar. It is occasionally used as an antacid in *dyspepsia*, a diuretic in *dropsy*, and an antilithic in *uric acid gravel*, but the purpose to which it was most commonly applied in former years was the formation of the *neutral mixture* and the *effervescing draught*. It is also useful in some cases of *jaundice*, directly exciting the hepatic function. It should always be administered in dilute solution. In large quantities it acts as a corrosive poison, and is capable of producing death in a few hours; three ounces in very concentrated solution have been recovered from by an adult female. (Espagne, *A. G. M.*, Fév. 1867.) The antidotes are the fixed oils and the vegetable acids. As a local remedy in *cutaneous affections*, potassium carbonate is used in the form of bath, lotion, and ointment. From eight to sixteen ounces may be used for a single bath, the quantity being gradually increased. Lotions may be made by dissolving two or three drachms in a pint of water; and ointments, by rubbing from ten grains to a drachm with an ounce of lard.

Dose, ten to thirty grains (0.65 to 2.0 Gm.).

POTASSII CARBONAS IMPURA.

U. S. 1870.

IMPURE CARBONATE OF POTASSIUM

(pō-tās'sī-i cār-bō-nās im-pū'rā)

Pearlash, Pearlashes, Impure Potassa; Potasse du Commerce, *Fr.*; Rohe Pottasche, *G.*; Potasch, *Dutch*; Potaske, *Dan.*; Potaska, *Swed.*; Potassa del commercio, *It.*; Cenizas claveladas, *Sp.*

The alkali called potassa is the hydroxide of the metal potassium. (See *Potassium.*) It exists in various states of purity admixed with carbonate. In its most impure state, it is the common potash or *potashes* of commerce. This, subjected to calcination, is rendered purer, and is then called *pearlash*, the form of the alkali designated by the name at the head of this article.

Natural State and Preparation.—Potash and pearlash of commerce were formerly procured largely from the ashes of wood by lixiviation, and the subsequent evaporation of the solution obtained. The alkali exists in the wood principally in the state of acetate, and, being of a

pots, where it congeals in cakes. These are broken up and packed in tight barrels, and constitute the *potash* of commerce. If it is intended to make *pearlash*, the process is varied. In this case the black matter of the consistence of brown sugar, called *black salts* by our manufacturers, instead of being fused, is transferred from the kettles to a large oven-shaped furnace so constructed that the flame may play over the alkaline mass, which in the meantime is stirred by means of an iron rod. The ignition is in this way continued until the combustible impurities are burnt out, and the mass, from being black, becomes of a bluish-white color.

The ashes of plants amount generally to not more than a few parts in the hundred, and of these a portion only consists of potassium hydroxide. The different parts of the same vegetable, and, for a stronger reason, different plants, furnish variable quantities of ashes. Ligneous plants yield less than herbaceous, the trunk less than the branches, and the branches less than the leaves. The bark yields more ashes than the wood, and the leaves of trees which drop their foliage in winter yield more than the leaves of evergreens. The table below gives the number of parts of potassium hydroxide contained in the ashes of one thousand parts of the plants.

Pine	0.45	Wheat straw	4.18	Dry oak leaves	24.0
Poplar	0.75	Flax	5.0	Common nettle	25.0
Birch	1.29	Rush	5.08	Black elder	25.5
Beech	1.45	Common thistle	5.37	Vetch	27.5
Oak	2.03	Vine branches	5.5	Poke	45.6
Box	2.26	Barley straw	5.8	Wheat stalks	47.0
Willow	2.85	Beech bark	6.0	Stems of potatoes	58.0
Linden	3.27	Fern	6.2	Wormwood	73.0
Elm	3.9	Indian corn stalks	17.5	Fumitory	79.0
Maple	3.9	Sunflower stalks	19.4	Angelica	96.2

fixed and incombustible nature, is left behind after the incineration. The wood is burned on the ground, in a place sheltered from the wind. The ashes consist of a soluble and an insoluble portion. The soluble part is made up of potassium carbonate, together with potassium sulphate, phosphate, and silicate, and potassium and sodium chlorides; the insoluble portion, of calcium, and aluminum salts, oxidized iron and manganese carbonate and phosphate, and a little carbonaceous matter that has escaped combustion. The ashes are lixiviated in barrels with the addition of a portion of lime, and the soluble substances above mentioned are taken up. The lixivium is then evaporated in large iron kettles, which for several days are kept constantly full. The evaporation is continued until the mass has become of a black color and of the consistence of brown sugar. It is now subjected to as powerful a heat as can be produced by the best wood fire for a number of hours, by which it is fused. During the fusion the combustible impurities are for the most part burnt out, and a gaseous matter is emitted, which agitates the more fluid part. When the fusion is complete, the liquid becomes quiescent, and looks like melted iron. It is now transferred, by means of large iron ladles, to iron

Commercial History.—Potash and pearlash have been made in those countries in which forests abound. Accordingly, the alkali has been extensively manufactured in Canada. In the United States, with the disappearance of our forests, its production has been greatly curtailed. While the exports at one time were very large, they have diminished so that in 1904 only 1,027,181 lbs., valued at \$56,800, were exported, and in 1905, 548,432 lbs., valued at \$31,346.

Some idea of the falling off in manufacture may be gained by comparing this output with that of 1850, the year of greatest production, when 27,000,000 lbs. were exported from Canada alone. (See an interesting report on "Canadian Potash," by T. D. Reed, *Proc. A. Ph. A.*, 1893, 126.) It is produced in considerable quantities in the northern countries of Europe, especially in Russia and on the shores of the Baltic. It is of different qualities as it occurs in commerce, and is distinguished by the country or place of manufacture, as *American*, *Russian*, *Dantzic potash*, etc. Within recent years the residues of beet root molasses, after fermentation of the sugar and distillation of the spirit, have served as a source of potash. It is thus obtained in large quantity in Germany and France.

The *suint* of sheep's wool constitutes another source of potashes. Potassium sulphate, either the crude salt from the Stassfurt deposits or that obtained from the crude potassium chloride of the same locality, is also converted into carbonate by a process analogous to Leblanc's soda process. The principle of the ammonia soda process can also be applied to the crude potassium chloride of Stassfurt, with this difference in the practical operation, that, because of the ready solubility of the acid potassium carbonate, trimethylamine is used instead of ammonia, as the chloride of this base is much more soluble than is ammonium chloride. Crude potash is now prepared in largest amount from the "abraum" salts of the German rock salt deposits, in a manner analogous to the preparation of sodium carbonate from sodium chloride. The mixture of magnesium and potassium chlorides found so abundantly in these deposits may also be saturated with carbon dioxide, when an insoluble double salt, $\text{MgCO}_3 + \text{KHCO}_3 + 4\text{H}_2\text{O}$, separates out. By heating this with water under pressure it decomposes into insoluble magnesium carbonate and soluble potassium carbonate, which remains in solution and is obtained therefrom by evaporation. Other minerals have also become the source of potassium salts, especially a deposit of mixed potassium and magnesium chlorides, overlying a bed of common salt, at Stassfurt, near Madgeburg, in Prussia. The production of the most important of these potash minerals at Stassfurt for 1904 was in metric tons as follows: potassium chloride, 297,238, valued at \$8,850,500; kainite, 1,905,843, valued at \$6,641,250; other potassium salts 2,179,471 tons, valued at \$5,573,500.

Properties.—Potash is in the form of fused masses, of a stony appearance and hardness, and a caustic burning taste. Its color is variegated, but reddish and dark brown are the predominant hues. When exposed to the air, it absorbs moisture and deliquesces, and, if sufficiently long exposed, finally becomes liquid. Pearlsh is of a white color, with usually a tinge of blue. As it occurs in commerce, it is in tight casks, containing about three hundred and fifty pounds, in which it forms one entire, hard, concrete mass. In commerce it is found in coarse powder, intermingled with lumps as dug out of the casks, presenting an opaque granular appearance, like table salt or common sugar. It is deliquescent, and has a burning alkaline taste. It is soluble in water, with the exception of impurities. The soluble matter in 100 grains of the salt of medium quality will neutralize about 58 grains of official sulphuric

acid. It differs from potash principally in containing fewer combustible impurities and in being less caustic and deliquescent. The coloring matter of both these forms of alkali is derived from carbonaceous impurities and small portions of iron and manganese.

Composition.—The basis of both potash and pearlsh is potassium carbonate, but this is associated with certain salts and with insoluble impurities. Several varieties of potash found in commerce were analyzed by Vauquelin, whose principal results are contained in the table below. The quantity examined of each kind was 1152 parts.

These results, calculated for 100 parts, show that the American potash contains 74 per cent. of pure alkali hydroxide and the Russian 67 per cent. Pearlsh, it is seen, is more rich in carbonic acid than potash, and this result of analysis corresponds with the qualities of the two substances as prepared in the United States,—potash being known to be far more caustic than pearlsh. Besides the impurities shown by the table, potassium phosphate and silicate and sodium chloride are present. J. U. Lloyd, in the *Proc. A. Ph. A.*, 1892, p. 190, gives the results of an examination of American commercial potashes; he found that what was sold in the market as "first sorts" was largely adulterated with common salt, this addition made to the melted potash in the kettle tending to whiten the crude potash and give it increased value in the eyes of those consumers who judge merely by appearance and do not take the trouble to assay it. According to Stevenson Macadam, the potashes of commerce contain iodine and a trace of bromine, which shows that the forest trees from which the alkali is obtained must contain a very minute proportion of these non-metallic elements.

As the potash of commerce is valuable in the arts in proportion to the quantity of real alkali which it contains, it is important to possess an easy method of ascertaining its quality in that respect. (See *Potassii Hydroxidum*.)

Pearlash, from its impurity, is never used as a medicine. Purified to a certain extent, it takes the name of potassium carbonate. (See *Potassii Carbonas*.)

POTASSII CHLORAS. U. S., Br.

POTASSIUM CHLORATE

(pō-tās'sī-i chlō'rās)

$\text{KClO}_3 = 121.68$

"It should contain not less than 99 percent. of pure Potassium Chlorate $[\text{ClO}_2.\text{OK}]$, and

KINDS OF POTASH.	Potassium Hydroxide.	Potassium Sulphate.	Potassium Chloride.	Insoluble Residue.	Carbon Dioxide and Water.
American potash	857	154	20	2	119
Russian potash	772	65	5	56	254
Pearlash	764	80	4	6	308
Dantzic potash	608	152	14	79	304

should be kept in well-stoppered bottles. *Great caution should be observed in handling it*, as dangerous explosions are liable to occur when it is heated or subjected to concussion or trituration with organic substances (cork, tannic acid, sugar, etc.), or with sulphur, antimony sulphide, phosphorus, or other easily oxidizable substances." *U. S.*¹ "Potassium Chlorate, KCl Os, is obtained by passing chlorine into water holding lime or magnesia in suspension, treating the clarified liquid with potassium chloride, and subsequently crystallizing the potassium chlorate." *Br.*

Chlorate of Potash; Kali Oxymuriaticum, Kali Muriaticum Oxygenatum, Chloras Potassicus, s. Kalliscus; Hyperoxymuriate of Potassa; Chlorate de Potasse, *Fr. Cod.*; Kalium Chloricum, *P. G.*; Kaliumchlorat, Chlorsaures Kali, *G.*; Clorato di potassio, *It.*

In the U. S. and Br. Pharmacopœias no processes are given for potassium chlorate.

Preparation.—The salt may be obtained by the process of Graham, which consists in mixing potassium carbonate with an equivalent quantity of calcium hydroxide before submitting it to the action of chlorine. The gas is absorbed with avidity, and the mass becomes hot, while water is given off. The lime converts the carbonate into potassium hydroxide, and the reaction then takes place between six molecules of potassium hydroxide and six atoms of chlorine, with the result of forming five molecules of potassium chloride and one of potassium chlorate, while three molecules of water are eliminated.

The products are, therefore, calcium carbonate, potassium chloride, and potassium chlorate. The chloride and chlorate are separated from the carbonate by solution in hot water, and the chlorate from the chloride by priority of crystallization; a large proportion of the potassium hydroxide is lost by being converted into potassium chloride. In the process now generally employed for the commercial manufacture of potassium chlorate this is obviated, as follows. Chlorine is passed into a solution of milk of lime having a specific gravity of 1.04 until the liquid is nearly saturated. The clear solution is evaporated until it has a specific gravity of 1.18, and then potassium chloride added, and the mixture boiled down until a specific gravity of 1.28 is attained. On cooling, crystals of potassium chlorate separate out. The reactions here are

Pechiney's improvement on this process is to separate the greater part of the calcium chloride from the calcium chlorate before adding the potassium chloride. For details, see *N. R.*, Feb. 1882.

The potassium chlorate of commerce is also prepared by the reaction of solutions of potassium chloride and calcium hypochlorite, with the assistance of heat. The potassium chlorate crystallizes during the refrigeration of the liquor, and calcium chloride remains in solution:

This process has been further improved in Muspratt and Eschellmann's English patents (*J. Soc. Chem. Ind.*, iii. pp. 349 and 445) by substituting magnesia for lime, as potassium chlorate is much less soluble in magnesium chloride solutions than in those of calcium chloride, and consequently much less chlorate is left in solution. The process is said to increase the production of chlorate by from 15 to 20 per cent. For a full account of the improved methods, see *Thorpe's Dictionary of Applied Chemistry*, 1891, vol. i. 531. See also *J. Chem. S.*, lxx. 517. Potassium chlorate is also now made on a commercial scale by the electrolysis of potassium chloride solution, two companies having begun operations at Niagara Falls, while several others are operating under different patents in Europe. The potassium chloride, on electrolysis in a cell without diaphragm, yields first potassium hypochlorite, but as the temperature of the bath is kept above 50° C., it is changed to a mixture of chlorate and chloride, from which, on cooling, the former crystallizes out.

Properties.—Potassium chlorate is in "colorless, lustrous, monoclinic prisms or plates, or a white, granular powder; odorless, and having a cooling, characteristic taste. Permanent in the air. Soluble in 16 parts of water at 25° C. (77° F.), and in 1.7 parts of boiling water; insoluble in absolute alcohol and but slightly soluble in diluted alcohol. At 334° C. (633.2° F.) the salt fuses, and above 352° C. (665.6° F.) it is decomposed into oxygen and potassium perchlorate; above 400° C. (752° F.) all of its oxygen is liberated, and a white residue of potassium chloride remains, amounting to 60.8 percent. of the pure Chlorate employed. This residue is readily soluble in water, and the solution yields a white, curdy precipitate with silver nitrate T.S. The aqueous solution of the salt (1 in 20) is neutral to litmus paper. With excess of tartaric acid T.S., the solution (1 in 20) slowly yields a scant, white, crystalline precipitate; with platinic chloride T.S., a yellow crystalline precipitate is produced. When heated with hydrochloric acid, the aqueous solution (1 in 20) assumes a greenish-yellow color, and evolves chlorine. The aqueous solution of the salt (1 in 20) should not become discolored upon the addition of ammonium sulphide T.S. (absence of heavy metals). If to 1 Gm. of Potassium Chlorate contained in a test-tube of about 40 Cc. capacity, 5 Cc. of water, 5 Cc. of potassium hydroxide T.S., and about 0.2 Gm. of aluminum wire be added, and if in the upper portion of the test-tube a pledget of purified cotton be inserted, and over the mouth there be

¹ Tablets composed of potassium chlorate and ammonium chloride have been known to explode violently after having been made some time, evidently on account of chemical decomposition and the sudden evolution of a large quantity of the gaseous constituents.

placed a piece of moistened red litmus paper, then if the tube be heated upon a water-bath for fifteen minutes, no blue coloration of the paper should be discernible (limit of *nitrates* and *nitrites*)." *U. S.* "In colorless monoclinic crystals with a cool saline taste, soluble in 16 parts of cold and 3 parts of boiling water. Moistened with *hydrochloric acid* it evolves a yellow gas consisting of a mixture of chlorine and chloric oxide. When heated it fuses, gives off oxygen gas, and leaves a white residue soluble in water, forming a solution which affords the reactions characteristic of potassium and of chlorides." *Br.* Potassium chlorate is characterized also by becoming first yellow and then red by admixture with a little sulphuric acid, and by the action of that acid evolving chlorine tetroxide (Cl_2O_4), known by its yellow color, and its explosive property when heated; by its bleaching power when mixed with hydrochloric acid and then with water, and by its property of exploding violently when triturated with a small portion of sulphur or phosphorus or kermes mineral. Potassium chlorate consists of one atom of potassium in combination with the chloric acid group. This salt is an excellent test of manganese existing in organic matter. If a small portion of such matter, containing even a trace of manganese, be thrown on the surface of the pure melted salt in a test-glass, after the combustion has ceased the cooled saline mass will be found to have a rose or pinkish tint, caused by the formation of potassium permanganate. (*Neues Repert.*, vi. 247.) A similar discoloration of the salt, produced by the use of pure charcoal in the same manner, will evince the presence of manganese in the chlorate as an impurity.

Uses.—Owing to the assertion of O'Shaughnessy that under the use of potassium chlorate all the blood of the body becomes florid, it was long supposed that the salt acts upon the system as an oxidizing agent. Isambert, however, has found the statement of O'Shaughnessy incorrect, and as the chlorate does not naturally part with its oxygen at the temperature of the body, and as it is eliminated from the kidneys unchanged, it is evident that it has not the specific action claimed for it. It is more irritant than most of the other potassium salts, and probably acts less powerfully as a cardiac depressant than do most of them. It is efficient in the *follicular* and even the *gangrenous stomatitis* of childhood, and in *mercurial ptyalism*, acting, however, only by its local influence, it being continually eliminated with the saliva and coming in perpetual contact with the mucous membrane of the mouth. It is much employed in *scarlatina* and *diphtheria*, but has no specific action in these affections, being useful only by its direct influence upon the mucous membrane affected. In *scurvy*, *phthisis*, and the various *dyscrasie* in which it was once employed, it is of no service.

As an alterative stimulant local application, potassium chlorate is often very useful in inflammations of the mucous membrane, such as *stomatitis*, *pharyngitis*, *urethritis*, *vaginitis*, *chronic cystitis*, etc., as well as in indolent ulcers either upon the surface of the body or in such interior portions as can be reached. Its saturated solution given by injection with laudanum, twice daily, is an excellent remedy for *hemorrhoids*. As a prophylactic in salivation five to ten grains (0.32 to 0.65 Gm.) may be given. Taken to the extent of five drachms (19.4 Gm.) in twenty-four hours, it has been found to produce diuresis, abundant salivation, and a strong saltish taste. Such an amount as this is, however, dangerous even for the adult. When used as a wash or an injection, from a drachm to half an ounce (3.9 to 15.5 Gm.) of the salt may be dissolved in a pint (472 Cc.) of water. A solution in glycerin, in the proportion of one part of the salt to ten parts of the menstruum, has been especially recommended as a dressing for *ill-conditioned wounds and ulcers*. The remedy has also been applied in the form of very fine powder dusted on the surface.

In overdose potassium chlorate is an active poison, four drachms of it having caused death in the adult. The symptoms produced were violent vomiting, profuse diarrhoea, excessive dyspnoea, great failure of the heart's action, and marked cyanosis. The urine is lessened in quantity, albuminous, often of a dark reddish-brown or blackish color, and containing tube casts and the débris of blood corpuscles. In some cases there have been marked nervous symptoms, such as cramps, delirium, coma, etc. The lesions found after death are those of gastro-enteritis and acute nephritis, with alteration in the character of the blood due to the development in it of methæmoglobin. On account of their irritant action on the kidneys, large doses are especially dangerous in *diphtheria*.

Dose, from five to fifteen grains (0.32 to 1.0 Gm.).

Off. Prep.—Liquor Chlorig Compositus, *U. S.*; Trochisci Potassii Chloratis, *U. S.* (*Br.*).

POTASSII CITRAS. U. S., Br.

POTASSIUM CITRATE

(pō-tās'si-i cī'trās)

"It should contain not less than 99 percent. of pure Potassium Citrate [$\text{C}_6\text{H}_4(\text{OH})(\text{COO K})_3 + \text{H}_2\text{O}$], and should be kept in well-stoppered bottles." *U. S.* "Potassium Citrate, $\text{C}_6\text{H}_4\text{OH}(\text{COOK})_3$, is prepared by the interaction of citric acid and potassium carbonate." *Br.*

Kallum Citricum, Citras Potassicus, *g.* Kallcus; Citrate of Potash; Citrate de Potassé, *Fr.*; Kallum-citrat, Citronsaures Kall, *G.*

Potassium citrate was known formerly by the name of *salt of Riverius*. In the U. S. formula of 1870,¹ mutually saturating proportions of the acid and bicarbonate were intended to be employed, the latter ingredient being preferred to the carbonate on account of its greater purity. The potassium of the bicarbonate unites with the citric acid to form the potassium citrate, and the carbon dioxide escapes, producing effervescence. The resulting solution is directed to be evaporated to dryness, as affording the most convenient form for use. The granulation ordered has a tendency to retard the deliquescence of the citrate. The British 1885 process differed only in the use of the carbonate instead of the bicarbonate, and in providing more carefully for an exact neutralization.

Properties.—Potassium citrate is crystallizable, but, as usually seen, is in the form of a granular powder. The U. S. P. recognizes both forms, and describes it as in "transparent, prismatic crystals, or a white, granular powder, odorless, and having a cooling, saline taste. Deliquescent when exposed to the air. Soluble in about 0.5 part of water at 25° C. (77° F.), and very soluble in boiling water; sparingly soluble in alcohol. When heated above 100° C. (212° F.), the salt begins to lose water; at 200° C. (392° F.) the water of crystallization (5.55 percent.) is completely lost. At 230° C. (446° F.) the salt begins to decompose, turns brown, and at a higher temperature carbonizes and emits inflammable gases which have a very pungent, acid odor. At a red heat a blackened mass of potassium carbonate and carbon is left, which has an alkaline reaction, and strongly effervesces with acids. The aqueous solution of the salt is alkaline to red litmus paper, but does not affect phenolphthalein. An aqueous solution of Potassium Citrate yields a white, crystalline precipitate with sodium bitartrate T.S. On mixing 10 Cc. of the aqueous solution of the salt (1 in 20) with 10 Cc. of calcium chloride T.S., the liquid remains clear until it is boiled, when a white, granular precipitate is produced. The aqueous solution of the salt (1 in 20), slightly acidulated with acetic acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). A solution of 1 Gm. of Potassium Citrate in 1 Cc. of water, should not deposit any precipitate on the addition of 1 Cc. of acetic acid (absence of *tartrate*). If 1 Gm. of Potassium Citrate be thoroughly carbonized at a temperature not exceeding red heat, and the residue extracted with boiling distilled water, until the washings cease to react with methyl-orange T.S., the mixed

filtrate and washings should require for complete neutralization not less than 18.4 Cc. of half-normal hydrochloric acid V.S., methyl orange T.S. being used as indicator." U. S.

The British Pharmacopœia gives the following tests of its character. "A white powder of saline feebly acid taste, deliquescent, very soluble in water. It affords the reactions characteristic of potassium salts and of citrates. Each gramme of the dry salt, heated to redness till gases cease to be evolved, should leave an alkaline residue, which when treated with water, filtered, and well washed, should yield a clear solution requiring for neutralization at least 9.7 cubic centimetres of the *volumetric solution of sulphuric acid*. It should yield no characteristic reaction with the tests for lead, iron, calcium, magnesium, sodium, carbonates, or tartrates, and only the slightest reactions with the tests for chlorides or sulphates." Br.

As citric acid is tribasic, this salt consists of three atoms of potassium combined with the citric acid radical $C_6H_5O_7$, and with this one molecule of water, its formula being $K_3C_6H_5O_7 \cdot H_2O$.¹

Uses.—Potassium citrate is a grateful refrigerant diaphoretic, and has long been used in the *fevers* of this country, in the extemporaneous forms of neutral mixture and effervescing draught. As these require time and a somewhat careful manipulation in their preparation, it has been found more convenient to keep the potassium citrate ready made and dissolve it in water when wanted for use. This solution will no doubt produce the essential diaphoretic and refrigerant effects of the neutral mixture or the effervescing draught, but is less agreeable to the stomach and palate, because destitute of the carbonic acid contained in these preparations. Potassium citrate dissolved in an excess of lemon juice affords the most agreeable method of securing the influence of an alkaline salt of potassium upon the system, as in *rheumatism*, the *uric acid diathesis*, etc. It is also a very valuable remedy in the first or dry stage of *acute bronchitis*.

Dose, of the citrate, from twenty to twenty-five grains (1.3 to 1.62 Gm.). When a decided effect upon the system is desired, as much as an ounce (31 Gm.) of it may be given in twenty-four hours.

Off. Prep:—Liquor Bismuthi et Ammonii Citratis, Br.; Potassii Citras Effervescens, U. S.

¹ "Take of Citric Acid *ten troyounces*; Bicarbonate of Potassium *fourteen troyounces*; Water a *sufficient quantity*. Dissolve the Citric Acid in a pint of water, add the Bicarbonate of Potassium gradually, and, when effervescence has ceased, filter the solution and evaporate to dryness, stirring constantly, after a pellicle has begun to form, until the salt granulates. Keep it in a well-stopped bottle." U. S. 1870.

¹ *Sodium and Potassium Citrate*.—T. Push of Dessau, Germany, has made a complete series of citrates, corresponding to the official tartrates, with a view of finding a stable compound. He ascertained that the double sodium and potassium citrate is an extremely stable compound, even when exposed to the air for a long time. He prepares the salt by dissolving 100 parts of citric acid in water, adding 108 parts of pure potassium carbonate and 221 parts of crystallized sodium carbonate, filtering, evaporating, and crystallizing. The crystals are allowed to drain, and the mother liquor is further concentrated, until, on cooling, it solidifies to a crystalline mass, which is used in the condition of powder. (*A. Pharm.*, July, 1877, 47; *N. E.*, Sept. 1877.)

POTASSII CITRAS EFFERVESCENS.

U. S.

EFFERVESCENT POTASSIUM CITRATE

(pō-tās'si-i cī'trās ēf-fer-vēs'cēns)

* "Potassium Citrate, two hundred grammes [or 7 ounces av., 24 grains]; Sodium Bicarbonate, dried and powdered, four hundred and seventy-seven grammes [or 16 ounces av., 361 grains]; Tartaric Acid, dried and powdered, two hundred and fifty-two grammes [or 8 ounces av., 389 grains]; Citric Acid, uneffloresced crystals, one hundred and sixty-two grammes [or 5 ounces av., 313 grains], to make about one thousand grammes [or 35 ounces av., 120 grains]. Dry the Potassium Citrate on a water-bath, until it ceases to lose weight; after powdering the dried salt, mix it intimately with the powdered Citric Acid and Tartaric Acid, then thoroughly incorporate the Sodium Bicarbonate. Place the mixed powders on a plate of glass or in a suitable dish, in an oven heated between 93° and 104° C. (199.4° and 219.2° F.). When the mixture, by the aid of careful manipulation with a wooden spatula, has acquired a moist consistence, rub it through a No. 6 tinned-iron sieve, and dry the granules at a temperature not exceeding 54° C. (129.2° F.). Keep the product in well-stoppered bottles." U. S.

The process of the U. S. P. (8th Rev.) differs from that formerly official, mainly in the absence of sugar which has a tendency to discolor and the use of potassium citrate instead of potassium bicarbonate and citric acid.

This official effervescent salt affords an agreeable mode of administering potassium citrate.

Dose, from one to two teaspoonfuls, in cold water.

POTASSII CYANIDUM. U. S.

POTASSIUM CYANIDE

(pō-tās'si-i cŷ-ān'ī-dŭm)

KCN = 64.70

"It should contain not less than 95 percent. of pure Potassium Cyanide, and should be kept in well-stoppered bottles." U. S.

Cyanide of Potassium; Potassii Cyanuretum, U. S. 1850; Cyanuret of Potassium; Cyanure de Potassium, Fr. Cod.; Kalium Cyanatum, Cyanuretum Potassium, s. Kalicum; Kaliumcyanid, Cyankalium, G.; Clanuro potasico, Sp.

The process of the U. S. P. 1870¹ was that of F. & E. Rodgers, though generally known under

the name of Liebig. It furnishes a large product, a considerable part of which is the impurity potassium cyanate. The reaction takes place between one molecule of potassium ferrocyanide and one of potassium carbonate. The iron is set free, the carbon dioxide is evolved, and five molecules of potassium cyanide and one of potassium cyanate are formed. The iron occupies the lower part of the fused liquid, and, if the latter be carefully poured out to solidify, the portion contaminated with the iron may be left behind. The reaction is explained by the following equation:

Fordos and Gélis, in an able paper contained in the *Journal de Pharmacie* for Aug. 1857, pointed out numerous causes which contribute to render the salt, as obtained by the use of potassium carbonate, impure. The commercial cyanide, which is obtained by this process, was found by these writers to be very impure, containing only from 36 to 55 per cent. of the pure salt. The potassium cyanate may be readily detected by saturating the product with an acid, which will cause an effervescence of carbon dioxide and the generation of a salt of ammonium. According to Schwarz, it may be freed from potassium cyanate and carbonate by treating the impure cyanide with carbon disulphide, which dissolves it, and may be recovered in great measure by distillation. (*Chem. News*, No. 190, p. 41.)

In the process in which the potassium ferrocyanide is ignited alone (U. S. process 1840), the salt is first deprived of its water of crystallization by exposure to a moderate heat, and then calcined at a red heat for two hours, in order to decompose the ferric cyanide. The reaction which takes place is as follows:

The product of the calcination is a black, porous mass, consisting of potassium cyanide, mixed with carbide of iron and charcoal. As the cyanide is very prone to absorb oxygen, especially when hot, whereby it is decomposed, atmospheric air is excluded from the retort while it is cooling, by luting its orifice. When the whole is cold, the black mass is reduced to coarse powder, and exhausted by cold distilled water, which dissolves the potassium cyanide and leaves the carbide of iron and charcoal behind. The filtered liquor, therefore, is an aqueous solution of potassium cyanide, which is obtained in a solid state by a rapid evaporation to dryness. During the evaporation a small portion of the cyanide is decomposed, attended with the evolution of ammonia and the production of potassium formate. A portion of this salt, therefore, contaminates the cyanide, as obtained by this process; but the quantity is too small to interfere with its medicinal action. The decomposition here referred to takes

precipitated iron. Break up the mass while yet warm, and keep the pieces in a well-stopped bottle." U. S. 1870.

¹ *Potassium Cyanide*.—"Take of Ferrocyanide of Potassium, dried, eight troyounces; Pure Carbonate of Potassium, dried, three troyounces. Mix the salts intimately, and throw the mixture into a deep iron crucible previously heated to redness. Maintain the temperature until effervescence ceases, and the fused mass concretes, of a pure white color, upon a warm glass rod dipped into it. Then pour out the liquid carefully into a shallow dish to solidify, ceasing to pour before the salt becomes contaminated with the

place between one molecule of potassium cyanide and two of water, and is represented by the following equation:

This decomposition is avoided by exhausting the black mass with boiling alcohol of 60 per cent. (sp. gr. 0.896) instead of with water. The alcoholic solution, by evaporation to a pellicle, lets fall the salt upon cooling, as a crystalline precipitate, perfectly white and pure.

According to the process of the French Codex, which is that of Robiquet, this cyanide is obtained in the dry way, without the use of any solvent. The calcination is performed in a coated stoneware retort, half filled with the ferrocyanide, to which a tube is attached for collecting the gaseous products. When these cease to be disengaged, the heat is gradually raised to a very high temperature, at which it is kept for a quarter of an hour, after which the tube is closed with luting and the whole left undisturbed until quite cold. When the calcination is thus conducted, the retort, upon being broken, will be found to contain a black matter, covered with a fused layer of pure potassium cyanide, resembling white enamel. This is detached by means of a knife, and immediately transferred to a bottle with an accurately fitting stopper. The process of Wiggers consists in disengaging hydrocyanic acid from a mixture of potassium ferrocyanide and sulphuric acid and passing it into a cooled receiver containing an alcoholic solution of potassium hydroxide. The contents of the receiver ultimately form a solid magma of the cyanide, which is drained, washed several times with strong alcohol, pressed between folds of bibulous paper, and dried as quickly as possible. Potassium cyanide may be formed by passing a current of strongly heated nitrogen over charcoal impregnated with potassium carbonate and heated to a white heat. Potassium cyanide with some sodium cyanide admixture is made by the Niagara Electro-Chemical Co., who manufacture sodium by Castner's process. The manufacture of this sodium-potassium cyanide with the aid of sodium depends upon the fact that when the yellow prussiate of potash is heated with sodium neither oxygen nor alkaline carbonates are introduced, the product being an almost chemically pure mixture of sodium and potassium cyanide. This is sold in large amounts for the cyanide extraction process for gold now coming into extensive use. Still more recent is the manufacture of potassium and sodium cyanides under the patents of Adolph Frank in Germany. Calcium carbide reacts with atmospheric nitrogen to form calcium cyanamide, and this fused with alkaline chlorides or carbonates yields the corresponding cyanides. This will undoubtedly prove the cheapest manufacturing method.

Properties.—Potassium cyanide is in "white, opaque, amorphous pieces, or a white, granular

powder, odorless when perfectly dry; deliquescent in the air and exhaling the odor of hydrocyanic acid. *Great caution should be used in tasting and handling this salt.* Soluble in about 2 parts of water at 25° C. (77° F.). Boiling water dissolves its own weight of the salt, but rapidly decomposes it. In alcohol it is but sparingly soluble. At a low red heat the salt fuses. Its aqueous solution (1 in 20) has a strongly alkaline reaction upon red litmus paper, and emits the odor of hydrocyanic acid. With an equal volume of sodium bitartrate T.S. the solution yields a white, crystalline precipitate. With sodium cobaltic nitrite T.S. a copious yellow precipitate is produced. A few drops of a solution of the salt (1 in 20) yields with silver nitrate T.S. a white precipitate, which is soluble in an excess of the solution of Potassium Cyanide, also in ammonia water, and in concentrated nitric acid. If 5 Cc. of a solution of the salt (1 in 20) be shaken with a few drops of ferrous sulphate T.S. and of ferric chloride T.S., and a slight excess of hydrochloric acid then added, a blue precipitate (Prussian blue) will be produced.

The addition of diluted hydrochloric acid to the aqueous solution of the salt (1 in 20) should produce not more than a slight effervescence (limit of *carbonate*). After the diluted hydrochloric acid has been added in slight excess, a drop of ferric chloride T.S. should produce neither a blue color (absence of *ferrocyanide*) nor a red color (absence of *sulphocyanate*). If 1 Gm. of Potassium Cyanide be dissolved in sufficient distilled water to measure 100 Cc., then 64.7 Cc. of this solution mixed with 5 Cc. of ammonia water and 3 drops of potassium iodide T.S. should require not less than 47.5 Cc. of tenth-normal silver nitrate V.S. before the appearance of a permanent precipitate (each Cc. of the tenth-normal silver nitrate V.S. indicating 2 percent. of pure Potassium Cyanide)." *U. S.* If yellow, it contains iron. Its solution effervesces with acids. The salt and its solutions, when exposed to the air, exhale the odor of hydrocyanic acid, and become weaker; but the change takes place slowly. Orfila found that the salt, after fourteen days' exposure, by which it was almost entirely liquefied, still possessed energetic poisonous properties; he thinks, therefore, that the bad effects of opening the containing bottle, in dispensing the medicine, have been exaggerated. Unfortunately, the salt varies in quality independently of the effects of time and exposure. Besides water, the usual impurities are potassium hydroxide, carbonate, cyanate, and formate. They sometimes amount to half the weight of the cyanide, consisting principally of the carbonate. From the extensive use at present made of potassium cyanide in electro-metallurgy and photography, it is of importance to have a reliable test of its purity. Such a test has been discovered by Fordos and Gélis, founded on the fact that one molecule

of iodine rapidly reacts with one of the cyanide, so as to form a colorless compound, consisting of one molecule of potassium iodide and one of cyanogen iodide:

Accordingly, a tincture of iodine of known strength is gradually added to an aqueous solution of a given weight of the cyanide to be tested, until it assumes a permanent yellowish tinge, and the amount of iodine expended indicates the proportion of cyanide in the specimen. A necessary preliminary step, before using the tincture, is to add sufficient carbonic acid water to the solution of the cyanide to convert any potassium hydroxide or carbonate present into bicarbonate, in which state neither has any action on the iodine. This test is applicable to other cyanogen compounds which are soluble. Thornton J. Herapath's test for commercial potassium cyanide is a standard solution of copper ammonio-sulphate, the blue color of which is destroyed by a solution of the cyanide. The copper solution is added to one of the cyanide of known strength, until a faint blue coloration is produced, and the richness of the sample in pure cyanide is in proportion to the quantity of the copper solution required. Applying this test to five samples, Herapath found the proportion of pure cyanide to vary from 41 to 65 per cent. Potassium cyanide yields with silver nitrate added in excess a precipitate of silver cyanide, wholly soluble in ammonia and boiling nitric acid. It consists of one atomic group of cyanogen and one of potassium.

Besides the very extensive use of potassium cyanide in preparing electro-plating solutions for gilding and silvering by electro-deposition, and in photography, large quantities are now consumed in the extraction of gold and silver from the fine residues or "tailings" where amalgamation fails to take up the precious metals. From such solutions of gold in potassium cyanide the metal is thrown out by the action of metallic zinc.

Uses.—Potassium cyanide acts precisely like hydrocyanic acid as a poison and as a medicine. (See *Acidum Hydrocyanicum Dilutum*.) Five grains of it have repeatedly taken life, and hydrocyanic acid has been detected in the blood of a person who had been fatally poisoned by the cyanide. (Venghaus, *A. Pharm.*, clii. 138.) Potassium cyanide has the power of dissolving silver oxide and may be used for the removal of silver nitrate stains from clothing. According to Guthrie a solution of three grains (0.2 Gm.) to the ounce (30 Cc.), dropped in the eye every other day, will remove olive colored stains from the conjunctiva caused by silver nitrate. Owing to the large use of potassium cyanide for the recovery of gold, numerous accidental cases of poisoning occur in the reduction works. There is no satisfactory physiological antidote to potassium cyanide, the only remedy which offers much advantage being strychnine given hypodermically. A much

used chemical antidote is hydrogen dioxide solution. In employing it, the stomach should be freely washed out with a 30 per cent. dioxide solution. Martin and O'Brien (*Int. M. J.*, 1901) found that cobalt salts give stable solutions which instantaneously react with the cyanides even in the presence of hydrocyanic acid and would probably be an effective antidote were they themselves not very poisonous. Ferrous salts administered with an abundance of alkalies are efficacious, the ferrous cyanides being formed instantaneously.¹ These salts do not act, however, in the presence of free acid, so that it is essential to administer alkalies with them, magnesium oxide being especially useful.

Dose, one-eighth grain (0.008 Gm.).

POTASSII DICHROMAS. U. S. (Br.)

POTASSIUM DICHROMATE [Potassii Bichromas, Pharm. 1890, Potassium Bichromate]

(pō-tās'si-i dī-chrō'mās)

"It should contain not less than 99 percent. of pure Potassium Dichromate [$\text{Cr}_2\text{O}_7(\text{OK})_2$], and should be kept in well-stoppered bottles." U. S. "Potassium Bichromate, $\text{K}_2\text{Cr}_2\text{O}_7$, CrO_3 , is obtained by roasting chrome ironstone with lime in the presence of air, and by treating the resulting chromate with a potassium salt, and subsequently with an acid." Br.

Potassii Bichromas. Br.; Red Chromate of Potash (Potassa) Bichromate of Potash; Kali Bichromicum, Kali Bichromate Rubrum; Chromate (Bi) de Potasse, Fr. Cod.; Bichromate de Potasse, Fr.; Kallium dichromicum, P. G.; Kalliumdichromat, Zweifach Chromsaures Kali, Doppelchromsaures Kali, G.; Bichromato di potassio, It.; Bichromato potassico, Sp.

This salt is most conveniently prepared from the neutral or yellow *potassium chromate*, by acidulating its solution with sulphuric acid and setting it aside for a day or two. In the action which follows we may suppose two reactions take place:

Here the sulphuric acid, taking half the base from the two molecules of neutral chromate, changes them into two molecules of an acid chromate. This, however, is unstable, and the two molecules condense to form one of the dichromate with the elimination of one molecule of water. The yellow chromate is obtained by igniting four parts of powdered chrome-iron ore ($\text{FeO}, \text{Cr}_2\text{O}_3$) with one part of potas-

¹ The suggestion of Martin and O'Brien is that in all reduction works there should be kept a case containing the following: (1) 30 Cc. (1 oz.) of 23 per cent. solution of ferrous sulphate. (2) 30 Cc. (1 oz.) of 5 per cent. solution of potassium hydroxide. (3) 2 Gm. (30 grains) of powdered magnesium oxide. (4) Metal receptacle, 1 pint capacity. (5) A stomach tube. Numbers 1 and 2 being kept in hermetically sealed tubes, can be broken into the receptacle with the powdered magnesium and a half a pint of water and at once swallowed. The amount of antidote is theoretically sufficient for 5 Gm. of potassium cyanide, but should always be used in excess.

sium nitrate, and lixiviating the resulting mass with water. The solution, by evaporation, yields the yellow salt in crystals. In this process, the nitric acid of the potassium nitrate furnishes oxygen to convert the chromium sesquioxide into chromium trioxide, which then unites with the potassium of the same salt. The iron, in the mean time, is sesquioxided and rendered insoluble. Sometimes impure potassium carbonate (pearlash) is substituted for part of the potassium nitrate in the calcination. Omitting the potassium nitrate entirely, Stromeyer of Norway, in performing the ignition, has used lime along with the pearlash, with economical results. When lime is employed, calcium chromate is formed, which is extracted by lixiviation and decomposed by a soluble potassium salt, such as sulphate or carbonate, either of which will carry the lime out of solution. When desired, the dichromate may be obtained directly from the solution of potassium chromate, derived from the treatment of the ore by acidulating it with sulphuric acid, without first crystallizing it. The production of chrome ore in the United States has practically ceased, as the California deposits are no longer worked. The manufacture of potassium and sodium dichromates is therefore carried on with imported ore brought chiefly from Asia Minor and New Caledonia. The amount of the ore so imported in 1904 was 24,227 tons, valued at \$348,527.

Properties.—Potassium dichromate is in "large, orange-red, transparent, triclinic prisms, or four-sided tabular crystals, odorless, and having an acidulous, metallic taste. Permanent in the air. Soluble in about 9 parts of water at 25° C. (77° F.), and in 1.5 parts of boiling water; insoluble in alcohol. The salt fuses below a red heat, without loss of weight, forming a dark brown liquid. At a white heat it evolves oxygen and leaves a residue of neutral potassium chromate and green chromic oxide. The aqueous solution of Potassium Dichromate (1 in 20) has an acid reaction upon blue litmus paper. On mixing 4 Cc. of an aqueous solution (1 in 20) with 0.5 Cc. of alcohol, and then adding 1 Cc. of sulphuric acid, the liquid should assume a green color and emit the odor of aldehyde. Sodium cobaltic nitrite T.S. produces in an aqueous solution a copious yellow precipitate." U. S. "Potassium Bichromate dissolved in water gives a yellowish-white precipitate with solution of barium chloride, and a purplish-red precipitate with solution of silver nitrate, the filtrate from either solution affording the reactions characteristic of potassium, and each precipitate being entirely soluble in diluted nitric acid (absence of sulphates and chlorides). The aqueous solution, digested with sulphuric acid and ethylic alcohol, or with many other organic compounds, acquires an emerald-green color. 5.66 grammes of ferrous sulphate, dissolved in a little water and acidulated with sulphuric acid, should not cease to yield a blue color with solution of potassium

ferricyanide until such a quantity of solution as contains 1 gramme of the Potassium Bichromate has been added." Br.

Uses.—Potassium dichromate is an irritant caustic. It was first used internally in 1850, by Robin, as an alterative in *secondary syphilis*, in doses of one-fifth of a grain (0.012 Gm.), given in pill form, and Heyfelder of Erlangen, and Vicente afterwards employed it in the same disease with asserted encouraging results. It is said to cause salivation, but it is at present never used internally. Its saturated solution was recommended, in 1827, by Cumin, as a caustic application to *tubercular elevations, excrescences, and warts*, and in 1850 by Puche in *syphilitic vegetations*. It causes the morbid parts to shrivel and fall off. Dissolved in water, in the proportion of five grains gradually increased to a drachm to the fluidounce, it has been found useful in affections of the mucous membrane requiring astringents, and a solution has also been employed with advantage for correcting the fetor of *sloughing wounds*.¹

In overdoses it operates as a violent irritative and corrosive poison, producing severe vomiting, frequent dark hemorrhagic dejections, violent abdominal pains, pronounced disturbances of the circulation, coma, heart failure, collapse, etc. Less than an ounce has caused unconsciousness in five minutes, with death thirty-five minutes later. (B. M. J., ii. 1888.) Soap, an alkaline carbonate, or magnesia, is the antidote. Potassium dichromate is manufactured largely for the use of calico printers. The workmen engaged in making it are liable to painful ulcerations of the hands, and, in consequence of the acrid vapors evolved, violent irritation of the nostrils is apt to be experienced, with severe pricking sensations and excessive sneezing, followed in time by destruction of the mucous membrane and even of the septum itself. It is asserted that this result may be avoided by breathing through the mouth exclusively, the profuse secretion of saliva produced carrying off the poisonous particles. (B. F. M. R., Oct. 1863.) For a full account of the manufacture of the chromium salts, for dyes and pigments, see P. J. (xv. 32).

Dose, one-fifth of a grain (0.12 Gm.).

POTASSII ET SODII TARTRAS. U. S. (Br.)

POTASSIUM AND SODIUM TARTRATE
[Rochelle Salt]

(pō-tās'sī-i ēt sō'dī-i tār'trās)

"It should contain not less than 99 percent. of pure Potassium and Sodium Tartrate [C₂H₃

¹ Mueller's Fluid is used for preserving anatomical specimens. It consists of from 2 to 2.5 parts of potassium dichromate, 1 part of sodium sulphate, and 100 parts of water.

(OH)₂(COOK)(COONa) + 4H₂O], and should be kept in well-stoppered bottles." *U. S.* "Sodium Potassium Tartrate, (CHOH)₂COONa.COOK, 4H₂O, is prepared by neutralizing Acid Potassium Tartrate with Sodium Carbonate." *Br.*

Soda Tartarata, Br.; Sodæ et Potassæ Tartras, *Br.* 1864, *U. S.* 1850; Sodæ Potassio-tartras, Natro-kali Tartaricum; Tartarated Soda; Sal Polychrestum Seignetti, Tartaras Potassico sodicus; Tartrate de Potasse et de Soude, *Fr. Cod.*; Sel de Seignette, Soude Tartarisée, *Fr.*; Tartarus Natronatus, *P. G.*; Seignettesalz, Kaliumnatriumtartrat, *G.*; Tartrate sodico-potassico, *It.*; Tartrato sodico-potassico, *Sp.*

This salt cannot be made profitably on the small scale (for *U. S.* process 1870, see the footnote);¹ it is a double salt, consisting of a molecule of tartaric acid, C₄H₄O₆.H₂, in which one of the basic hydrogen atoms is replaced by potassium and the other by sodium. The theory of its formation is very simple, being merely the replacement of the hydrogen in the potassium bitartrate by the sodium of the sodium carbonate, the carbon dioxide of which escapes with effervescence. The quantities of the materials for mutual saturation are 123.19 parts of monohydrated carbonate and 373.56 of bitartrate, or one molecule of monohydrated sodium carbonate to two molecules of the acid tartrate.

Properties.—Potassium and sodium tartrate is in the form of "colorless, transparent, rhombic prisms, or a white powder, odorless, and having a cooling, saline taste. The crystals slightly effloresce in dry air. Soluble in about 1.2 parts of water at 25° C. (77° F.), and in less than 1 part of boiling water; almost insoluble in alcohol. When heated to 74° C. (165.2° F.), the salt fuses to a colorless liquid, which, at a higher temperature, froths, becomes brown, and gradually carbonizes, while inflammable vapors are emitted, having the odor of burning sugar. Finally, a black residue is left. The aqueous solution of the salt is feebly alkaline to litmus paper, but it does not affect phenolphthalein. An aqueous solution of the salt (1 in 10) yields, with an equal volume of acetic acid, a white, crystalline precipitate. With silver nitrate T.S. it produces a white precipitate which becomes black on boiling. The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for heavy metals (see PART III, Test No. 121). When heated with potassium hydroxide T.S., the solution should not evolve ammonia. If 1 Gm. of Potassium and Sodium Tartrate be thoroughly ignited at red heat, and the residue extracted with boiling distilled water, until the washings cease to

react with methyl-orange T.S., the mixed filtrate and washings should require, for complete neutralization, not less than 14.1 Cc. of half-normal hydrochloric acid V.S., methyl-orange T.S. being used as indicator." *U. S.* "Tri-metric prisms with hemihedral facets; it is entirely soluble in cold water; and has a saline taste. It affords the reactions characteristic of potassium, of sodium, and of tartrates. Each gramme, heated to redness until gases cease to be evolved, should leave an alkaline residue, which when treated with water, filtered, and well washed, yields a clear solution requiring for exact neutralization at least 7 cubic centimetres of the volumetric solution of sulphuric acid." *Br.*

When the salt is exposed to a very strong heat, it becomes blackened, and gives out inflammable gases with the odor of burnt sugar, the tartaric acid being destroyed, and a mixture of potassium and sodium carbonates left. It sometimes contains calcium tartrate, which may be removed by solution and crystallization, but when the crystals are large and well defined, it may be assumed to be pure. It is incompatible with most acids, and with nearly all acid salts except potassium bitartrate. It is also decomposed by lead acetate and subacetate, silver nitrate, and by the soluble calcium and barium salts, unless the solution of the tartrate be considerably diluted.

The way in which the acids act in decomposing potassium and sodium tartrate is by combining with the sodium, and throwing down potassium bitartrate as a crystalline precipitate. This double salt was discovered by Seignette, an apothecary of Rochelle, and hence is frequently called *Seignette's salt* or *Rochelle salt*.

Potassium and sodium tartrate consists of the tartaric acid group C₄H₄O₆, which is dibasic, in combination with one atom of potassium and one of sodium, together with 4 molecules of water.

Uses.—This salt is a mild, cooling purgative, well suited to delicate and irritable stomachs, being among the mildest and least unpalatable of the neutral salts. As it is not incompatible with tartar emetic, it may be associated with that salt in solution. It is an ingredient in the effervescent aperient called Seidlitz powders. (See *Pulvis Effervescens Compositus*.) When given in small and repeated doses it usually does not act as a purgative, but is absorbed and renders the urine alkaline. (Millon and Laveran, *J. P. C.*, 3e sér., vii. 222.)

Potassium and magnesium tartrate, formed by saturating cream of tartar with magnesium carbonate, has been proposed by Maillier for use as a safe, pleasant purgative. (*J. P. C.*, xiii.)

Dose, as a purge, from half an ounce to an ounce (15.5 to 31 Gm.).

Off. Prep.—*Pulvis Effervescens Compositus, U. S. (Br.).*

¹ "Take of Carbonate of Sodium twelve troyounces; Bitartrate of Potassium, in fine powder, sixteen troyounces; Boiling Water five pints. Dissolve the Carbonate of Sodium in the Water, and gradually add the Bitartrate of Potassium. Filter the solution, and evaporate until a pellicle begins to form; then set it aside to crystallize. Pour off the mother-water, and dry the crystals on bibulous paper. Lastly, evaporate the mother-water, that it may furnish more crystals." *U. S.* 1870.

POTASSII FERROCYANIDUM. U. S.

POTASSIUM FERROCYANIDE

(pō-tās'si-i fēr-ro-cy-ān'ī-dūm)

"It should contain not less than 99 percent. of pure Potassium Ferrocyanide, and should be kept in well-stoppered bottles." U. S.

Potassæ Prussias Flava; Ferrocyanide of Potassium; Yellow Prussiate of Potash; Cyanuretum Ferroso-potassium; Ferrocyanuret of Potassium; Ferrocyanide of Potassa, Prussiate of Potassa; Ferrocyanure de Potassium, *Fr. Cod.*; Protocyanure jaune de Fer et de Potassium, Prussiate jaune de Potasse, *Fr.*; Kalium Ferrocyanatum, Kalium Borussicum, Cyaneisenkalium, Ferrocyanikum, Gelbes Blutlaugensalz, *G.*

The yellow double potassium and iron cyanide is the salt from which potassium cyanide is obtained by calcination at a low red heat.

Potassium ferrocyanide is prepared on the large scale by heating animal matters, such as dried blood, hoofs, chips of horn, woollen rags, old leather, the refuse of tallow chandlers called *greaves*, and other substances rich in nitrogen, with the pearlash of commerce and scrap iron, in an egg-shaped iron pot called a shell, ladling out the pasty mass called the *melt*, and, after it has cooled sufficiently, dissolving it in water, and evaporating the solution so that crystals may form. The melt, while still hot, contains potassium cyanide only, the ferrocyanide being produced solely by the action of the water. The best temperature for making the solution is between 70° C. and 80° C. (158° F. and 176° F.); and the conversion of the cyanide into the ferrocyanide is facilitated by the presence of finely divided amorphous ferrous sulphide, and of potassium hydroxide. The reactions involved in the formation of the ferrocyanide are supposed to be

It has been sought to increase the yield of the ferrocyanide by avoiding the use of sulphur-containing materials and taking a relatively pure potash and fusing this first with the nitrogen-containing materials, and, after extracting with water from this fusion, to digest the liquors so obtained with ferrous hydroxide or carbonate, the reaction being

Some years ago this salt was manufactured by a process which dispensed with the use of animal matter, the necessary nitrogen being obtained by a current of atmospheric air. Fragments of charcoal, impregnated with 30 per cent. of potassium carbonate, were heated to a white heat in a cylinder through which a current of air was drawn by a suction-pump. This process is understood to have succeeded in a chemical sense, but failed on the score of economy, chiefly from the circumstance that the necessary fire-clay tubes could not be made to resist the combined action of the alkali and heat. In recent years since the introduction of

ferric hydroxide mass for purifying coal gas it has been found possible to extract the cyanides from the crude gas and produce from the purifying mass both yellow prussiate of potash and Prussian blue.

Properties.—Potassium ferrocyanide is in "large, soft, transparent, yellow, four-sided, monoclinic, tabular crystals or prisms; odorless, and having a mild, saline taste. Slightly efflorescent on exposure to the air. Soluble in about 4 parts of water at 25° C. (77° F.), and in 2 parts of boiling water; insoluble in alcohol. When heated to 60° C. (140° F.), the salt begins to turn white from loss of water of crystallization, and when heated at 100° C. (212° F.), it is rendered anhydrous. The aqueous solution is neutral to litmus paper. With sodium bitartrate T.S. the concentrated aqueous solution yields a white crystalline precipitate. The color of the precipitate produced by the addition of ferric chloride T.S. to the diluted aqueous solution of the salt is dark blue; that produced by copper sulphate T.S. is reddish-brown; lead acetate T.S. or silver nitrate T.S. causes a white precipitate. No effervescence should be caused by the addition of diluted sulphuric acid to a concentrated solution of the salt (absence of carbonate). The precipitate produced by silver nitrate T.S. in the aqueous solution, acidulated with nitric acid, should be of a white color, without a tinge of red (absence of ferricyanide)." U. S. It acts but slightly, if at all, on turmeric paper. The alkaline reaction, when it exists, is probably owing to the presence of a little potassium hydroxide. When ignited, the insoluble residue amounts to 18.7 per cent. of ferric oxide, resulting from the oxidation of the iron of the salt. It is characterized by striking a deep-blue color with ferric salts,¹ a deep-brown

¹ *Ferri Ferrocyanidum*, U. S. 1870. *Ferri Ferrocyanuretum*, U. S. 1850; *Ferrocyanide of Iron*, *Ferrocyanuret of Iron*, *Pure Prussian Blue*.—"Take of Ferrocyanide of Potassium nine troyounces; Solution of Tersulphate of Iron a pint; Water three pints. Dissolve the Ferrocyanide of Potassium in two pints of the Water, and add the solution gradually to the Solution of Tersulphate of Iron, previously diluted with the remainder of the Water, stirring the mixture during the addition. Then filter the liquid, and wash the precipitate on the filter with boiling water until the washings pass nearly tasteless. Lastly, dry it, and rub it into a powder." U. S. 1870.

In the above process the salt is decomposed by the gradual addition of the solution of potassium ferrocyanide. Three molecules of ferrocyanide and two of ferric sulphate are mutually decomposed, with the result of forming one molecule of Prussian blue, or the 3-4 ferric ferrocyanide, which precipitates, and six molecules of potassium sulphate, which remain in solution, the reaction being:

Preparation for Use in the Arts.—Prussian blue is manufactured on the large scale as follows: A mixture made of equal parts of potassium carbonate (pearlash of commerce) and of animal matter, such as dried blood, hair, the shavings of horn, etc., is calcined at a red heat, in an iron vessel, until it becomes pasty. The mass, when cold, is thrown, by portions at a time, into twelve or fifteen times its weight of water, with which it is stirred for half an hour. The whole is then put upon a linen filter, and the clear solution obtained is precipitated by a mixed solution of two parts of alum and one of ferrous sulphate. An effervescence occurs, due principally to carbon dioxide, and a very abundant precipi-

one with the salts of copper, a white one with those of zinc, the several precipitates formed being ferrocyanides of the respective metals. Heated with eight or ten times its weight of concentrated sulphuric acid, it evolves carbon dioxide. Half an ounce of the salt yields about 250 cubic inches of the gas. (C. Grimm and G. Ramdohr.) When boiled with diluted sulphuric acid, it emits the easily recognized odor of hydrocyanic acid.

Potassium ferrocyanide consists of six groups of the monad radical cyanogen (CN), saturated by four potassium atoms and one atom of the dyad iron. The potassium is more readily displaced than the iron, so that it is considered as the potassium salt of an acid called *hydro-*

ferrocyanic. This acid in the free state would be $\text{H}_4\text{Fe}(\text{CN})_6$. The salt is remarkably pure as it occurs in commerce.

Uses.—Pure potassium ferrocyanide is physiologically very inactive. Thus, Combemale and Dubiquet proved that in doses of twelve grains to the pound of bodily weight it is not poisonous to the lower animals, while Callies, as quoted by Pereira, found the commercial salt slightly poisonous, but the pure salt unproductive of harm in the dose of several ounces. It should be borne in mind that it is the commercial salt which is used medicinally. Westrumb and Hering proved that it passed with rapidity into the blood and urine.

This salt is manufactured on a large scale, chiefly for the use of dyers and calico printers. In pharmacy it is employed to prepare diluted hydrocyanic acid, Prussian blue, and potassium and silver cyanides.

Dose, five to ten grains (0.32 to 0.65 Gm.).

POTASSII HYDROXIDUM. U. S. (Br.)

POTASSIUM HYDROXIDE [Potassium Hydrate, Caustic Potash, Potassa, Pharm. 1890]

(po-tās'sī-i hŷ-drōx'ī-dŭm)

KOH = 55.74

"It should contain not less than 85 percent. of pure anhydrous Potassium Hydroxide, and not more than 2 percent. of other inorganic substances, with the exception of water. It should be kept in well-stoppered bottles made of hard glass." *U. S.* "Potassium hydroxide, KOH, with not more than 10 per cent. of combined water and impurities, prepared by the interaction of potassium carbonate and calcium hydroxide." *Br.*

Potassa Caustica. *Br.*; Kali Purum; Caustic Potassa, Hydrate of Potassa, Potassæ (Potassil) Hydras, Kali Hydricum Fusum, Lapis Causticus Chirurgorum; Potasse caustique, *Fr. Cod.*; Potasse Fondue, Pierre à cautère, *Fr.*; Kali Causticum Fusum, *P. G.*; Kallumhydroxyd, Kallum-Hydrat, Kaustisches Kali, Ätzkali, *G.*; Potassa caustica, *It.*; Hidrato potassico, *Sp.*

"Take of Solution of Potash two pints [Imperial measure]. Boil down the Solution of Potash rapidly in a [clean] silver vessel, until there remains a [clear] fluid of oily consistence, a drop of which when removed on a warm glass rod solidifies on cooling. Pour this into proper moulds, and when it has solidified, and while it is still warm, put it into stoppered bottles." *Br.* 1885. A process for potassium hydroxide is no longer in the *U. S. Pharmacopœia*; that of 1870 is identical with the British (1885).

The solid alkali obtained from these processes is potassium hydroxide, sufficiently pure for medicinal purposes. The solution of the alkali freed from carbonic acid (having been obtained by another formula (see *Liquor Potassii Hydroxidi*), the formation of the present preparation requires merely the evaporation of this solution until nearly the whole of

tate is thrown down of a blackish-brown color. This precipitate is washed, by decantation, by means of a large quantity of water, which is removed every twelve hours. By these washings, which last from twenty to twenty-five days, the precipitate becomes successively greenish brown, bluish, and finally deep blue. When of the latter color, it is collected and allowed to drain upon a cloth, after which it is divided into cubical masses and dried.

A preparation under the name of *Soluble Prussian Blue* has been introduced into use for injecting anatomical preparations by Schroeder van der Kolk, and is said to be much esteemed for this purpose. To obtain it there must be a great excess of the potassium ferrocyanide in concentrated solution. The iron should be in a state of sesquichloride, in the proportion of not more than one-eighth or one-tenth of the ferrocyanide employed. After their mixture, the precipitate is washed with water till it begins to become blue, when it is expressed and dried in the air. On the small scale it may be economically obtained in the following manner. Take solutions of the ferrocyanide containing 217 grammes to the liter of water, and of the sesquichloride containing one part of the solid salt in 10 parts of water. Then, taking equal volumes of the two solutions, add to each one twice its volume of a cold concentrated solution of sodium sulphate, and mix the solutions. Pour on a filter, and treat as directed above. The product dried in the air is perfectly soluble, and admirably adapted for injection. (*J. P. C.*, 4e sér., iv. 238.) For other formulae for soluble Prussian blue, see *Ibid.*, 4e sér., xix. 227.

Properties.—Pure Prussian blue is a tasteless powder, insoluble in water and alcohol, and having a rich deep blue color. It is insoluble in dilute acids, decomposed by fuming nitric acid, and dissolved without decomposition by strong sulphuric acid, forming a white mass of the consistence of paste, from which the Prussian blue may be precipitated unchanged by water. Concentrated hydrochloric acid decomposes it, dissolving ferric oxide, and liberating hydroferrocyanic acid. When boiled with mercuric oxide, it generates mercuric cyanide. (See *Hydragryl Cyanidum*.) By the contact of a red-hot body it takes fire and burns slowly, leaving a residue of ferric oxide. When it is heated in close vessels, water, hydrocyanic acid, and ammonium carbonate are evolved, and iron carbide is left. Its composition has been given above. The Prussian blue of commerce was discovered by accident, in 1710, by Diesbach, a preparer of colors at Berlin. It has the same general properties as the pure substance. It occurs in small rectangular masses, which are heavier than water and have a fracture presenting a bronzed appearance. Besides the constituents of pure Prussian blue, it always contains uncombined ferric oxide, and a portion of alumina, derived from the alum employed in its manufacture, which serves to give it body as a pigment. These substances may be detected by boiling the pigment with diluted hydrochloric acid and precipitating the filtered solution with ammonia. Pure Prussian blue treated in this manner yields no precipitate.

Uses.—Prussian blue has been deemed tonic, febrifuge, and alterative, but is at present very rarely used, and is probably of no medicinal value. It is sometimes employed as an application to ill-conditioned ulcers, mixed with simple ointment in the proportion of a drachm to the ounce. The *dose* is from three to five grains (0.20 to 0.32 Gm.), repeated several times a day, and gradually increased until some effect is produced.

its uncombined water is driven off. The evaporation must be performed in metallic vessels, as those of glass or earthenware are acted on by the alkali, and it should be completed as quickly as possible, in order to abridge the period during which the solution would be liable to absorb carbon dioxide from the atmosphere. When poured out on a metallic plate or dish, the cake, just as it solidifies, may be marked with a knife in the direction in which it is to be divided, and when cold it readily breaks in those directions. A better plan, however, is to run the fused alkali into suitable moulds, as directed in the former U. S. and British formulas. These should be made of silver or iron and have a cylindrical shape, which is the most convenient form of the alkali for surgical use. Green glass bottles with rubber stoppers are best adapted for preserving this preparation, as white flint glass is attacked by the alkali. Potassium hydroxide is now prepared at Niagara Falls, N. Y., by the electrolysis of strong potassium chloride solution. The metal at the cathode acts with water to form potassium hydroxide and free hydrogen, while chlorine is liberated at the anode.

Properties.—It is officially described as in “dry, white flakes, fused masses, or in pencils, hard and brittle, showing a crystalline fracture; odorless, or having a faint odor of lye, and of a very acrid and caustic taste. *Great caution is necessary in tasting and handling it*, as it rapidly destroys organic tissues. Exposed to the air, it readily absorbs carbon dioxide and moisture, and deliquesces. Soluble in about 0.4 part of water at 25° C. (77° F.), and in 2 parts of alcohol; very soluble in boiling water, and in boiling alcohol; slightly soluble in ether. When heated to about 530° C. (986° F.), Potassium Hydroxide melts to a clear, oily liquid, and at a bright red heat is volatilized unchanged. When introduced into a non-luminous flame, it imparts to it a violet color. A solution of Potassium Hydroxide, even when greatly diluted, gives an intensely alkaline reaction with red litmus paper. The aqueous solution (1 in 20) should be perfectly clear and colorless. A concentrated solution of Potassium Hydroxide, after acidulation with hydrochloric acid, yields a bright yellow precipitate with platinum chloride T.S. A concentrated, aqueous solution (1 in 10), when added to an excess of tartaric acid T.S., produces a white, crystalline precipitate, which redissolves when the Potassium Hydroxide is added in excess. An aqueous solution of Potassium Hydroxide (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). On adding an excess of diluted sulphuric acid to 10 Cc. of an aqueous solution of Potassium Hydroxide (1 in 10), no distinct effervescence should occur (limit of *carbonate*). Introduce about 1 Gm. of Potassium Hydroxide into a stoppered weighing-bottle and weigh accurately. Dissolve this in about 50 Cc. of water and titrate

the solution with normal sulphuric acid V.S., using methyl-orange T.S. as indicator. Multiply the number of Cc. of the normal sulphuric acid V.S. consumed, by 5.574, and divide this product by the weight of the Potassium Hydroxide taken; the quotient, which must be not less than 85, represents the percentage of Potassium Hydroxide present.” U. S. “White pencils or cakes, very deliquescent, powerfully alkaline and corrosive. Soluble in half its weight of *water* and twice its weight of *alcohol* (90 per cent.). It affords the reactions characteristic of potassium. Each gramme dissolved in *water* or in *alcohol* (90 per cent.) should leave only a trace of sediment, and should require for neutralization at least 16.1 cubic centimetres of the *volumetric solution of sulphuric acid*. It should yield no characteristic reaction with the tests for lead, copper, or arsenium.” Br. It is important that the requirements of the Pharmacopœia be complied with, and that it should contain 85 per cent. of pure potassium hydroxide and not more than 2 per cent. of other inorganic substances, with the exception of water.

The *white stick caustic potassa* as found in commerce usually contains from 15 to 28 per cent. of water, which seems to be a necessary impurity, for if a certain quantity of water is not present it is impossible to mould the stick. By heating this so as to drive off the water a purified hydroxide in cakes may be obtained. On account of its deliquescent property, and its strong attraction for carbon dioxide, potassium hydroxide requires to be kept in very accurately stoppered bottles. As formerly obtained, from solution of potassium hydroxide derived from an impure carbonate, it contained various impurities, which, however, did not interfere with its medicinal value,—such as potassium chloride and tetroxide, ferric oxide, lime, silica, alumina, potassium sulphate, and a portion of the alkali still in a carbonated state. Official potassium hydroxide may be rendered nearly pure by digestion in alcohol, which takes up only the alkaline hydroxide, evaporating the solution to dryness, and fusing the dry mass obtained. *Potassium hydroxide*, when thus procured, is called *potash by alcohol*. It is generally in flat white pieces, which are dry, hard, brittle, and extremely caustic. Its other properties are similar to those of the impure hydroxide above described. According to H. Wurtz of New York, commercial potash by alcohol usually contains a trace of potassium silicate, which appears to be taken up by the alcohol. The source of this is the potassium carbonate employed, which may be freed from this impurity by evaporating its aqueous solution, in a sheet iron dish, to dryness, and adding, from time to time, lumps of ammonium carbonate. The silicate is thus converted into the carbonate, and on dissolving the residue the silica appears in flakes, which may be separated by filtration. Potassium hydroxide may be distinguished

from the other fixed alkalis (soda and lithia) by its affording, when in solution, a crystalline precipitate (cream of tartar) with an excess of tartaric acid, and a yellow one with platinic chloride. Potassium hydroxide imparts to the flame of burning alcohol in which it is dissolved a reddish tint; sodium hydroxide colors it yellow even in the presence of potassium hydroxide; and thus a method is afforded of detecting an admixture of the latter with the former alkali. According to Bunsen, when the flame is viewed through a glass having a cobalt-blue color, only the color imparted by potassium is seen, the yellow color of the sodium flame being absorbed by the blue glass. (*J. P. C.*, Oct. 1860, p. 319.) Potassium hydroxide, KOH, is composed of one atom of potassium, united with one hydroxyl group, OH.

Uses.—This is the old *causticum commune acerrimum*, or *strongest common caustic*; see also *Potassa cum Calce*.¹ It is a powerful escharotic, quickly destroying the life of the part with which it comes in contact, and extending its action to a considerable depth beneath the surface. In this latter respect it differs from silver nitrate, or lunar caustic, to which it is, therefore, preferred in forming

issues and opening abscesses. The most convenient mode of employing the caustic for the formation of an issue is to apply to the skin a piece of linen spread with adhesive plaster, having a circular opening in its centre corresponding with the intended size of the issue, and then to rub upon the skin, within the opening, a piece of the caustic previously moistened at one end.² The application is to be continued until the life of the part is destroyed, when the caustic should be carefully washed off with a wet sponge or wet tow, or neutralized by vinegar. In forming from it solutions of potassium hydroxide of definite strength, whether for medicinal or for pharmaceutical use, an allowance should be made for the percentage of water it always contains. (See *Liquor Potassii Hydroxidi*.)

POTASSII HYPOPHOSPHIS. U. S.

POTASSIUM HYPOPHOSPHITE

(pō-tās'sī-I hŷ-pō-phōs'phīs)

$\text{KH}_2\text{PO}_2 = 103.39$

"It should contain not less than 98 percent. of pure Potassium Hypophosphite [$\text{PO.H}_2\text{O K}$], and should be kept in well-stoppered bottles. Caution should be observed in dispensing Potassium Hypophosphite, as explosion is liable to occur when it is triturated or heated with nitrates, chlorates, or other oxidizing agents." *U. S.*

Kali Hypophosphorosum, *Hypophosphis Potassicus*, s. *Kalicus*; *Hypophosphite de Potasse*, *Fr.*; *Unterphosphorisaures Kali*, *G.*

This salt is prepared by mixing solutions of calcium hypophosphite and granulated potassium carbonate, in the proportion of 6 ounces of the former dissolved in four pints of water to 5.75 ounces of the latter in half a pint. As a result of double decomposition between the two salts, calcium carbonate and potassium hypophosphite are formed, the former being precipitated, and the latter held in solution. The calcium carbonate is removed by filtration, and the clear solution is evaporated until a pellicle forms, after which it is constantly stirred, with continuance of the heat, until the salt granulates. The heat employed in the evaporation should be kept considerably below 100° C. (212° F.), for fear of explosion. If the salt

¹ *Potassa Cum Calce*. *U. S.* 1890. *Potassa with Lime*.

Pulvis Causticus cum Calce, *Pulvis Causticus Viennensis*; *Vienna Caustic*, *Vienna Paste*; *Caustique (Poudre) de Vienne*, *Fr.*; *Wiener Aetzpulver*, *G.*

"*Potassa, five hundred grammes* [or 17 ounces av., 279 grains]; *Lime, five hundred grammes* [or 17 ounces av., 279 grains], to make one thousand grammes [or 35 ounces av., 120 grains]. Rub them together, in a warm iron mortar, so as to form a powder, and keep it in a well-stoppered bottle." *U. S.* 1890. This preparation is "a grayish-white powder, deliquescent, having a strongly alkaline reaction, and responding to the tests for calcium and potassium. It should be soluble in diluted hydrochloric acid without leaving more than a small residue." *U. S.* 1890. It should not effervesce on the addition of an acid. It is prepared for use by being made up into a paste with a little alcohol. The paste is applied for ten or fifteen minutes to the part to be cauterized, and is conveniently limited in its operation by a piece of adhesive plaster, in the manner explained under *Potassii Hydroxidum*. The former Edinburgh preparation, made by evaporating the solution of potassa to one-third, and adding lime enough to bring it to the state of a firm paste, was often called *causticum commune mitius*, or *milder common caustic*. Potassa with lime is a more manageable caustic than the official potassium hydroxide, on account of the presence of the lime, which renders it milder, slower in its operation, and less deliquescent, and causes it to spread less beyond the part intended to be affected. Filhos has improved this caustic by forming it into sticks. To prepare it thus, the potassium hydroxide is perfectly fused in an iron spoon, and one-third of its weight of quicklime is added in divided portions, the whole being stirred with an iron rod. The fused mass is then run into lead tubes, closed at one end, about three inches long, and from a quarter to half an inch in diameter in the clear. The sticks are kept, still enclosed in the lead tubes with the open end downward, in thick glass tubes, containing some powdered quicklime, and closed with a cork, between which and the stick some cotton is put to steady the caustic. When employed, as much of the caustic is uncovered at the end, by scraping off the lead, as it is proposed to use. This form of caustic is particularly recommended for cauterizing the neck of the uterus. M. E. Robiquet modified the caustic, by fusing the potassium hydroxide and lime at a higher heat, running the fused mass into iron moulds, and quickly coating the sticks, when cold, with melted gutta-percha. The higher heat employed renders the caustic harder and more homogeneous.

² At the suggestion of Maunoury of Chartres, M. E. Robiquet has prepared a paste consisting of gutta-percha and potassium hydroxide, which offers many advantages of manipulation, in the application of the latter substance. It is prepared by simply melting together equal weights of the two substances. The resulting paste can be moulded into any form that may be thought desirable, either of cylinders, plates, or lozenges, and retains its form indefinitely, even when introduced into cavities. All that is necessary, before applying it, is to dip it into alcohol for a few seconds. The resulting eschars are very precise in their form. (*J. P. C.*, xxx. 275.)

be required pure, it should be dissolved in the granulated state, in official alcohol, and the solution evaporated to a syrupy consistence and then set aside to crystallize. The calcium hypophosphite may be prepared by a formula given under the head of *Calcii Hypophosphis*.

Properties.—Potassium hypophosphite, according to the U. S. Pharmacopœia, is in "white, opaque, hexagonal plates, or crystalline masses, or a granular powder; odorless, and having a pungent, saline taste; very deliquescent. Soluble in about 0.5 part of water, and in 7 parts of alcohol at 25° C. (77° F.); in 0.3 part of boiling water, and in 3.6 parts of boiling alcohol; insoluble in ether. When heated in a dry test-tube, the salt at first loses moisture, and then evolves spontaneously inflammable hydrogen phosphide gas, which burns with a bright yellow flame. The aqueous solution (1 in 20) is neutral or slightly alkaline to litmus paper, and yields, with sodium bitartrate T.S., a white, crystalline precipitate. The diluted aqueous solution, slightly acidulated with diluted sulphuric acid, yields, with silver nitrate T.S., a white precipitate, which rapidly turns brown or black, owing to the separation of metallic silver. On gently heating an aqueous solution of Potassium Hypophosphite with copper sulphate T.S., a reddish-brown precipitate is formed. When the aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, is added, drop by drop, to an excess of mercuric chloride T.S., a white precipitate of mercurous chloride is at first formed. On further addition of an excess of the Potassium Hypophosphite solution, the precipitate becomes gray from reduction to metallic mercury. An aqueous solution of the salt (1 in 20) should not effervesce upon the addition of an acid (absence of carbonate). An aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If 5 Cc. of an aqueous solution of Potassium Hypophosphite (1 in 10) be measured into a beaker containing 3 Cc. of nitric acid diluted with about 10 Cc. of water, and the mixture be evaporated to dryness on a water-bath, the residue should not respond to the Modified Gutzeit's Test for *arsenic* (see PART III, Test No. 17)." U. S.

Uses.—This salt, and several other *hypophosphites*, as those of calcium, sodium, ammonium, etc., were brought into notice a few years since, in consequence of their supposed efficiency in the introduction of phosphorus into the system in cases in which this element might be thought to be deficient. Upon this principle they were recommended by Churchill of Paris, in the treatment of *phthisis*, and came into extensive employment, but experience has hardly confirmed the first favorable impression of their usefulness in this complaint. There seem, however, to be good grounds for their application to diseases attended with deficiency of nerve power from debility of the brain, and in

certain *scrofulous affections* of children, especially those connected with a disordered condition of the bones.

Dose, ten to thirty grains (0.65 to 2.0 Gm.).

POTASSII IODIDUM. U. S., Br.

POTASSIUM IODIDE

(pō-tās'sī-i ī-ōd'ī-dūm)

KI = 164.76

"It should contain not less than 99 percent. of pure Potassium Iodide, and should be kept in well-stoppered bottles." U. S. "Potassium Iodide, KI, may be prepared in the same manner as Potassium Bromide, iodine being used in place of bromine." Br.

Iodide of Potassium; Potassii Hydriodas; Kali Hydriodicum, Ioduretum Potassium, s. Calcium; Iodure de Potassium, Fr. Cod.; Kalium Jodatam, P. G.; Kaliumjodid, Jodkallium, G.; Joduro di potassio, It.; Yoduro potassico, Sp.

No process is given in the U. S. or Br. Pharmacopœias. That of the U. S. P. 1870 did not differ essentially from the British 1885.¹

An aqueous solution of potassium hydroxide is treated with iodine in slight excess. The result of thus saturating potassium hydroxide with iodine is the formation of two salts, potassium iodide and iodate. Six atoms of iodine react with six molecules of potassium hydroxide, and there are formed five molecules of potassium iodide and one of potassium iodate,

By evaporating the solution to dryness the mixed salts are obtained, and, if the dry mass be exposed to a red heat, the iodate will be converted into iodide, thus removing this impurity from the iodide. In the formula the mixed salts, towards the close of their evaporation to dryness, are directed to be mixed with powdered charcoal, according to the plan of

¹ "Take of Solution of Potash one gallon [Imperial measure], Iodine twenty-one ounces [avoirdupois], or a sufficiency; Wood Charcoal, in fine powder, three ounces [av.]. Boiling Distilled Water a sufficiency. Put the Solution of Potash into a glass or porcelain vessel, and add the Iodine in small quantities at a time, with constant agitation, until the solution acquires a permanent brown tint. Evaporate the whole to dryness in a porcelain dish, pulverize the residue, and mix this intimately with the Charcoal. Throw the mixture, in small quantities at a time, into a red-hot iron crucible, and, when the whole has been brought to a state of fusion, remove the crucible from the fire and pour out its contents. When the fused mass has cooled, dissolve it in two pints [Imp. meas.] of boiling distilled water, filter through paper, wash the filter with a little boiling distilled water, unite the liquids, and evaporate the whole till a film forms on the surface. Set it aside to cool and crystallize. Drain the crystals, and dry them quickly in a warm place. More crystals may be obtained by evaporating the mother-liquor and cooling. The salt should be kept in a stoppered bottle." Br. 1885.

Scanlon, which facilitates the deoxidation of the iodate. This being accomplished by a dull red heat, the potassium iodide is dissolved out of the mass, and the solution is set aside to crystallize.

In the old Edinburgh and Dublin processes the first step was to form ferrous iodide in solution, precisely as is done in the formula for that compound, and the second to decompose it by potassium carbonate, which gave rise to potassium iodide in solution, and a precipitate of ferrous carbonate. The solution of potassium iodide was separated by filtration and washing from the precipitated carbonate, and evaporated to dryness. The dry salt was then freed from iron and other impurities by solution in boiling water or alcohol, filtration, and crystallization. An improvement on this process is to add enough iodine to the ferrous iodide solution first formed to produce ferrous-ferrie iodide, $\text{FeI}_2(2\text{FeI}_2 + \text{FeI}_2)$. This solution is now treated with an equivalent quantity of potassium carbonate and boiled when ferrous-ferrie oxide precipitates, carbon dioxide escapes, and all the iodine goes into solution as iodide, the reaction being:

According to the method of E. Sonstadt, potassium iodide is prepared directly from the mother liquors of kelp by converting the alkaline iodides into iodates by means of chlorine or potassium permanganate, precipitating the iodic acid by a soluble barium salt, heating the precipitate with solution of potassium sulphate, evaporating the resulting potassium iodate solution to dryness, and crystallizing from its solution the potassium iodide thus obtained. (*Chem. News*, xxvi. 182.) Or, these mother liquors are evaporated to dryness, the mass gently roasted to oxidize sulphides, and then extracted with water, evaporated again to dryness and extracted with alcohol, whereby sodium and potassium iodide go into solution. This is treated with potassium carbonate to change the sodium iodide into potassium iodide, and a stream of CO_2 led through to precipitate the sodium bicarbonate. The remaining solution contains potassium iodide with a little sodium bicarbonate. (Flückiger, *Pharm. Chem.*, 2d ed., 1888, p. 341.) Large quantities are now manufactured from the cuprous iodide coming from the South American sodium nitrate works. The cuprous iodide is suspended in water acidified with hydrochloric acid, and a stream of hydrogen sulphide gas led in, whereby hydrogen iodide enters into solution. This solution is filtered, neutralized with potassium carbonate, and evaporated to crystallization.

Properties.—Potassium iodide, sometimes incorrectly called *hydriodate of potassa*, is in "colorless, transparent, translucent, or opaque white, cubical crystals, or a white, granular powder, having a peculiar, faint, iodine-like odor, and a pungent, saline, afterwards bitter taste. Permanent in dry air, and but slightly

deliquescent in moist air. Soluble in 0.7 part of water, and in about 12 parts of alcohol at 25°C . (77°F .); in 0.5 part of boiling water, in 6 parts of boiling alcohol; also soluble in 2.5 parts of glycerin. When heated, the salt decrepitates. At a low red heat it fuses, and at a bright red heat it is volatilized without decomposition. Its aqueous solution is neutral, or has a slightly alkaline reaction upon litmus paper. If 1 Gm. of the salt be dissolved in 10 Cc. of water, and 0.1 Cc. of tenth-normal sulphuric acid V.S. be added, no color should be produced by the subsequent addition of a drop of phenolphthalein T.S., even after heating (limit of *alkali*). An aqueous solution of Potassium Iodide (1 in 20) yields a white, crystalline precipitate with sodium bitartrate T.S. If to 5 Cc. of the aqueous solution of the salt (1 in 20) 1 Cc. of chlorine water be added, iodine will be liberated, and impart to the solution a light reddish-brown color. On agitating the mixture with a few drops of chloroform, the latter will acquire a violet color." *U. S.* According to T. & H. Smith of Edinburgh, it is not at all deliquescent when perfectly pure. It generally crystallizes in cubes. If solution of potassium iodide be mixed with solution of starch, and a minute quantity of solution of chlorine be added, a blue color will be produced, the chlorine combining with the potassium liberating the iodine, which forms a blue compound with starch.

Its solution is quickly decomposed by the addition of a few drops of sulphuric acid, hydriodic acid being generated, which speedily undergoes decomposition, with evolution of iodine, and, if starch be added after the lapse of a few minutes, a blue color will be produced. The starch test will not give the characteristic blue color immediately, if added simultaneously with the acid, unless the potassium iodide contains potassium iodate, which impurity causes an immediate liberation of iodine. The blue color being produced by the starch and acid, if simultaneously added, is, therefore, a sign of impurity. A very delicate test for potassium iodide and other soluble iodides is that of Grange. It consists in pouring a little of the liquid to be examined into a test tube, adding a few drops of solution of starch, and passing through the mixture a few bubbles of fuming nitrous acid. The liquid immediately assumes a pale rose color, inclining to violet, if containing 1-200,000th of its weight of the iodide, and a bright blue color if 1-100,000th is present. (See page 665.) When tartaric acid is freely added to a strong solution of the iodide, it occasions a white crystalline precipitate, and the supernatant liquid, if mixed with starch, becomes first purple, and finally blue. Platinic chloride colors its solution reddish-brown, without causing a precipitate; barium chloride but slightly affects it, and ferrous sulphate occasions no change. The non-action of the last test shows the absence of potassium carbonate.

The aqueous solution is capable of taking up a large quantity of iodine, forming a liquid of a deep brown color.

Payen has noticed a curious effect produced by potassium iodide. In saturated solution, this salt causes in starch added to it an enlargement of its granules to twenty-five or thirty times their original volume, dissolving the inferior substance of the granules, and enormously distending the exterior layer. Potassium bromide produces the same effect, but the alkaline chlorides cause neither the enlargement referred to, nor a solution of the amylaceous substance, and if the saturated solution of the iodide be diluted with three and a half volumes of water or more, it is inert in reference to starch in the cold. (*J. P. C.*, 4e sér., ii. 373.) Ferrières found that ether added to a solution of potassium iodide decomposes it, but it has been shown by the researches of de Vrij and of Magnes-Lahens that this does not happen with pure ether, but is due to the acetic acid which is developed by sunlight in ether. (*J. P. C.*, 4e sér., xvi. 107, 468; xvii. 116.)

Tests.—Exposed to a dull red heat, potassium iodide fuses, and on cooling concretes into a crystalline pearly mass, without loss of weight; but at a full red heat it is slowly volatilized without decomposition. The most usual impurities contained in this salt are potassium and sodium chlorides, potassium bromide, and potassium carbonate and iodate. Potassium iodide, to conform to the U. S. P. (8th Rev.), must contain 99 per cent. of the pure salt. The official tests are as follows: "No residue should be left when 1 Gm. of the salt is dissolved in 2 Cc. of diluted alcohol of specific gravity 0.928 (absence of *less soluble salts*). If to 0.5 Gm. of the salt, dissolved in 10 Cc. of distilled water, which has previously been boiled and cooled in a small flask, 2 drops of diluted sulphuric acid (free from sulphurous and nitrous acids) be added, no distinct yellow color should appear within half a minute (limit of *iodate*). An aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If to 1 Gm. of Potassium Iodide contained in a test-tube of about 40 Cc. capacity, 5 Cc. of water, 5 Cc. of potassium hydroxide T.S., and about 0.2 Gm. of aluminum wire be added, and if, in the upper portion of the test-tube, a pledget of purified cotton be inserted, and over the mouth there be placed a piece of moistened red litmus paper, then, if the tube be heated upon a water-bath for fifteen minutes, no blue coloration of the paper should be discernible (limit of *nitrates* and *nitrites*). Ten Cc. of the aqueous solution of the salt (1 in 20), when acidulated with hydrochloric acid, should not be rendered turbid by the addition of 1 Cc. of potassium sulphate T.S. (absence of *barium*). If 5 Cc. of the aqueous solution be gently heated with one drop of ferrous sulphate T.S. and 0.5 Cc. of potassium

hydroxide T.S., no blue color should appear after acidulating the mixture with hydrochloric acid (absence of *cyanide*). If 0.2 Gm. of Potassium Iodide be dissolved in 2 Cc. of ammonia water (10 percent.), and 13 Cc. of tenth-normal silver nitrate V.S. be added, then, after thoroughly agitating and filtering, the filtrate, upon acidifying with nitric acid, should not become more than slightly turbid nor should any darkening appear within ten minutes (limit of *chlorides* and *bromides* and absence of *thiosulphate*). If 0.5 Gm. of the well-dried salt be dissolved in 10 Cc. of distilled water, and about 3 drops of potassium chromate T.S. be added, it should require not more than 30.8 Cc. nor less than 30 Cc. of tenth-normal silver nitrate V.S. to produce a permanent red color (corresponding to at least 99 percent. of pure Potassium Iodide)." U. S. "Each gramme should require for complete precipitation not less than 59.5 and not more than 61.9 cubic centimetres of the volumetric solution of silver nitrate." Br.

The low price of potassium bromide, compared with that of the iodide, has caused the former to be used for the adulteration of the latter. When potassium bromide is sold for the iodide, the fraud may be detected by the fact that the addition of sulphuric acid produces copious reddish fumes, instead of the purple ones arising from the iodide. A very delicate test for bromide in iodide is based upon the different actions of iodide and bromide with lead dioxide. This reagent will liberate iodine from iodide on boiling, but will not decompose any bromide by boiling. Therefore, after the suspected sample has been boiled with the lead dioxide until all the iodine is driven off, and then filtered, the filtrate may be treated with fresh dioxide and a little acetic acid, when any bromine present is decomposed, and the free bromine will color carbon disulphide or answer other tests. (Flückiger, *Pharm. Chem.*, 2d ed., 1888, p. 350.) Lepage determined the amount of the bromide as follows. Dissolve one gramme of corrosive sublimate in twenty cubic centimeters of water; also one gramme of the suspected iodide in thirty grammes of pure water. Add by means of a burette the former fluid to the latter until it just ceases to cause a turbidity. If the iodide is pure, at least 16 Cc. of the mercurial solution are required; if impure, the remaining solution will exceed the volume of 4 Cc. in proportion as the potassium iodide has been replaced by bromide. For this test it is necessary that the iodide be free from chloride, carbonate, and iodate. (*A. J. P.*, xlv. 167.) In order to detect bromine, Personne first precipitated from an aqueous solution of the suspected iodide the whole of the iodine as cuprous iodide, by successively adding, in excess, a solution of copper sulphate and aqueous sulphurous acid, and then treats the filtered liquid with ether and chlorine water, the whole being shaken together and left at rest. If bromine be present, the ether which rises to the surface

will be tinged of a reddish-yellow color. Fresenius's test of gold chloride is, according to J. H. Bill, of the U. S. Army, very delicate. The iodine having been separated by palladium, and the excess of palladium by hydrogen sulphide, the solution supposed to contain bromine, if treated first with a drop of hydrochloric acid, and then with a drop of solution of gold chloride, will, if bromine be present, exhibit a decided yellowness, which will appear more obviously if the solution be compared with pure water or a weak solution of a chloride. (See *A. J. P.*, 1868, 272.) Potassium carbonate may be discovered by lime water, which causes a milkiness (calcium carbonate), and by tincture of iodine, the color of which is destroyed. The iodate may be detected by adding a solution of tartaric acid to a solution of the suspected iodide. Potassium bitartrate will be precipitated, and, if the iodide be pure, a yellow color will soon be developed by the action of the air on the liberated hydriodic acid; but if any iodate be present the test will give rise to both iodic and hydriodic acids, which, by their mutual action, will instantly develop iodine.

William Copney has pointed out an excellent test for detecting potassium carbonate and iodate, in the use of ferrous iodide, in the form of syrup of ferrous iodide, recently prepared. (See *Syrupus Ferri Iodidi*.) A drop of the syrup is added to a solution of the suspected potassium iodide. A bluish precipitate indicates the carbonate; a red one, the iodate; and a blue precipitate, followed by a red one, both impurities. An adulteration by the carbonate under 10 per cent. does not alter the crystalline appearance of the iodide, but gives it an increased tendency to deliquesce. When it is greater it renders the salt granular and highly deliquescent. As potassium iodide is soluble in rectified spirit, anything left undissolved by that solvent is impurity. (*A. J. P.*, xxvi. 293.) A seemingly better method is that of Personne, founded upon the fact that when mercuric chloride is added to a solution of the iodide in just sufficient amount to form potassio-mercuric iodide the solution remains clear, but on the further addition of the minutest quantity of the chloride a persistent reddish or rose-colored precipitate is formed. He prepares the titrating solution by dissolving 13.55 grammes of mercuric chloride and 8 to 10 grammes of common salt in 200 to 250 grammes of distilled water, and then adding sufficient distilled water to make the whole measure one liter; 10 cubic centimeters of this correspond to 0.1355 of the chloride. Of the iodide to be tested 3.32 grammes are dissolved in sufficient water to make exactly 100 cubic centimeters. The titration is performed by putting 10 cubic centimeters of this in a beaker glass, and adding from a burette, drop by drop, the mercurial liquid, keeping the beaker in a constant agitation by means of the gyratory movement with the hand. When the red color

appears the titration is complete. If the iodide be pure, 10 cubic centimeters of the mercurial solution will have been used; if only 8 Cc. have been used, it is known that the iodide contains only 80 per cent. of the pure salt; 9 Cc. indicate 90 per cent.; 7 Cc., 70 per cent., and so on. The presence of potassium bromide, chloride, or carbonate is said not to interfere with this test. (*J. P. C.*, Janv. 1875, p. 5.) Potassium iodide contains no water of crystallization.

According to Payen, a saturated solution of potassium iodide, which will evince signs of decomposition by becoming orange-yellow, in the presence of atmospheric air, on the addition of small quantities of acetic, nitric, oxalic, and probably many other acids, remains unaffected by these additions if atmospheric air be excluded. It was first pointed out by Loew (*A. J. P.*, xlii. 80), and afterwards confirmed by Vidau in an elaborate series of experiments, that iodine is liberated from a solution of potassium iodide by direct sunlight; the more concentrated the solution the more energetic is the action. (*J. P. C.*, 4e sér., xx. 351.)

Potassium iodide is incompatible with a few alkaloids, calomel, mercurous and mercuric oxides, turpeth mineral, white precipitate, blue mass, and metallic mercury. Melsens observed that potassium iodide given in connection with the insoluble preparations of mercury rendered them soluble and much more active. (See *A. J. P.*, xxvi. 222.) With nitrous ether potassium iodide reacts, yielding, among other products, ethyl iodide and a little ordinary ether. (Jun-cadella, *C. R. A. S.*, Fév. 1859, p. 345.) At ordinary temperatures potassium iodide is slowly decomposed, with evolution of iodine, by ammonium nitrate or boric acid, and at high temperatures, in a glass test tube, with escape of violet vapors, not only by the two substances just named, but also by ammonium sulphate, oxalate, carbonate, and chloride, sodium sulphate, phosphate, nitrate, and borate, potassium and magnesium sulphates, calcium nitrate, sodium, potassium, and calcium chlorides, and silicic acid. (Ubal dini, *J. P. C.*, Oct. 1859, p. 292.) Melsens has noticed another very important fact in relation to the operation of potassium iodide. When this salt and potassium chlorate are mixed in solution, no change takes place at ordinary temperatures; but if a certain amount of a mineral acid be added to the solution of the mixed salts, a reaction occurs, attended with the escape of iodine, and evidences are presented of the existence of iodic acid in the solution. Now, Melsens has ascertained by experiments on dogs that neither of these salts, if given separately and at different times, produces an evil effect, while if given together, so as to be in the system at the same time, they act as a poison, and may cause death in a few days. Seven grammes (108 grains) of a mixture of potassium iodide and potassium chlorate, in equivalent proportions, given daily to a dog of medium size,

uniformly proved fatal in less than a month, and often as early as the fifth day. Melsens ascribed the result to the production of potassium iodate, which he has shown to be a poisonous salt. (*A. J. P.*, Nov. 1866, p. 521; from *Bull. Soc. Chim.*) With certain alkaloids potassium iodide is incompatible, and fatal results have been caused by the strychnine iodide crystallizing out of a prescription, so that the whole of it was taken at a single dose.

Uses.—The general therapeutic properties of the preparations of iodine, of which potassium iodide is the most important, have been given under the head of Iodine. By most practitioners the preparation under notice is preferred for producing the constitutional effects of iodine. When it is administered in large repeated doses it produces evidences of systemic affection, known as *iodism*. The most usual indication of its constitutional action is a pain over the brow, with coryza; in some cases a mild pyralism, with fetor of the breath and slight swelling of the gums, is produced. In a number of cases it causes an eruption, sometimes simply of macula, but usually of acne. In unusual conditions of the system these skin affections may become very severe and ulcerations result; thus, John O'Reilly of New York, reports several cases in which, after the use of this iodide, spots like purpura were produced, invading first the face and then the trunk and extremities. These became bullæ, sometimes an inch in diameter, filled with a purple liquid, and finally sphacelated spots ending in ulcers. Great constitutional disturbance coexisted, with swollen tongue, fetor, and salivation. Bumstead (*Am. J. M. S.*, lxii. 101) and H. C. Wood have seen similar cases. When it is given in a too concentrated form, as when compressed pills are prescribed, its local irritant properties assert themselves, and severe gastro-intestinal irritation or inflammation may result.

The amount of iodine which the individual will bear varies, but in those who have not been gradually accustomed to its use the power of resisting very large doses is strong evidence of a syphilitic infection. In *periosteal nodes*, *specific rheumatism*, *diseases of the nervous system* or *large viscera*, and in other forms of advanced *secondary* or *tertiary syphilis*, potassium iodide acts as a specific, but must be given in very large doses and continuously for months or even years. It is when the symptoms are not very active, or when evidences of cachexia forbid mercurials, that it is especially indicated. In 1843, Guillot and Melsens gave potassium iodide with advantage in doses of from a drachm to a drachm and a half daily, in *mercurial tremors* and *lead poisoning*. In a memoir published in 1849, Melsens gives a full account of his experiments with it as a remedy for the affections caused by mercury and lead. He effected a number of cures of *mercurial tremors* and *lead palsy*, and during the progress of the cure these metals were found in the urine. The value of potassium

iodide in various chronic metallic poisonings is now established, and there can be little doubt as to the correctness of the theory of Melsens, namely, that potassium iodide forms with insoluble metallic compounds in the tissues soluble double salts, which are taken up by the blood and eliminated by the emunctories.¹ Potassium iodide sometimes produces pyralism, but this effect, when directly caused by the iodide, is never severe. Occasionally, however, during the taking of the iodide, furious pyralism will occur, which is the result, as was first shown by Melsens, of the liberation from the tissues of mercury which had been previously taken, and which was enabled by being dissolved to produce constitutional effects. As this pyralism may come on in persons who have not taken mercury for months, or perhaps for years, it would appear that that metal can long lie fixed and insoluble in the system, and finally, when liberated, produce serious constitutional symptoms. A prolonged mercurial treatment should always be followed by a course with potassium iodide. G. W. Balfour of Edinburgh, published several cases of *aneurism of the aorta* in which potassium iodide was given in the dose of thirty grains twice or thrice daily with apparently great advantage, the symptoms of the disease having not only been greatly relieved, but in some instances having entirely disappeared. (*Ed. M. J.*, July, 1868, p. 33; also April, 1871, p. 935.) The results probably were due to the aneurisms being of syphilitic origin. For the *softening of inflammatory deposits*, and for the *removal of exudations* not of syphilitic nature, potassium iodide is one of the most reliable remedies that we have. Hence it is much used in *chronic pleurisies*. In *chronic disease of the pulmonic parenchyma*, especially when tubercular, the exhibition of potassium iodide frequently has a pronounced effect in hastening softening and ulceration. Potassium iodide has been used internally by A. Beaufort with much supposed advantage for a local effect. Being largely secreted with the tears, and to a certain extent with the uterine fluids, he gives it with a view to its effects on the passages with which it thus comes in contact. In this way he explains the very good effects he has experienced from it in *chronic inflammation of the lachrymal passages*, and in *chronic metritis* with copious leucorrhœa. (*B. F. M. R.*, Oct. 1868, p. 517.)

The dose varies enormously; iodism may be produced by ten grains a day, and an ounce a day may in other cases be taken without distinct effect. In serious syphilitic cases a drachm a day may be given and rapidly increased to half an ounce (15.5 Gm.) unless iodism or the therapeutic effect is produced. When it is given in large amounts, care should be exercised to secure free dilution, and the best method of

¹ See the Memoir of Melsens, translated by Budd of Bristol, England, in the *B. F. M. R.*, Am. ed., for Jan. 1853, p. 157; also a paper by J. W. Corson, in the *N. Y. Journ. of Med.* for Sept. 1853.

administration is in solution in milk. The compound syrup of sarsaparilla will in a measure disguise the taste.

Potassium iodide passes quickly into the urine, in which it may be detected by first adding to the cold secretion a portion of starch, and then a few drops of nitric acid, when a blue color will be produced. It has been detected in six minutes after having been swallowed. According to Schottin, it passes slowly into the sweat. Taken in half-drachm doses daily, it did not appear in that secretion until five days had elapsed.

Potassium iodide is employed as an external application in the form of ointment, either alone or mixed with iodine. (See *Unguentum Potassii Iodidi* and *Unguentum Iodi*.)

Dose, five to twenty grains (0.32 to 1.3 Gm.); in special cases much larger doses may be exhibited.

Potassium nitrate or nitre, is both a natural and an artificial product. It occurs in many countries, existing in the soil, on which it forms a saline efflorescence, in the fissures of calcareous rocks, and in caves. It has been found in different parts of Europe, in Egypt, and in Chili, but the country in which it has been largely produced is India. In the United States it is found, for the most part, in caverns situated in limestone rock, called saltpetre caves, where it is associated with calcium nitrate. The earths contained in them are lixiviated, and yield, according to their richness, from one to ten pounds of crude potassium nitrate to the bushel. These caves are particularly numerous in Kentucky, and furnished a large proportion of the potassium nitrate consumed in the United States during the last war with England. According to E. S. Wayne of Cin-

cinnati, nitre earth exists near Nashville, Tenn., which yields 15 per cent. of potassium nitrate, and is said to be sufficiently abundant to supply the demand of the United States. In Bradford County, Pa., a solid, uncrystalline deposit of very pure potassium nitrate was found in a sandstone rock. (W. H. Ellet.) "A mountain" of the salt is said to have been discovered by Harrison among the Rocky Mountains, "six miles N.E. of Crystal Peak." (*A. J. P.*, 1866, p. 87.) Potassium nitrate exists also in the vegetable kingdom, having been found in tobacco, borage, bugloss, parietaria, hemlock, and the sunflower. The artificial sources are certain mixtures of animal and vegetable substances with wood ashes and calcareous matter, called nitre-beds, and certain materials impregnated with saltpetre, consisting principally of plaster rubbish, derived from the demolition of old buildings. The ashes of tobacco stems, consisting almost exclusively of potassium carbonate and chloride, have been proposed by Commaille as an artificial source of potassium nitrate by adding them to the ordinary nitre-beds. (*J. P. C.*, Fév. 1856.)

Preparation from its Natural Sources.—In India the saline earth, which contains about seven parts of potassium nitrate in a thousand, is lixiviated in large mud filters lined with stiff clay, and furnished with false bottoms of bamboo, covered with grass mats, on which wood ashes are laid. The filters being then filled with the saline earth, water is added, and the solution filters through the wood ashes, with the effect of converting the calcium nitrate present, amounting to nearly 1 per cent., into potassium nitrate. The solution obtained is evaporated in earthen pots, filtered, and set aside to crystallize. The impure potassium nitrate thus obtained contains from 45 to 70 per cent. of the pure salt. It is redissolved and crystallized, and thrown into commerce under the name of crude saltpetre. Besides the nitre obtained in India by the filtration of the soil deposited during the overflow of the Ganges, it appears, from the report of J. W. Palmer, that much of the crude salt is procured, in the northwestern provinces of Hindostan, from the saline incrustations formed in and around the mud walls surrounding the dwellings of the natives. The scrapings from these sources are lixiviated, and the impure solution allowed to evaporate in shallow pans exposed to the sun. The impure nitre extracted from the earthy matters crystallizes out, while from 1 to 9 per cent. of sodium chloride remains in the mother liquor, and is recovered by evaporation. (*A. J. P.*, 1868, 436.) *Juar*, a plant used in India as fodder, contains in its stems during dry seasons a large quantity of potassium nitrate (17 per cent.); when in this condition it is poisonous to animals. (*P. J.*, 1896, 380.)

Within recent years potassium nitrate has been most largely manufactured from the native potassium chloride of Stassfurt and the native

sodium nitrate of Chili, two cheap and abundant crude materials, which by their reaction yield potassium nitrate. For this purpose equal molecular quantities of the two salts are dissolved in water with the aid of heat until the specific gravity of the liquor reaches 1.5. The resulting sodium chloride, being less soluble in hot water, is precipitated, and the solution on cooling and agitation deposits the saltpetre as a fine powder. This so-called "conversion saltpetre," as manufactured by Vorster & Grüneberg of Kalk, Germany, and exhibited at the Chicago Exposition, is said to be 99.9 per cent. pure nitrate.

Artificial Preparation.—The plan of making saltpetre in artificial nitre beds is principally practised in Germany, while the method of obtaining it from old plaster rubbish is followed in France. *Artificial nitre beds* are formed of animal and vegetable remains, together with ashes and calcareous earth, which are mixed up with a portion of loose soil and placed under sheds, to shelter the mixture from the rain, while the sides are left open, to admit the free access of air. The mixture is disposed in little ranges or heaps, which are frequently turned over with a spade, and sprinkled with urine, as a substance containing a large quantity of nitrogen. At the end of two or three years the nitrogen is converted into nitric acid, and this, by reacting with the potassium compounds existing in the vegetable remains, forms nitre. When the contents of the bed contain about four ounces of the salt for every cubic foot of the materials, they are deemed fit to be lixiviated. The lixiviation is performed with boiling water, which is repeatedly thrown upon fresh portions of the mass, until the solution obtained is sufficiently strong. The lixivium is of a brown color, and contains chiefly potassium nitrate, but at the same time more or less of calcium and magnesium nitrates and of sodium chloride. The earthy nitrates are then decomposed by a solution from wood ashes, the potassium carbonate of which converts them into nitre and precipitates the earths. The solution being further evaporated, the common salt rises to the surface as a scum, and is removed. The solution is then allowed to cool, and the nitrate crystallizes in dirty-white crystals, called crude nitre. Calcium nitrate may be converted into nitre by adding it to a solution of potassium sulphate. Calcium sulphate is precipitated, and potassium nitrate remains in solution.

Theory of Nitrification.—The continuous formation of nitre in nitre earths and in artificial nitre beds result from the oxidation of the nitrogen of ammonia, thus generating nitric acid, the formation of which is facilitated by the presence of alkaline and earthy bases, with which the acid unites, but in reality depends upon the presence of nitrifying micro-organisms (*Bacillus nitrificans*), so that nitrification is not strictly an oxidation process, as was at one time supposed. The ammonia is derived, for

the most part, from the organic remains in the nitre earths, and from the animal matter which is an essential ingredient in the artificial mixtures. According to Schoenbein, whose statement has been confirmed by Goppelsröder, the formation of the nitric acid is always preceded by that of nitrous acid.

Purification.—Potassium nitrate, as first obtained, either from natural or from artificial sources, is called in commerce crude saltpetre, and requires to be purified before it can be used in medicine or in most of the arts. The process, which is founded principally on the fact that nitre is more soluble than common salt in hot water, is conducted in France as follows: Thirty parts of saltpetre are boiled with six parts of water, and the portion which remains undissolved or is deposited, consisting of common salt, is carefully removed. As the ebullition proceeds, a little water is added from time to time, to hold the nitre in solution. When common salt ceases to be separated, the solution is clarified with glue, and more water is added, at intervals, until the whole, including that previously added, amounts to ten parts. The clear solution is now transferred to large, shallow copper coolers, where it is agitated with wooden instruments to hasten the cooling and to cause the nitre to crystallize in small grains. The purification is completed by washing the salt with water, or a saturated solution of nitre, in a kind of wooden hopper with holes in the bottom stopped with pegs. The liquid employed is allowed to remain in contact with the nitre for several hours, after which it is permitted to drain off by taking out the pegs. The salt is now dried, and takes the name of purified nitre.

In Sweden the process of purification is conducted in a different manner. The solution of the crude nitre is boiled until a saline crust (sodium chloride) forms on its surface, and until it is so far concentrated that a small portion of it crystallizes upon cooling. The crust being removed, the solution is filtered, and diluted with 1-48th of water, with a view to retain in solution the common salt, which, being somewhat less soluble in cold than in boiling water, would otherwise be in part precipitated on refrigeration. This solution is now allowed to cool, and, at the moment the crystals begin to form, is stirred constantly, to cause the salt to crystallize in small grains. The granular salt is then washed after the French method, as before described, dried, and, being fused, is cast in sheet iron moulds so as to form masses, each weighing from ten to twenty pounds. The preparation of nitre in this manner by fusion is, according to Berzelius, attended with several advantages, such as occupying less space, losing nothing by waste in transportation, and presenting, in this state, an obvious index of its quality. This index is the character of its fracture. When the salt is perfectly pure, the fracture is radiated, the radii being generally large. The presence

of 1-80th of sodium chloride renders the radii smaller; that of 1-40th, or of a larger quantity, produces a zone in the substance of the mass devoid of the radiated structure, or causes this structure to disappear entirely. On the other hand, the melting of the salt has the disadvantage of converting it in part into nitrite if the heat be too high, and of rendering it difficult to pulverize.

Commercial History.—Nitre is sometimes received in this country from Calcutta packed in grass-cloth bags containing from one hundred and fifty to one hundred and seventy-five pounds. Its quality varies considerably. That which comes in dirty-yellow crystals is called *crude saltpetre*, while the finer lots, in small comparatively clear crystals, approaching to white, are called *East India refined*. Very little crude saltpetre is at present obtained from native sources in the United States. The *refined saltpetre* is almost exclusively prepared by our own chemists. The importations of crude potassium nitrate are at present less than one-fortieth of the amount of crude sodium nitrate imported. The amount for the year 1903 was 11,700,415 lbs., and for 1904, 13,518, 301 lbs. For an account of what is incorrectly called *South American saltpetre*, see *Sodii Nitras*.

Properties.—Potassium nitrate occurs as "colorless, transparent, six-sided, rhombic prisms, or a white crystalline powder; odorless, and having a cooling, saline and pungent taste. Slightly hygroscopic in moist air. Soluble in 3.6 parts of water at 25° C. (77° F.), and in 0.4 part of boiling water; very sparingly soluble in alcohol. When heated to 353° C. (667.4° F.) the salt melts. At a higher temperature it is decomposed, giving off oxygen at first, and then some of its nitrogen, leaving a residue of potassium nitrate, nitrite, and oxide. When thrown upon red-hot coals, the salt deflagrates. The aqueous solution is neutral to litmus paper. With sodium bitartrate T.S. the aqueous solution (1 in 20) yields a white, crystalline precipitate. If 5 Cc. of an aqueous solution (1 in 20) be agitated with an equal volume of sulphuric acid, and the liquid be cooled and a crystal of ferrous sulphate be placed in the liquid, a dark brown color should appear around the crystal. If a drop of diphenylamine T.S. be mixed with 5 Cc. of an aqueous solution, and sulphuric acid be slowly added so as to form a separate layer, a deep blue color will appear at the line of contact. An aqueous solution of Potassium Nitrate (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If to 10 Cc. of the aqueous solution of the salt (1 in 20) 1 Cc. of chloroform be added, and if chlorine water be introduced, drop by drop, with agitation, the chloroform should not acquire a violet tint (absence of *iodide*). No yellow color should appear when 0.1 Gm. of the dry salt is sprinkled upon 1 Cc. of pure concentrated sul-

phuric acid (absence of *chlorate* and *perchlorate*)." U. S. "In white crystalline masses or fragments of striated six-sided rhombic prisms, colorless, having a cool saline taste. It is soluble in 4 parts of cold and half its weight of boiling water." Br. It is devoid of water of crystallization, but is apt to contain a portion of liquid mechanically lodged within the substance of the crystals. This is particularly the case with the *large crystals*, and, according to Berzelius, is a source of impurity, as the liquid in question is a portion of the mother water in which they were formed. It is on this account that Berzelius recommends that the solution of the purified salt should be stirred during crystallization, so as to cause it to shoot into *small crystals*. The fused mass, when cast in moulds, or formed into little circular cakes, constitutes that form of nitre found in commerce under the name of *crystal mineral* or *sal prunelle*.¹ If the heat is increased, the salt is decomposed, evolves pure oxygen, and is reduced to the state of nitrite, which, in powder, emits orange-colored fumes of hyponitric acid, and nitrous oxide on the addition of sulphuric acid. Upon a further continuance of the heat, the nitrous acid itself is decomposed, and a large additional quantity of oxygen is evolved, contaminated, however, with more or less nitrogen. On account of the large proportion of oxygen which it affords, nitre increases the combustion of many substances in a remarkable degree. When thrown on burning coals, it deflagrates with bright scintillations. In the reaction of nitre with charcoal, carbonic acid is produced, and never carbonic oxide, and the nitric acid is variously decomposed into nitrous oxide, nitrogen dioxide, or nitrogen, according to the proportion of the charcoal and to the heat employed. (A. Vogel, Jr.)

Potassium nitrate may be very readily recognized by its effect in increasing the combustion of live coals when thrown upon them, and by evolving white or reddish vapors on the addition of sulphuric acid. If the residue in this case weighs less than the amount calculated for potassium sulphate, part of it is probably sodium sulphate, and the nitre tested may be assumed to have contained sodium nitrate. The most usual impurity is sodium chloride, which is seldom entirely absent, and which injures it for the manufacture of gunpowder. The refined or purified saltpetre of commerce is sufficiently pure for medicinal use. Potassium nitrate is composed of one atom of potassium in combination with one nitric acid group, which latter is monobasic.

¹ *Sal prunelle*, as directed to be made in the French Codex of 1837, is a mixture of potassium nitrate and sulphate. It is prepared by fusing nitre in a Hessian crucible, adding 1-128th part of sulphur, and pouring out the product on a smooth marble slab, where it is allowed to congeal. The sulphur immediately takes fire, and, by combining with oxygen from a part of the nitric acid of the nitre, becomes sulphuric acid, which then unites with a small portion of potassium to form potassium sulphate.

Uses.—Potassium nitrate, when in sufficient concentration, acts upon a raw surface or a mucous membrane as a violent irritant, and taken internally in concentrated form produces violent burning pain, vomiting, purging, and other evidences of gastro-enteritis, which may end in collapse and death. Inflammation and ulceration of the mucous membrane are commonly found at the autopsies. In its general action potassium nitrate shares the sedative influence of the potassium salts in general, and was at one time much used as a diuretic and diaphoretic, but is at present very rarely employed, except as a local remedy. It is, however, sometimes prescribed with tartar emetic and calomel, forming the so-called *nitrous powder*, which promotes most of the secretions, particularly those of the liver and skin, and is sometimes advantageous in lessening and modifying febrile excitement. The formula usually preferred is eight or ten grains (0.5 to 0.65 Gm.) of nitre, the eighth of a grain (0.008 Gm.) of tartar emetic, and from one-fourth to one-half of a grain (0.016 to 0.032 Gm.) of calomel, exhibited every two or three hours.

At one time potassium nitrate was used in very large doses in acute *rheumatism*, but the practice has passed out of vogue. It is essential always to give the remedy very freely diluted, if at all, and thus avoid its irritant influence upon the gastro-intestinal tract. An ounce taken in a little water has produced death, while recovery has been known from a dilute solution of several ounces. According to Lauter Brunton potassium nitrate has the same effect on the vascular system as the nitrite except that it is slower in its action. He recommends its use in the early stages of *arterio-capillary fibrosis* and other conditions of high arterial tension.

As a local remedy the nitrate is similar in its action to potassium chlorate, but it is probably less efficient, and certainly has been largely replaced by the chlorate in the treatment of *stomatitis*, *angina*, and local inflammations. In *asthma*, nitrous fumigation is often useful, performed by inhaling the fumes from burning torch paper, prepared by dipping blotting paper in a saturated solution of nitre and afterwards drying it. Such paper was official in the U. S. P. 1890. (See *Charta Potassii Nitratris*, p. 319.) Vohl has examined the vapor resulting from the burning paper thus impregnated, and found it to consist of carbon dioxide and oxide, cyanogen, ammonia, nitrogen, aqueous vapor, and potassium carbonate and nitrite, and he ascribes the beneficial results of its inhalation to the ammonia and potassium nitrite. (*J. P. C.*, 4e sér., iii. 155, 1866.)

In pharmacy, potassium nitrate was formerly employed to form crocus of antimony, to procure nitric acid, and sometimes in the preparation of spirit of nitrous ether. In the laboratory it is used to make black and white flux, as an oxidizing agent, and to yield oxygen at a

red heat. It was formerly employed in the production of aqua fortis (common nitric acid) and in the manufacture of sulphuric acid, and is yet employed in the fabrication of gunpowder. The Br. Pharmacopœia 1885 used it in the purification of bismuth.

Dose, five to ten grains (0.32 to 0.65 Gm.).

POTASSII PERMANGANAS. U. S., Br.

POTASSIUM PERMANGANATE

(pō-tās'sī-I pār-măn'ga-nās)

$\text{KMnO}_4 = 156.98$

"It should contain not less than 99 percent. of pure Potassium Permanganate [MnO_4OK], and should be kept in glass-stoppered bottles, protected from light. Potassium Permanganate, when in concentrated solution or in the dry condition, should not be brought in contact with organic or other readily oxidizable substances." U. S. "Potassium Permanganate, K_2MnO_4 , may be obtained by the interaction of potassium chlorate, potassium hydroxide, and manganese dioxide." Br.

Potasse Permanganas; Kall Hypermanganicum Crystallissatum; Hypermanganas Potassicus, s. Kallcus; Permanganate of Potash; Permanganate de Potasse, Fr. Cod.; Kallum permanganicum, P. G.; Kallumpermanganat, Chameleon, Uebermangansaures Kall, G.; Permanganato di potassio, It.; Permanganato potassico, Sp.

The British Pharmacopœia 1885 furnished a detailed process for this salt, as follows:

"Take of Caustic Potash *five ounces* [avoirdupois]; Black Oxide of Manganese, in fine powder, *four ounces* [av.]; Chlorate of Potassium *three ounces and a half* [av.]; Distilled Water *two pints and a half* [Imperial measure]; Carbonic Acid *a sufficiency*. Reduce the Chlorate of Potassium to fine powder, and mix it with the Oxide of Manganese; put the mixture into a porcelain basin, and add to it the Caustic Potash, previously dissolved in four [fluid]ounces of the Water. Evaporate to dryness on a sand-bath, stirring diligently to prevent spurting. Pulverize the residual mass, place the powder in a covered crucible, exposing it to a dull red heat for an hour, or until it has assumed a semi-fused condition. Let it cool, pulverize it, and boil with a pint and a half [Imp. meas.] of the Water. Let the insoluble matter subside, decant the fluid, boil again with half a pint [Imp. meas.] of the Water, again decant, saturate the united liquors with Carbonic Acid, and evaporate until a pellicle forms. Set aside to cool and crystallize. Drain the crystalline mass, boil it in six [fluid]ounces of the Water, and strain through a funnel, the throat of which is lightly obstructed by a little asbestos. Let the fluid cool and crystallize, drain the crystals, and dry them by placing them under a bell-jar over a vessel containing sulphuric acid."

By this process potassium chlorate yields oxygen to manganese dioxide, converting it into manganic acid, which unites with the potassium hydroxide to form the manganate, potassium chloride being formed at the same time; the reaction being

When this solution is boiled, the potassium manganate reacts with the water and yields potassium permanganate, according to the reaction

the hydrated peroxide separating out. Hence, when exhausted by water, the solution requires the saturation of the free alkali with carbon dioxide, as stated in the process above. At best, the product is small and uncertain in amount. A cheaper commercial preparation, consisting of a mixture more or less pure of sodium manganate and permanganate, is manufactured on a large scale for disinfecting purposes. It is obtained by mixing the sodium hydroxide obtained from 1500 kilogrammes of soda ash with 350 kilogrammes of finely divided manganese dioxide in a flat vessel, and heating this mixture for forty-eight hours to dull redness. The product is then lixiviated with water, and the solution either boiled down to the requisite degree of strength or evaporated to dryness. Potassium permanganate has also been made by the electrolysis of the manganate, the products being permanganate, potassium hydroxide, and hydrogen. A still more interesting result of electrolysis is the production of potassium permanganate by the electrolysis of potassium hydroxide, in which the negative electrode is of porous copper oxide and the positive electrode a piece of manganese or ferro-manganese held immersed by a loop of platinum wire. A process for the complete conversion of manganate into permanganate has been patented in Germany. The crude manganate obtained in the usual way by melting manganese dioxide and alkali under access of air, is exhausted with water and a current of *oxygenized* air is passed into and through the alkaline solution. The conversion of the manganate into permanganate is complete and rapid, whereas when ordinary oxygen is thus introduced the formation is slow and incomplete. (*Ph. Ztg.*, 1901, 517.)

Properties.—It is officially described as in “slender, monoclinic prisms, of a dark purple color, almost opaque by transmitted light, and of a blue, metallic lustre by reflected light, odorless, and having a taste at first sweet, but afterwards disagreeable and astringent. Permanent in the air. Soluble in about 15 parts of water at 25° C. (77° F.), and in 3 parts of boiling water; in contact with alcohol it is decomposed. When heated, the salt decrepitates, and at 240° C. (464° F.) it decomposes, yielding oxygen, potassium manganate, and manganese dioxide. The aqueous solution of

the salt is of a deep violet-red color when concentrated, and of a rose color when much diluted, and the rose color is discharged by hydrogen sulphide, ferrous sulphate, oxalic acid, alcohol, hydrogen dioxide, and many other readily oxidizable substances, especially if the solution be first rendered acid by sulphuric acid. An aqueous solution is neutral to litmus paper. If 0.5 Gm. of Potassium Permanganate be boiled with 20 Cc. of water and 4 Cc. of alcohol until it is completely decomposed, and the liquid then filtered, the clear, colorless filtrate may be used for the following tests: If to 5 Cc. of the filtrate, acidulated with nitric acid, barium chloride T.S. be added, not more than a very slight turbidity should be produced (limit of *sulphate*). In another portion of 5 Cc., acidulated with nitric acid, silver nitrate T.S. should produce no precipitate or cloudiness (absence of *chloride*). If to another portion of 5 Cc. of the filtrate 1 drop of diphenylamine T.S. be added, and then 1 Cc. of sulphuric acid introduced, so as to form a layer beneath, no blue color should appear at the line of contact (absence of *nitrate*). If 0.1 Gm. of Potassium Permanganate be dissolved in about 100 Cc. of hot distilled water to which 1 Cc. of sulphuric acid has previously been added, the solution should require for complete decolorization not less than 31.5 Cc. of tenth-normal oxalic acid V.S.” *U. S.* “Dark purple slender prismatic iridescent crystals, with a sweet astringent taste, soluble in 20 parts of cold *water*, without action on *litmus*. The crystals heated to redness decrepitate, evolve oxygen, and leave a black residue from which *water* extracts potassium hydroxide, the resulting solution affording the reactions characteristic of potassium. It should yield no characteristic reaction with the tests for lead, arsenium, iron, aluminium, calcium, magnesium, sodium, ammonium, carbonates, chlorides, or sulphates. Each gramme dissolved in *water*, and acidulated with 5 cubic centimetres of *diluted sulphuric acid*, should require for complete decolorization 31.2 cubic centimetres of an aqueous solution containing 62.58 grammes of pure crystallized *oxalic acid* per litre.” *Br.*

If the solution be evaporated to dryness, the salt has the form of an intensely black powder. If suddenly heated, the crystals detonate, evolving oxygen, and leaving a black residue, which yields potassium hydroxide to water, recognized by its alkaline reaction, and by giving, when acidulated with hydrochloric acid, a yellow precipitate with platinic chloride.

Moderately heated, the crystals are partially volatilized, giving out violet vapors of a disagreeable metallic odor. (*A. J. P.*, Sept. 1862, p. 409.) The salt, in consequence of the facility with which it parts with oxygen, is one of the most powerful oxidizing agents known. It causes the combustion of certain inflammable bodies, imparts oxygen to almost

all organic substances, and in chemistry is employed to bring various compounds to a higher degree of oxidation. The readiness with which it yields oxygen in the nascent state is sufficient to account for its oxidizing power. It may be kept indefinitely if pure, and carefully secured from contact with organic substances, or other decomposing agents; but in fact, in consequence of the almost universal presence of organic matter in the air, it is generally partially decomposed, and, when dissolved, leaves a slight residue of hydrated manganese dioxide. In reference to the metals, mercury is quickly oxidized at the expense of the salt, a mixture of mercurous oxide and manganese oxide being deposited as a brown powder, and potassium hydroxide remaining in solution. Zinc remains unchanged indefinitely in a solution of the permanganate, silver is little affected, and copper not at all, even at 100° C. (212 F.). (Giles, *J. P. C.*, Mai, 1868, p. 397.)

H. B. Condry introduced (*J. Soc. Chem. Ind.*, 1885, p. 567) a permanganate disinfectant, which contains also aluminum sulphate, which is said to increase the oxidizing effect of the permanganic acid. He asserts that in this disinfectant solution all the available oxygen of the permanganic acid is utilized, whereas only 60 per cent. of this amount is utilized with the simple alkaline permanganate.

Uses.—Potassium permanganate was first brought to the notice of the profession in 1857, by Condry, as a powerful disinfectant, and has proved to be very efficient not only in lessening fetid odors from organic sources, but also in destroying the sources of the odor. It acts by oxidizing, but, as it can yield up only the oxygen within it, its powers are limited. Further, it is a comparatively expensive substance, so that it is very rarely employed when any considerable mass of material is to be affected. It also has the further disadvantage of staining the skin, clothes, etc.; but the stain may be removed with oxalic acid. It is frequently used in the treatment of *fetid and gangrenous ulcers, hospital gangrene, abscesses, carbuncles, and wounds* of all kinds, of fetid discharges from the mucous membrane, as in *ozæna, otorrhæa, gonorrhæa, and leucorrhæa*, and of *diphtheritic affections*; and it has proved serviceable even in *cancerous ulcers*. As a local stimulant it has also been used in *chronic and indolent ulcers*. In all these cases it is applied to the diseased surface in solution of various strengths, according to the effect desired. In concentrated solution it is capable of acting as a caustic and therefore requires caution. With the view to its caustic action, it may be sprinkled on the diseased surface by means of a pepper-box, or applied in saturated solution. As a disinfectant or stimulant lotion it may be of various strengths, from one to twenty grains to the fluidounce of water. In preparing any solution of permanganate for use, it is of the utmost importance to avoid organic matters.

Internally, the medicine has been used in *diphtheria, scarlatina*, and various *zymoses*, and in *dyscrasia*, but is probably of no service. It is plain that any moderate amounts of the permanganate must be decomposed by the organic matters of the mouth, œsophagus, and stomach before absorption. Nevertheless, the value of the permanganate in *atonic amenorrhæa*, first asserted by Sydney Ringer, has been corroborated by Fordyce Barker and other clinicians. It should be given in doses of from one to two grains (0.065 to 0.13 Gm.), after meals, unless it produce too much gastric uneasiness. Pills made with an excipient of cacao butter or rosin cerate, or compressed tablets of the pure salt, may be employed.

Potassium permanganate acts as an oxidizant much more rapidly upon some organic substances than upon others, by virtue of which fact it is a valuable antidote, notably in the treatment of morphine-poisoning and of snake-poisoning.¹ In the latter condition a concentrated solution of it should be injected freely and immediately into the part which has been bitten. (For cases, see *Med. Rec.*, 1894.) In morphine poisoning it acts only upon the alkaloid in the stomach, but should be given from time to time during the continuance of the symptoms in order to destroy any morphine which may have been eliminated from the blood into the stomach.

Dose, from one to two grains (0.065 to 0.13 Gm.).

¹ **Treatment of Snake-bites.**—Potassium permanganate as an antidote to snake poisons was first used by Fayer in 1869, and shown by Blythe in 1877 to be a complete chemical antidote to cobra venom when mixed *in vitro*, his results being confirmed by Lauter Brunton and Fayer in 1878. The two last-named experimenters, together with Rogers, of the Indian medical service, have reported on a method of preventing death from snake-bites, capable of common and easy practical application, and described a simple instrument which was designed by Fayer to meet this requirement, since it can be constantly at hand when wanted and easy of application by unskilled persons. The instrument consists simply of a small lancet about ¾ inch long with a hollow wooden handle, in which crystals of permanganate are contained. The way in which it is proposed to apply the permanganate is that any one bitten by a snake should at once tear a strip from a turban, shirt, or any other article of clothing, and tie it as quickly as possible above the bite. A cut should then be made with the lancet over the site of the bite so as to convert the puncture made by the snake's tooth into a small wound. Into this the crystals of permanganate, moistened with saliva if necessary, are to be rubbed. By means of this instrument, Dr. Rogers has been able to test the effect of permanganate applied in the manner described on rabbits and cats. Five out of six animals experimented upon survived after the injection of cobra poison, and a similar number survived after the use of Dabola poison. These experiments are satisfactory, inasmuch as they show that the utility of permanganate is not confined to one class of venom, but that it acts equally well with the venom of all kinds of snakes. The results obtained five minutes after the injection of the poison were as good as half a minute after injection, so that although very rapid absorption occurs during the first few seconds, it seems probable that absorption soon becomes slow from local effusion, and that sufficient time would thus be afforded for the application of the proposed antidote. (*C. D.*, June 18, 1904, 988.)

POTASSII SULPHAS. U. S., Br.

POTASSIUM SULPHATE

(pō-tās'sī-i sūl'phās)

 $K_2SO_4 = 173.07$

"It should contain not less than 99 percent. of pure Potassium Sulphate $[SO_2(OK)_2]$." *U. S.* "Potassium Sulphate, K_2SO_4 , may be obtained by purifying the crude salt, or by the interaction of sulphuric acid and potassium chloride or certain other potassium salts." *Br.*

Potassæ Sulphas; Sulphas Potassicus, s. Kallcus, Tartarum Vitriolatum, Arcanum Duplicatum, Sal Duobus, Sal Polychrestum Glaseri; Sulphate of Potash, Vitriolated Tartar; Sulfate de Potasse, *Fr. Cod.*; Potasse vitriolée, *Fr.*; Kalium Sulfuricum, *P. G.*; Kaliumsulfat, Schwefelsaures Kali, *G.*; Solfato di Potassio, *It.*; Sulfato potassico, *Sp.*

Several chemical processes give rise to potassium sulphate as a secondary product. Thus, it is produced in the distillation of nitric acid from a mixture of potassium nitrate and sulphuric acid; in the decomposition of magnesium sulphate by potassium carbonate, in one of the processes for preparing magnesium carbonate; in the manufacture of sulphuric acid; in the manufacture of potassium dichromate; and in the decomposition of potassium tartrate by calcium sulphate. When nitric acid is obtained by calcining a mixture of nitre and ferrous sulphate, the residue consists of ferric oxide and potassium sulphate, the latter of which, being alone soluble, is separated by means of water, and crystallized from its solution. The impure potassium sulphate with sulphur, forming the residue of the combustion of sulphur and nitre in making sulphuric acid, is employed in the manufacture of alum. The *kainite* of the Stassfurt salt beds is a native double potassium and magnesium sulphate, combined with magnesium chloride, and the *schænite*, a double potassium and magnesium sulphate, with 6 molecules of water. To obtain potassium sulphate, the former mineral is exposed to the air; it deliquesces, and as soon as the soluble magnesium chloride has been run off, the remaining salt is partially decomposed by boiling water, so that on cooling the difficultly soluble sulphate separates out. About 12,000 tons of the potassium sulphate so obtained are annually put upon the market for use in fertilizers. The production of *kainite* at Stassfurt, in Germany, amounted in 1903 to 1,557,243 tons, valued at \$5,445,750; and in 1904 to 1,905,893 tons, valued at \$6,641,250.

According to the directions of the former *Br. Pharmacopœia*, the acid sulphate which remains after the distillation of nitric acid is brought to the neutral state by saturation, in boiling solution, with slaked lime. The solution is then filtered, to separate the calcium sulphate, and potassium carbonate is added at the boiling temperature, to remove lime and calcium sulphate. It is again filtered, then either neutral-

ized or rendered slightly acid with diluted sulphuric acid, and finally, having been evaporated to a pellicle, is set aside for twenty-four hours to crystallize. The manufacturer of tartaric acid who avails himself of calcium sulphate to decompose potassium tartrate forms potassium sulphate as a collateral product. For the manner in which the latter salt may be economically crystallized for use, see *A. J. P.*, xxiii. 343.

Properties.—As officially described, it is in "hard, colorless, transparent, six-sided, rhombic prisms terminated by pyramids, or a white powder, odorless, and having a somewhat bitter, saline taste. Permanent in the air. Soluble in about 9 parts of water at 25° C. (77° F.), and in 4 parts of boiling water; insoluble in alcohol. When heated, the crystals decrepitate. At a bright red heat they fuse, and at a white heat the salt suffers partial decomposition. The aqueous solution is neutral to litmus paper. The saturated aqueous solution of the salt yields a white, crystalline precipitate with excess of sodium bitartrate T.S. An aqueous solution of the salt (1 in 20) yields with barium chloride T.S. a heavy white precipitate, insoluble in hydrochloric acid. The aqueous solution of Potassium Sulphate (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). Five Cc. of the aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzeit's Test for *arsenic* (see PART III, Test No. 17)." *U. S.* "In colorless hard rhombic prisms terminated by six-sided pyramids; decrepitates strongly when heated; soluble in 10 parts of cold and 4 parts of boiling water; insoluble in alcohol (90 per cent.). The salt affords the reactions characteristic of potassium and of sulphates. Each gramme dissolved in water and acidulated with hydrochloric acid, gives, with solution of barium chloride, a white precipitate, which, when washed and dried, should weigh 1.339 grammes. It should not yield any characteristic reaction with the tests for lead, copper, arsenium, iron, aluminium, zinc, calcium, magnesium, sodium, ammonium, or nitrates, and only the slightest reactions with the tests for chlorides. The aqueous solution has no action on *litmus* (absence of acid potassium sulphate)." *Br.* It consists of two atoms of potassium combined with the dyad group, SO_4 , characteristic of sulphuric acid.

The *plate-sulphate of potassa*, so well described by Penny of Glasgow, is, when pure, the double potassium and sodium sulphate, having the formula $3K_2SO_4 + Na_2SO_4$. It is so called from the circumstance of being crystallized in hard thick cakes, or slabs, consisting of successive crops of crystals. It is a technical product from kelp, and may be formed by allowing successive quantities of concentrated kelp-lye to run into coolers, there to crystallize in successive layers, the mother liquor being drawn off by a siphon after the deposit of each layer. (*Phil. Mag.*, Dec. 1855.) For the mode of preparing and using *Sal Polychrestum*, *Po-*

tassii Sulphas cum Sulphure, or *Sulphate of Potassa with Sulphur*, see U. S. D., 15th ed., p. 1187.

Uses.—Potassium sulphate is a mild purgative, operating usually without heat, pain, or other symptom of irritation. In small doses, of from twenty grains to half a drachm (1.3 to 2.0 Gm.), it operates as an aperient; in larger doses, of four or five drachms (15.5 to 19.4 Gm.), it acts slowly as a purge. On the continent of Europe it is frequently given as an aperient after delivery, and for the purpose of drying up the milk. Potassium sulphate is a powerful irritant in excessive doses, and capable of producing fatal poisoning; an ounce and a half (46.5 Gm.) of it are said to have caused death. It is, like the nitrate and the chlorate, more dangerous when not given in sufficiently dilute solution. (See *Am. J. M. S.*, N. S., vii. 88.)

Dose, twenty grains to four drachms (1.3 to 15.5 Gm.).

POTASSII TARTRAS. *Br.*

POTASSIUM TARTRATE

(pō-tās'sī-tī tīr'trās)

$K_2C_4H_4O_6$. $H_2O = 467.16$

"Normal Potassium Tartrate $(CHOH)_2(COOK)_2 \cdot H_2O$, is obtained by neutralizing Acid Potassium Tartrate with potassium carbonate." *Br.*

Potasse Tartras; *Tartras Potassicus*, s. *Kalicus*; *Tartarus Tartarizatus*, *Tartarus Solubilis*; *Tartrate of Potash*; *Soluble Tartar*; *Tartrate de Potasse neutre*, *Fr. Cod.*; *Tartre soluble Sel végétal*, *Fr.*; *Kallum Tartaricum*, *P. G.*; *Kallumtartrat*, *G.*; *Tartrato neutro di potassio*, *It.*; *Tartrato potassico neutro*, *Sp.*

This salt was dropped at the 1890 revision of the U. S. Pharmacopœia; it is retained in the 1898 revision of the British authority.

In the U. S. 1870 process¹ the excess of acid in the bitartrate is saturated by the potassium of the carbonate, the carbon dioxide is liberated with effervescence, and the neutral potassium tartrate is formed. On account of the greater solubility of the carbonate than of the bitartrate, the former is first dissolved, and the latter added to the solution to full saturation. As the bitartrate is gradually added, the mutual action of the salts should be promoted by constant stirring, and the addition continued so long as effervescence takes place, which is a better mode of proceeding than to add any specified

quantity of the acid tartrate, since, from its variable quality, it is impossible to adjust precisely the proportions applicable to all cases. It is necessary that the solution should be exactly neutral, or a little alkaline, and hence, if inadvertently too much bitartrate has been used, the proper state may be restored by adding a little of the alkaline carbonate. When the saturation has been completed, the solution is filtered, in order to separate calcium tartrate, which appears in white flocks, and which is always present in cream of tartar as an impurity. The evaporated liquor should then be placed in warm earthenware vessels, to insure a slow refrigeration, and after remaining at rest for several days the crystals begin to form. In order that the crystallization should proceed favorably, it is necessary, according to Baumé, that the solution should be somewhat alkaline. Iron vessels should not be used in the process, as that metal is apt to discolor the salt.

Potassium tartrate is sometimes made in the process for preparing tartaric acid. When thus obtained, the excess of acid of the bitartrate is neutralized by means of calcium carbonate. This generates an insoluble calcium tartrate, and leaves the neutral tartrate in solution, from which it may be obtained by evaporation and crystallization. (See *Acidum Tartaricum*.)

Properties.—Potassium tartrate was officially described in the U. S. P. 1880 as in "small, transparent or white, monoclinic crystals, or a white powder, somewhat deliquescent, odorless, having a saline, slightly bitter taste, and a neutral reaction. Soluble in 0.7 part of water at 15° C. (59° F.), and in 0.5 part of boiling water; almost insoluble in alcohol. When heated, the salt melts, then chars, and evolves inflammable vapors having the odor of burnt sugar. On moderate ignition, it leaves a blackened residue of an alkaline reaction, strongly effervescing with acids. A concentrated, aqueous solution of the salt yields a white, crystalline precipitate on the addition of acetic acid. With test-solution of nitrate of silver it yields a white precipitate which becomes black on boiling." For medicinal use it should be crystallized; but as it ordinarily occurs in commerce it is a white granular powder, obtained by evaporating the solution to dryness while it is constantly stirred. In this state it is said to require four times its weight of water for solution. It is not known to be purposely adulterated, but, if obtained by evaporation to dryness, it is liable to contain an excess of potassium carbonate or bitartrate, when it will have either an alkaline or an acid reaction. It is decomposed by all the strong acids, and by many acidulous salts, which cause the precipitation of minute crystals of potassium bitartrate, by abstracting one atom of alkali from the salt. Barium chloride or lead acetate occasions a white precipitate of barium or lead tartrate, distinguishable from the sulphates of those bases by being wholly soluble in dilute nitric acid. "A 10 per cent. aqueous solution should yield no precipitate with

¹ "Take of Carbonate of Potassium *sixteen Troy-ounces*; Bitartrate of Potassium [*cream of tartar*], in fine powder, *thirty-six Troy-ounces*, or a *sufficient quantity*; Boiling Water *eight pints*. Dissolve the Carbonate of Potassium in the Water; then gradually add Bitartrate of Potassium to the solution until it is completely saturated, and boil. Filter the liquid, evaporate it until a pellicle forms, and set it aside to crystallize. Lastly, pour off the mother-water, and, having dried the crystals on bibulous paper, keep them in a well-stoppered bottle." *U. S.* 1870.

test-solution of ammonium oxalate (absence of calcium). On adding nitric acid to a one per cent. solution of the salt, until the precipitate first formed is redissolved, the resulting solution should yield no precipitate with test-solution of barium chloride (sulphate), and, at most, only a cloudiness with test-solution of silver nitrate (limit of chloride). If 2.938 Gm. of Potassium Tartrate are ignited till gases cease to be evolved, the alkaline residue should require, for complete neutralization, not less than 25 C.c. of the volumetric solution of oxalic acid (corresponding to 100 per cent. of pure Potassium Tartrate)." *U. S.* 1880. "In small colorless four- or six-sided prisms. It is soluble in its own weight of water. It affords the reactions characteristic of potassium and of tartrates. Each gramme of the dry salt, heated to redness till gases cease to be evolved, should leave an alkaline residue, which, when treated with water, filtered, and well washed, yields a clear solution requiring for exact neutralization 8.4 cubic centimetres of the volumetric solution of sulphuric acid. It should yield no characteristic reaction with the tests for lead, copper, or iron, and only the slightest reactions with the tests for calcium, magnesium, sodium, chlorides, or sulphates. The aqueous solution has no action on *litmus* (absence of acid potassium tartrate)." *Br.* Potassium tartrate is composed of two atoms of potassium combined with the dyad group $\text{C}_4\text{H}_4\text{O}_6$ characteristic of tartaric acid.

Uses.—Potassium tartrate is a mild, cooling purgative, operating, like most of the neutral salts, without much pain, and producing watery stools. It is applicable to *febrile diseases*, and is occasionally combined with senna, the gripping effects of which it has a tendency to obviate.

Dose, from a drachm to an ounce (3.9 to 31 Gm.).

POTASSIUM.

POTASSIUM

(pō-tās'si-ŭm)

K = 38.86

Potassium, *Fr.*; Kallum, *Kalimetall*, *G.*; Potassio, *It.*; Potasico, *Sp.*

Potassium is a metal forming the radical of potassium hydroxide, and of a number of compounds used in medicine. It was discovered in 1807 by H. Davy, who obtained it by decomposing fused potassium hydroxide by a voltaic current. It was afterwards procured in larger quantity by Gay-Lussac and Thénard, by bringing the fused alkali in contact with white-hot iron, which attracted the oxygen and set free the metal. The process of Brunner, as modified by Wöhler, consists in decomposing potassium carbonate, mixed with charcoal. The mixture of carbonate and charcoal is obtained by heating cream of tartar to redness in a covered crucible. For an account of some improvements in Brunner's process by Mareska and Donny, see *A. J.*

P., xxv. 70. Castner has also prepared it by the process invented by him for the manufacture of metallic sodium. (See *Sodium*.)

Potassium is solid, softer and more ductile than wax, easily cut with a knife, and of a silver-white color. A newly-cut surface is brilliant, but the metal quickly tarnishes by combining with the oxygen of the air, and assumes the appearance of lead. It possesses a remarkably strong affinity for oxygen, and is capable of taking that element from almost every other substance. On account of this property it must be kept in liquids, such as naphtha, which are devoid of oxygen. On the same account, when exposed with a freshly cut surface to the air, it becomes luminous through a slow combustion, like phosphorus, in the dark. (*Chem. News*, Feb. 28, 1868, p. 108.) Its sp. gr. is 0.865, melting point 62.5°C . (144.5°F .), atomic weight 38.86, and symbol K. When thrown upon water it floats, takes fire, and burns with a rose-colored flame, combining with oxygen, and generating potassium hydroxide which dissolves in the water. It forms numerous combinations, uniting with most of the non-metallic elements, and with several of the metals. It combines in three proportions with oxygen, forming a suboxide (K_2O) and a monoxide (K_2O) of a gray color, and a tetroxide (K_2O_4) of a yellowish-brown color. It also unites with chlorine, and forms official compounds with iodine, bromine, cyanogen, and ferrocyanogen, under the names of potassium iodide, bromide, cyanide, and ferrocyanide. Its monoxide is a strong salifiable base existing in nature always in combination, and forming with acids a numerous and important class of salts.

PRUNUM. U. S., Br.

PRUNE

(prá'nŭm)

"The partly dried ripe fruit of *Prunus domestica* Linné (Fam. *Rosaceæ*)."
"The dried ripe fruits of *Prunus domestica*, Linn., var. *Juliana*, DC." *Br.*

Prunes; Pruneau noir, *Fr.* *Cod.*; Pflaume, *Zwet-sche*, *G.*

Prunus domestica, Willd., *Sp. Plant.* ii. 995; Woodv., *Med. Bot.* p. 520, t. 17.—The cultivated prune or plum tree is so well known as to render a minute description unnecessary. We give merely the specific character. "*Peduncles* sub-solitary; *leaves* lanceolate-ovate, convolute; *branches* not spiny." The varieties of the tree produced by cultivation are very numerous. Nearly one hundred are to be found in the British gardens. Though at present growing wild in various parts of Europe, it is thought to have been brought originally from Asia Minor and Syria. It is the dried fruits only that are official. They are officially described as "ob-long, ellipsoidal, more or less compressed, 3 to 4 Cm. long; externally brownish-black, shriv-

elled; the sarcocarp sweet and acidulous; putamen hard, smooth or irregularly ridged; the seed, shaped like that of the almond but smaller, and of a bitter-almond taste." *U. S.* The prunes brought to our market come chiefly from the south of France, the best from Bordeaux. They are derived from the variety of the tree named *Juliana* by Linnæus. The fresh fruit, called *Prune de Saint-Julien* by the French, is of an oval shape, nearly an inch in length, and of a deep violet color. It is prepared by drying in the sun, after having been exposed to the heat of an oven. The finest prunes, used on the tables in France, are prepared from the larger kinds of plums, such as the *Saint Catharine*, and *Reine Claude* or *greengage*. An inferior sort is brought from Germany.

Prunes have a feeble odor, and a sweet mucilaginous taste, which is generally also somewhat acid. They contain uncrystallizable sugar, malic acid, and mucilaginous matter. The following is given as the average of nine analyses of dried prunes. Water 29.30 per cent., nitrogenous material 2.35 per cent., fat 0.53 per cent., free acid 2.72 per cent., sugar 44.35 per cent., other nitrogen-free material 17.89 per cent., woody fibre (not including the stone) 1.48 per cent., ash 1.38 per cent. (König, *Nahrungsmittel*, ii. 397, 1880.) In Hungary a kind of brandy (*Zwetschenbranntwein*), containing about 40 per cent. of alcohol, is obtained from them, which in some districts is largely consumed. Bonneberg, a German chemist, has extracted from prunes crystallizable sugar equal to that of the cane.

Uses.—Prunes are laxative and nutritious, and, stewed with water, form an excellent diet in *costiveness*. Imparting their laxative property to boiling water, they serve as a pleasant and useful addition to purgative decoctions. Their pulp is used in the preparation of laxative confections. Too largely taken, they are apt to occasion flatulence, griping, and indigestion.

PRUNUS VIRGINIANA. U. S. (Br.)

WILD CHERRY

(prū'nūs vir-jîn-l-ā'nə)

"The bark of *Prunus serotina* Ehrhart (*Prunus virginiana* Miller) (Fam. *Rosaceæ*), which should be collected in autumn and carefully dried and preserved." *U. S.* "The bark of *Prunus serotina*, Ehrh., collected in autumn." *Br.*

Pruni Virginianæ Cortex, *Br.*, Virginian Prune Bark; Rum, Whisky, or Cabinet Cherry, Wild Black Cherry; Ecorce de Cerisier de Virginie, *Fr.*; Wildkirschensrinde, Amerikanischer Zierstrauch, *G.*

The genus *Prunus* now includes the plums, almonds, peaches, apricots, and cherries, and comprises about one hundred and twenty species. They are generally distributed in the temperate

regions of the northern hemisphere. In the United States there are about forty indigenous species.

Prunus serotina, Ehrhart; Watson's *Bibliographical Index*.—*Cerasus* (not *Prunus*) *serotina*, Loiseleur. *Nouv. Duhamel* (1812), v. 3.; De Candolle, *Prodrom.* ii. 540.—*Cerasus virginiana*, Michaux, *Fl. Bor.-Am.*, i. 285.—The name *P. virginiana* was applied by Miller (*Dict.*, ed. 8, No. 3), and not Linnæus, to *P. serotina*, Ehr. *P. virginiana*, L., commonly called *wild cherry* or *choke cherry*, is distinguished from *P. serotina*, Ehr., known more properly as *wild black cherry*, by the following characteristics: *P. virginiana*, L., has deciduous calyx lobes; oblong-obovate pointed endocarp (or stone); leaves broadly oval to oblong-obovate, and usually abruptly acuminate; inner bark with a rather disagreeable odor. *P. serotina*, Ehr., has persistent calyx lobes; the endocarp (or stone) oblong-obovate, usually gradually acuminate; leaves oblong or lanceolate-oblong, usually gradually acuminate; the inner bark and leaves possess an aromatic odor. The British name for the bark is misleading; Virginian Peach Bark or Virginian Almond Bark would have been no more of a misnomer. The official species is, according to Michaux, one of the largest productions of the American forest. Trees were observed by that botanist on the banks of the Ohio, from eighty to one hundred feet high, with trunks from twelve to fifteen feet in circumference, and undivided to the height of twenty-five or thirty feet. But as usually met with in the Atlantic States the tree is much smaller. In the open fields it is less elevated than in forests, but sends out more numerous branches, which expand into an elegant oval summit. The trunk is regularly shaped, and covered with a rough blackish bark, which detaches itself semicircularly in thick narrow plates. The leaves are alternate, oval-oblong, or lanceolate-oblong, acuminate, unequally serrate, smooth on both sides, of a beautiful brilliant green; the petioles are furnished with one or more reddish conspicuous glands. The flowers are small, white, and occur in long erect or spreading racemes. They appear in May, and are followed by globular drupes, about the size of a pea, and when ripe of a shining blackish-purple color. For a paper on the structure of species of *Prunus*, by E. S. Bastin, see *Proc. A. Ph. A.*, 1895, 211.

This tree is distributed from Nova Scotia south to Florida, and westward to Dakota, Nebraska, Kansas, Indian Territory, and Eastern Texas. It extends along the mountain ranges of Western Texas, Mexico, and Pacific regions of Central America, Colombia, and Peru. In the United States it was once common throughout the Appalachian region. In the neighborhood of Philadelphia it affects open situations, growing solitarily in the fields and along fences, and seldom aggregated in woods or groves. It is highly valued by the cabinet-makers for its wood, which is compact, fine-grained, susceptible of polish, and of a light red tint which deepens

with age. The leaves have been found by Procter to yield volatile oil and hydrocyanic acid on distillation, and in such proportion that a water distilled from them might with propriety be substituted for the cherry-laurel water. (*Proc. A. Ph. A.*, 1858, 325.) The fruit has a sweetish, astringent, bitter taste, and is much used in some parts of the country to impart flavor to spirituous liquors. The bark is obtained indiscriminately from all parts of the tree, though that of the roots is thought to be most active. The revisers of the Pharmacopœia believe with J. S. Perot that the bark is stronger when collected in autumn than in the spring; from a portion gathered in April Perot obtained 0.0478 per cent. of hydrocyanic acid, and from another in October 0.1436 per cent., or about three times as much. (*A. J. P.*, xxiv, 111.) The bark should be preferred recently dried, as it deteriorates by keeping. A. B. Stevens (*Proc. A. Ph. A.*, 1895, 226; 1896, 215), after testing many specimens, reached the conclusion that bark procured from different parts of the same tree varied in the yield of hydrocyanic acid, the value being in this order; 1, root; 2, twigs; 3, trunk; the bark from young trees yielding more glucoside than that from old trees. Jos. L. Lemberger (*A. J. P.*, 1872, 303) has found that the bark yields the darkest infusion in April, October, and November, and the lightest in January and August, and believes that he has demonstrated that the coloration is due to tannic acid. According, therefore, to this investigation, tannic acid is most abundant in the bark in October and November. On the other hand, Grace E. Cooley (*A. J. P.*, August, 1897) concludes that there is more tannic acid in the bark during the active growth of the spring than in the autumn. She further states that in the spring and autumn the bark contains its maximum percentage of starch; so that if the bark, whether powdered or whole, contains much starch in its parenchymatous cells, it has been collected after the time of leaf-fall in the autumn or before the unfolding of the leaves in the spring. Occasionally barks find their way into commerce as *Prunus Virginiana* which yield no odor of hydrocyanic acid when moistened and are probably obtained from other than the official wild cherry. (See Bastin, *A. J. P.*, 1895, and Finnemore, *P. J.*, 72.)

Properties.—Wild cherry bark is officially described as follows. "Usually in transversely curved pieces from 3 to 7 Cm. long, 0.5 to 4 Mm. thick; outer surface pale green to greenish-brown, smooth, with numerous lenticels; inner surface light brown, somewhat reticulately striate or fissured; fracture short, granular; having a bitter-almond-like odor when macerated in water; taste astringent, aromatic, and agreeably bitter." *U. S.* It is brittle and pulverizable, presenting a reddish gray fracture, and affording a fawn-colored powder. In the fresh state, or when treated with water, it emits an odor resembling that of peach leaves. Its taste is agreeably bitter and aro-

matic, with the peculiar flavor of the bitter almond. It imparts its sensible properties to water, either cold or hot, producing a clear reddish infusion closely resembling Madeira wine in appearance. Its peculiar flavor and its medicinal virtues are injured by boiling, in consequence partly of the volatilization of the principles upon which they depend, partly upon a chemical change effected by the heat. On microscopical examination it is seen to be chiefly composed of brown parenchymatous tissue containing numerous crystals, sometimes aggregated into tufts, and enclosing numerous groups of very thick-walled sclerenchymatous cells of irregular outline. The medullary rays are usually distinct. From an analysis by Stephen Procter, it appears to contain starch, resin, tannin, gallic acid, fatty matter, lignin, red coloring matter, salts of calcium, potassium, and iron. He obtained also a volatile oil, associated with hydrocyanic acid, by distilling the same portion of water successively from several different portions of the bark. William Procter proved that, as in the case of bitter almonds, the volatile oil and hydrocyanic acid do not exist ready formed in the bark, but are the result of the reaction of water with amygdalin, which he ascertained to be one of its constituents. In order, however, that this change may take place, the agency of another principle, probably analogous to if not identical with *emulsin* or the *synaptase* of Robiquet, is also essential, and, as this principle becomes inoperative at the boiling temperature, we can understand how decoction may interfere with the virtue of the bark. (*A. J. P.*, x, 197.) Phlorizin has not been found, so that the tonic property which is undoubtedly possessed by the bark must reside either in the portion of amygdalin which may remain undecomposed, in the pure volatile oil resulting from its reaction with water, or in some yet undiscovered principle. (*Ibid.*, xxiv, 111.) That the last of these inferences is the correct one would seem to be proved by an experiment by Procter, who found the bitterness of an extract of the bark to remain after it had been wholly deprived of amygdalin. The sedative properties of the bark depend upon the hydrocyanic acid which it yields. Stevens and Judy (*A. J. P.*, 1895, 482 and 534) found that the thick bark contains more amygdalin and consequently yields more HCN than the thin bark. The thick bark contains amygdalin, etc., 4.12 per cent., and HCN from 0.32 to 0.35 per cent.; the thin bark, amygdalin, etc., 3.16 per cent., and HCN from 0.24 to 0.27 per cent.

R. Rother (*A. J. P.*, 1887, p. 286), in searching for the fluorescent principle of wild cherry bark, obtained a reddish crystalline substance, soluble in water, chloroform, ether, and alcohol, the solution of which fluoresced strongly on addition of ammonia. Rother says that it does not agree in crystalline form with mandelic acid, but may be a derivative of it. F. B. Power and Henry Weimer, on the other hand,

state that the bark does not contain crystallizable amygdalin, that the ferment principle is not emulsin, and that it cannot be isolated by an analogous process. The bitter principle, which appears to be the fluoescence substance, has the character of a glucoside, and crystallizes in colorless needles. (*West. Drug.*, 1887, p. 331.)

Uses.—Uniting with a tonic power the property of calming irritation and diminishing nervous excitability, this bark is theoretically adapted to the treatment of diseases in which *debility of the stomach or of the system* is united with *general or local irritation*; and when very largely taken it diminishes the action of the heart. Thus, Eberle found copious draughts of the cold infusion, taken several times a day, and continued for nearly two weeks, to reduce his pulse from seventy-five to fifty strokes in the minute. But in the doses usually prescribed, the remedy is too feeble to exert much influence. Nevertheless, it has been much employed in this country, in the *hectic fever of scrofula and consumption*. The dose of the infusion, which is properly directed in the Pharmacopœia to be prepared with cold water, is two or three fluidounces (60 or 90 Cc.); of the fluidextract, a fluidrachm (3.75 Cc.); and of the syrup,¹ half a fluidounce (15 Cc.).

Dose, from thirty to sixty grains (2.0 to 3.9 Gm.).

PULVERES.

POWDERS

(pŭl've-rēs)

Poudres, Fr.; Pulvern, G.; Polveri, It.; Polvos, Sp.

The form of powder is convenient for the exhibition of substances which are not given in very large doses, are not very disagreeable to the taste, have no corrosive property, and do not deliquesce rapidly on exposure. As the effect of pulverization is to expose a more extended surface to the action of the air, care should be taken to keep substances which are liable to be injured by such exposure in closely-stoppered bottles. In many instances it is also important to exclude the light, which exercises a deleterious influence over numerous medicines when minutely divided. This may be done by coating the bottles with black varnish, or by using amber-colored glass bottles which exclude the injurious rays of light.

In relation to substances most liable to injury from these causes, the best plan is to powder them in small quantities as wanted for use.¹

Powders may be divided into the *simple*, consisting of a single substance, and the *compound*, of two or more mixed together. The latter only are embraced under the present head. In the preparation of the compound powders, the ingredients, if of different degrees of cohesion or solidity, should be pulverized separately and then mixed. Deliquescent substances, and those containing fixed oil in large proportion, should not enter into the composition of powders intended to be kept,—the former because they render the preparation damp and liable to spoil, the latter because they are apt to become rancid and impart an unpleasant odor and taste. When deliquescent substances are extemporaneously prescribed, the apothecary should enclose them before delivery in waxed paper or other impervious covering; and the same remark is applicable to volatile powders, as ammonium carbonate and camphor. The lighter powders may in general be administered in water or other thin liquid; the heavier, such as those of metallic substances, require a more consistent vehicle, as syrup, molasses, honey, or one of the confections. Resinous powders, if given in water, require the intervention of mucilage or sugar. For many powders the *cachet de pain* affords the best method of administration.²

¹ With regard to keeping powders in well-stoppered bottles, it is asserted by Hérouard, a French pharmacist, that this plan, instead of preserving *some* powders, tends to their more speedy and certain change. Whatever pains may be taken in drying drugs previously to powdering them, most of them during the process attract moisture, so as to put themselves in this respect in equilibrium with the surrounding air; and, if enclosed in this state in air-tight vessels, they are exposed to injurious influence from their own absorbed water, which, vaporized in hot weather, is in the colder seasons condensed on the inner surface of the vessel and determines a movement of fermentation, and even cryptogamic growths appear in some instances. The best method of preservation, the author thinks, is to enclose the powders in strong paper bags of a blue or gray color, so as to exclude the light, while the air has exit or entrance through the porous walls. Whatever may be our theoretical opinions on the point, Hérouard asserts the fact, as the result of observation, that powders keep best in this way, and his statement coincides with our own experience. The powders may be more likely to cake or harden into aggregate masses; but this disadvantage is easily counteracted by a new pulverization when required. (*J. P. O.*, Août, 1862, p. 98.) From these statements the inference may be drawn that, where powders are kept in air-tight bottles, they should be thoroughly dried, after pulverization, before being enclosed, and many, such as ergot, iodo-barb, etc., should be kept in paper boxes or cartons.

² **Cachets.**—These very useful articles are wafers made of unleavened bread in such a manner that they offer a concavity, so that when two are placed face to face there is a space in which a powder may be contained. They are of different sizes and capacities, the largest readily holding as much as ten grains of quinine. In filling them, one wafer is placed upon a board, and the requisite amount of medicine is put in it; then a second wafer, whose interior margin has been wetted, is laid upon the first and pressed down upon it. When taken, they should be dipped in water, placed immediately upon a teaspoon containing a little water, and swallowed with a gulp of fluid. For most powders of disagreeable taste, cachets afford the best method of administration.

¹ *Tinctura Pruni Virginianæ* B. P. O.—Take of wild-cherry bark (from *Prunus serotina*, Ehrhart, collected in autumn), in No. 20 powder, 4 ounces; distilled water, 7½ fluidounces. Macerate for twenty-four hours, in a closed vessel, and add: Rectified spirit, 12½ fluidounces. Macerate for seven days; then express, filter, and add sufficient proof spirit to make 1 pint. (*Proc. A. Ph. A.*, 1888, p. 285.)

In the act of powdering, the whole substance in the mortar should not be beaten until completely pulverized, as the portion already powdered interferes with the action of the pestle upon the remainder, while the finer matter is apt to be dissipated, so that there is a loss of time and of material. The proper plan is to sift off the fine powder after a short continuance of the process, then to return the coarser parts to the mortar, and to repeat several times this alternate pulverization and sifting, until the process is completed. Care should be taken to mix thoroughly the several portions of fine powder thus obtained.

PULVIS ACETANILIDI COMPOSITUS. U. S.

COMPOUND ACETANILIDE POWDER

(pŭl'vis äc-ë-tän-î-lî'di côm-pôs'î-tŭs)

Poudre d'Acétanilide composée, *Fr.*; Zusammengesetztes Antifebrinpulver, *G.*

* "Acetanilide, *seventy grammes* [or 2 ounces av., 205 grains]; Caffeine, *ten grammes* [or 154 grains]; Sodium Bicarbonate, *twenty grammes* [or 309 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Reduce the ingredients separately to a fine powder and mix them thoroughly." *U. S.*

This compound powder was introduced into the U. S. P. (8th Rev.) in order to afford a convenient formula for administering acetanilide.

Uses.—This formula represents the essential composition of most of the proprietary headache powders, and is useful in the treatment of *migraine* and *neuralgia*.

Dose, five to ten grains (0.32 to 0.65 Gm.).

PULVIS AMYGDALÆ COMPOSITUS. Br.

COMPOUND POWDER OF ALMONDS

(pŭl'vis ä-mÿg'dä-læ côm-pôs'î-tŭs)

Confectio Amygdalæ; Conserva Amygdalarum; Confection of Almond; Conserve d'Amandes, *Fr.*; Mandelconserven, *G.*

"Sweet Almonds, 8 ounces (Imperial) or 200 grammes; Refined Sugar, in powder, 4 ounces (Imp.) or 100 grammes; Gum Acacia, in powder, 1 ounce (Imp.) or 25 grammes. Steep the Almonds in water until their skins can easily be removed; when thus blanched, dry them as far as possible with a cloth, and then thoroughly by exposure in a warm place for twenty-four hours; rub them lightly in a mortar to a smooth consistence; mix the Gum Acacia and the Sugar; add this mixture, gradually, to the bruised Almonds; rub the whole to a coarse powder." *Br.*

This is the old *Almond Confection* under a new name. It is intended to afford a speedy method of preparing the almond mixture, which, when made immediately from the almonds,

requires much time, and which cannot be kept ready made. But from its liability to be injured by keeping, it was omitted from the U. S. Pharm., which directs the emulsion of almond to be made immediately from the ingredients.

Off. Prep.—Mistura Amygdalæ, *Br.*

PULVIS ANTIMONIALIS. Br.

ANTIMONIAL POWDER [James's Powder]

(pŭl'vis än-tî-mô-nî-ä'lîs)

Pulvis Antimonii Compositus, Pulvis Jacobi; Poudre antimoniale de James, *Fr.*; Jamessches Antimonpulver, *G.*

"Antimonious Oxide, 1 ounce (Imperial) or 25 grammes; Calcium Phosphate, 2 ounces (Imp.) or 50 grammes. Mix." *Br.*

This preparation was introduced into the U. S. Pharmacopœia 1890 as a substitute for the different forms of antimonial powder formerly official with the British Colleges, because of its revived employment at that time, but was not admitted to the U. S. P. (8th Rev.). The U. S. P. 1890 and the British preparations are identical. In order that the subject may be properly understood, it will be necessary to introduce a notice of the powder as formerly directed to be prepared by the London and Dublin Colleges; the process of the Edinburgh College was so similar to the London that it does not require special consideration.

Antimonial Powder of the London College. "Take of Tersulphate of Antimony, powdered, a pound; Horn shavings two pounds. Mix, and throw them into a red-hot crucible, and stir constantly until vapor ceases to rise. Rub the residue to powder, and put it into a crucible. Then apply heat, and raise it gradually to redness, and keep it so for two hours. Rub the remaining powder until it is as fine as possible." *Lond.*

This preparation consists mainly of calcium bone phosphate, or calcined bone, mixed with antimonious acid, and is intended to furnish a substitute for the celebrated nostrum of James, an English physician who died in 1776, and after whom the original preparation was called *James's powder*. Pearson of London, found the genuine powder, on analysis, to consist of calcium phosphate and oxidized antimony, and, guided by his results, devised the formula adopted by the London College. By burning the materials directed by the College, the sulphur is expelled in the form of sulphurous acid, and the antimony oxidized, while the horn, which is of the nature of bone, has its animal matter converted into charcoal. By the subsequent calcination the charcoal is dissipated, leaving only the calcium phosphate of the horn mixed with the antimony oxide.

The antimonial powder made by this formula is a tasteless, inodorous, gritty powder, of a dull white color. As often prepared, it is insoluble in water, but usually a small portion, consisting of antimonite and acid calcium

phosphate, dissolves in boiling distilled water. Its composition varies exceedingly, a circumstance which forms a strong objection to it as a medicine. When entirely insoluble in boiling water, it probably contains nothing but antimonious acid and calcium phosphate, for when its soluble constituents are absent the trioxide is absent also.

The only essential difference between the official and the Dublin powder is that the ingredients of the former are taken already prepared and mixed in fixed proportion, while those of the latter result simultaneously from one operation. The official powder is, of course, much more easily prepared, and less liable to uncertainty from any error in the process.¹

Uses.—This preparation is stated to be alterative, diaphoretic, purgative, or emetic, according to the dose in which it is given. Until within a few years it was often prescribed in febrile diseases, with a view to its diaphoretic effect. According to A. T. Thomson, it is advantageously given in *acute rheumatism*, conjoined with camphor, calomel, and opium, and with calomel and guaiac in several *cutaneous affections*. The estimation in which this preparation is held varies greatly; but it is generally admitted that, as formerly prepared, it was very uncertain in the percentage of antimony trioxide, and consequently in its activity; it was this uncertainty that led to its omission from the U. S. Pharm. of 1830.

The antimonial powder at present official is exempt from the objection of irregularity of composition. Nevertheless, as it depends for its greater or less energy on the presence or absence in the alimentary canal of an acid which may form a salt with the antimonial oxide, it cannot always be relied on for a definite effect, being sometimes mild, and sometimes more active than might be desirable.

Dose, as a diaphoretic, from three to eight grains (0.2 to 0.5 Gm.) every third or fourth hour, given in the form of pill. In larger doses it is purgative and emetic. Jonathan Osborne has found the trioxide, given separately in three grain (0.2 Gm.) doses, evening and night, to cause in some cases nausea and vomiting, in others mild purgation. (*P. J.*, 1855, p. 331.)

PULVIS AROMATICUS. U. S. (Br.)

AROMATIC POWDER

(pŭl'vīs ā-rŏ-măt'ī-cŭs)

Pulvis Cinnamomi Compositus, Br.; Compound Powder of Cinnamon; Poudre des Epices, *P.* des Aromates, Poudre aromatique, *Fr.*; Aromatisches Pulver, *Gewürzpulver, G.*

*"Saigon Cinnamon, in No. 60 powder, *thirty-five grammes* [or 1 ounce av., 103

grains]; Ginger, in No. 60 powder, *thirty-five grammes* [or 1 ounce av., 103 grains]; Cardamom, deprived of pericarps and crushed, *fifteen grammes* [or 231 grains]; Myristica, in No. 20 powder, *fifteen grammes* [or 231 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Triturate the Cardamom and Myristica with a portion of the Saigon Cinnamon, until they are reduced to a fine powder; then add the remainder of the Saigon Cinnamon and the Ginger, and rub them together until they are thoroughly mixed." *U. S.*

"Cinnamon Bark, in powder, 1 ounce (Imperial) or 25 grammes; Cardamom Seeds, in powder, 1 ounce (Imp.) or 25 grammes; Ginger, in powder, 1 ounce (Imp.) or 25 grammes. Mix." *Br.*

The Aromatic Powder of the U. S. P. (8th Rev.) does not differ essentially from that formerly official. The British and American powders now closely resemble each other. The present British formula differs from that of 1864 in the substitution of ginger for nutmeg, cloves, and saffron, and especially in the absence of sugar, which in the latter constituted two-thirds of the whole, having probably been added in order that, by the addition of a little water to the powder, a confection might be quickly made, thus enabling the dispensing of a fresh preparation. It is obvious that this end may be as effectually attained by the addition of a little syrup to the present powder.¹ The cardamom seeds should always be deprived of their pericarps before being weighed, and the powder, when prepared, should be kept in well-stoppered bottles. The aromatic powder is stimulant and carminative, and the U. S. preparation may be given in the dose of from ten to thirty grains (0.65 to 2.0 Gm.), in cases of *enfeebled digestion with flatulence*; but it is chiefly used as a corrigent and adjuvant of other medicines. A mixture of aromatic powders in the form of a cataplasm is much used as a mild rubefacient, especially in nausea and vomiting, being applied over the epigastrium. Such mixtures are commonly called *spice plasters*. The following is a good formula. Take of ginger, cloves, cinnamon, and black pepper, each, in powder, an ounce; tincture of ginger half a fluidounce; honey a sufficient quantity. Mix the powders, and then add the tincture and honey, so as to form a stiff cataplasm; or the mixed powder may be distributed in a thin flannel bag, quilted in position, and the whole wet with bathing whisky when applied and covered with oiled silk.

Dose, ten to thirty grains (0.65 to 2.0 Gm.).

¹Michael Donovan believes that none of the official formulas fairly represent James's powder, and gives an elaborate history of this celebrated proprietary medicine, and a method for its preparation, in *P. J.*, 1869.

¹**Aromatic Sugar.**—Wm. L. Turner proposed a mode of obtaining the effects of the aromatic powder in certain cases where the use of the powder itself would be inconvenient. He prepared an aromatic sugar by submitting eight ounces of the freshly prepared powder to percolation with stronger alcohol to exhaustion, pouring the percolate over eight ounces of sugar, and evaporating at a low heat. The sugar thus prepared may be added to mixtures, solutions, etc., requiring aromatic addition. (*A. J. P.*, 1869, p. 118.)

Off. Prep.—Fluidextractum Aromaticum, *U. S.*; Pilulæ Aloes et Ferri, *U. S.* (*Br.*); Pilulæ Aloes et Myrrhæ, *U. S.*; Pilula Cambogiæ Composita, *Br.*

PULVIS CATECHU COMPOSITUS. *Br.*

COMPOUND POWDER OF CATECHU

(pŭl'vis căt'ē-ghŭ côm-pŏs'ī-tŭs)

Poudre de Cashuttle composée, *Fr.*; Zusammengesetztes Katechupulver, *G.*

"Catechu, in powder, 4 ounces (Imperial) or 100 grammes; Kino, in powder, 2 ounces (Imp.) or 50 grammes; Krameria Root, in powder, 2 ounces (Imp.) or 50 grammes; Cinnamon Bark, in powder, 1 ounce (Imp.) or 25 grammes; Nutmeg, in powder, 1 ounce (Imp.) or 25 grammes. Mix." *Br.*

The dose of this agreeable preparation is from fifteen to thirty grains (1 to 2 Gm.).

PULVIS CRETÆ AROMATICUS. *Br.*

AROMATIC POWDER OF CHALK

(pŭl'vis crē'tæ ār-q-măt'ī-cŭs)

Confectio Aromatica, *Lond.*; Poudre de Cræle aromatique, *Fr.*; Gewürztes Kreidepulver, *G.*

"Cinnamon Bark, in powder, 4 ounces (Imperial) or 80 grammes; Nutmeg, in powder, 3 ounces (Imp.) or 60 grammes; Cloves, in powder, 1½ ounces (Imp.) or 30 grammes; Cardamom Seeds, in powder, 1 ounce (Imp.) or 20 grammes; Refined Sugar, in powder, 25 ounces (Imp.) or 500 grammes; Prepared Chalk, 11 ounces (Imp.) or 220 grammes. Mix." *Br.*

This is the former "Aromatic Powder" of the *Br. Pharmacopœia*, with the addition of chalk and elision of saffron. It is a warm stimulant and astringent, as well as antacid, and is well calculated for *diarrhœa* connected with acidity and without inflammation. In such a combination, however, the due proportion and even the choice of the ingredients vary so much with the symptoms that they might well be left to extemporaneous prescription.

Dose, from thirty to sixty grains (2.0 to 3.9 Gm.), in mucilage or sweetened water, frequently repeated.

Off. Prep.—Pulvis Cretæ Aromaticus cum Opio, *Br.*

PULVIS CRETÆ AROMATICUS CUM OPIO. *Br.*

AROMATIC POWDER OF CHALK WITH OPIUM

(pŭl'vis crē'tæ ār-q-măt'ī-cŭs cŭm ō'pī-ō)

Poudre de Cræle Opiacée, *Fr.*; Kreidepulver mit Opium, *G.*

"Aromatic Powder of Chalk, 9½ ounces (Imperial) or 39 grammes; Opium, in powder, ½ ounce (Imp.) or 1 gramme. Mix. This Powder contains 2½ per cent. of Opium." *Br.*

The addition of the opium greatly increases the efficacy of the compound powder of chalk in *diarrhœa*, and its equal diffusion through the powder presents this advantage, that it may be conveniently given in minute doses applicable to infantile cases. Forty grains of the powder contain a grain of opium. In the *diarrhœa* of adults ten to twenty grains (0.65 to 1.3 Gm.) may be given for a *dose*, and repeated several times a day, or after each evacuation.

PULVIS CRETÆ COMPOSITUS. *U. S.*

COMPOUND CHALK POWDER

(pŭl'vis crē'tæ côm-pŏs'ī-tŭs)

Poudre de Cræle composée, *Fr.*; Kreidepulver mit Gummi, *G.*

* "Prepared Chalk, thirty grammes [or 1 ounce av., 25 grains]; Acacia, in fine powder, twenty grammes [or 309 grains]; Sugar, in fine powder, fifty grammes [or 1 ounce av., 334 grains], to make one hundred grammes [or 3 ounces av., 231 grains]. Mix intimately." *U. S.*

This official powder was introduced into the *U. S. P.* 1890, for the purpose of having on hand, in a convenient form, the dry powders necessary to make chalk mixture. (See *Mistura Cretæ*.)

This powder will be found, however, a very convenient basis for administering chalk in powder, and it will be easy to direct the addition of morphine, kino, pepsin, bismuth subnitrate, or any other suitable agent.

Dose, one-half to two drachms (2.0 to 7.7 Gm.).

Off. Prep.—*Mistura Cretæ, U. S.*

PULVIS EFFERVESCENS COMPOSITUS. *U. S.* (*Br.*)

COMPOUND EFFERVESCING POWDER [Selditz Powder]

(pŭl'vis ēf-fēr-vēs'cens côm-pŏs'ī-tŭs)

Pulvis Sodæ Tartaratæ Effervescens, *Br.*; Effervescent Tartarated Soda Powder; Pulveres Effervescentes Aperientes, *U. S.* 1870; Selditz Powders; Poudre Gazogène laxative, *Fr. Cod.*; Poudre gazifère purgative, Poudre de Selditz, *Fr.*; Pulvis ærophorus laxans, *P. G.*; Pulvis ærophorus Selditzensis, Abführendes Brausepulver, Selditzpulver, *G.*; Polvo gasífero laxante, *Sp.*

* "Sodium Bicarbonate, dried and in fine powder, thirty-one grammes [or 1 ounce av., 41 grains]; Potassium and Sodium Tartrate, dried and in fine powder, ninety-three grammes [or 3 ounces av., 123 grains]; Tartaric Acid, dried and in fine powder, twenty-seven grammes [or 417 grains]. Mix the Sodium Bicarbonate intimately with the Potassium and Sodium Tartrate, divide the mixture into twelve equal parts, and wrap each part in a separate blue paper. Then divide the Tartaric Acid into twelve equal parts, and wrap each part in a separate white paper. Keep the powders in well-closed containers, in a dry place." *U. S.*

"Sodium Potassium Tartrate, in dry powder, 120 grains or 7.77 grammes; Sodium Bicar-

bonate, in dry powder, 40 grains or 2.59 grammes. Mix. Wrap in blue paper. Tartaric Acid, in dry powder, 38 grains or 2.46 grammes. Wrap in white paper. *Dose, for a draught.*—The alkaline powder (in blue paper) dissolved in nearly half a pint of cold or warm water, and the acid powder (in white paper) then added." *Br.*

The British Pharmacopœia, under the name of *Pulvis Sodæ Tartarata Effervescens*, introduced in the 1885 revision those well known powders, which are universally called Seidlitz powders. Though named from the saline springs of Seidlitz, in Bohemia, Seidlitz powders do not correspond in composition with those famous waters. Of each pair of powders, one, much the smaller of the two, contains about thirty-five grains (2.25 Gm.) of tartaric acid, the other about forty grains (2.59 Gm.) of sodium bicarbonate mixed with about two drachms (7.7 Gm.) of Rochelle salt. The acid powder is usually put into a white paper, the alkaline into a blue paper, which latter should not be colored by aniline; a number of them are enclosed in a paper or tin box. They should not be kept in a damp place, as the tartaric acid is liable to be dissolved by the moisture and absorbed into the substance of the paper, thus altering the due proportion of the ingredients. We have known the whole of the contents of the white paper thus to disappear in the course of two or three years. The Rochelle salt is the ingredient upon which the aperient property mainly depends. In their administration, each powder is dissolved separately, the smaller in a fluidounce or more of water, the larger in twice or three times the quantity, and the two solutions are mixed gradually. A reaction takes place between the tartaric acid and the sodium bicarbonate, by which sodium tartrate is produced, adding somewhat to the laxative property of the draught, and carbon dioxide escapes, causing a brisk effervescence. The acid is in slight excess, and thus causes an agreeable acidity in the solution. These powders are refrigerant and aperient, and generally very acceptable to the stomach in consequence of the carbon dioxide eliminated. They are especially adapted to *febrile cases* with a somewhat irritable stomach. One pair of them will generally operate slightly, but, if required, two may be given at once, or the dose may be repeated every three or four hours until the desired effect is produced. The flavor may sometimes be advantageously improved by adding syrup of ginger, orange peel, or lemon to one of the solutions before admixture, and most persons prefer to dissolve the salts in very cold water, the saline taste being thereby greatly diminished. A lowering of the temperature always takes place, due to the solution of the salts.¹

Dose, one set of two powders.

PULVIS ELATERINI COMPOSITUS.

Br.

COMPOUND POWDER OF ELATERIN

(pŭl'vis ē-lăt-ē-rī'nī cōm-pōs'ī-tūs)

"Elaterin, 5 grains or 1 gramme; Milk Sugar, 195 grains or 39 grammes. Triturate in a mortar until a fine powder is produced." *Br.*

This official powder of the British Pharmacopœia is identical with the trituration of elaterin of the United States Pharmacopœia, except that it is of but one-fourth its strength.

The *dose* is given in the British Pharmacopœia as from one to four grains (0.065 to 0.26 Gm.).

PULVIS GLYCYRRHIZÆ COMPOSITUS.

U. S., Br.

COMPOUND POWDER OF GLYCYRRHIZA [Compound Licorice Powder]

(pŭl'vis glŷ-ē-rhī-zæ cōm-pōs'ī-tūs)

Poudre de Réglisse composée, Poudre pectorale, *Fr.*; Pulvis Liquiritiæ Compositus, *P. G.*; Brustpulver, Pulvis Pectoralis Kureliæ, *G.*

* "Senna, in No. 80 powder, one hundred and eighty grammes [or 6 ounces av., 153 grains]; Glycyrrhiza, in No. 80 powder, two hundred and thirty-six grammes [or 8 ounces av., 142 grains]; Washed Sulphur, eighty grammes [or 2 ounces av., 360 grains]; Oil of Fennel, four grammes [or 62 grains]; Sugar, in fine powder, five hundred grammes [or 17 ounces av., 279 grains], to make one thousand grammes [or 35 ounces av., 120 grains]. Mix the Oil of Fennel thoroughly with about one-half of the Sugar, then add the remainder of the Sugar and the other ingredients, and mix thoroughly. Finally, pass the powder through a No. 80 sieve, pulverize the residue if any should be left on the sieve, add to the sifted powder, and mix thoroughly. Keep it in well-closed vessels." *U. S.*

"Senna, in fine powder, 2 ounces (Imperial) or 50 grammes; Liquorice Root, in fine powder, 2 ounces (Imp.) or 50 grammes; Fennel Fruit, in fine powder, 1 ounce (Imp.) or 25 grammes;

cus, P. G.; Poudre gazeuse, *P. atrophore, P. de Seltz, Fr.*; Brausepulver, *G.*—"Take of Bicarbonate of Sodium, in fine powder, three hundred and sixty grains; Tartaric Acid, in fine powder, three hundred grains. Divide each of the powders into twelve equal parts, and keep the parts, severally, of the Bicarbonate and of the Acid in separate papers of different colors." *U. S.* 1870. *Soda Powders* consist, severally, of twenty-five grains (1.565 Gm.) of the acid in one paper, and thirty (1.95 Gm.) of the bicarbonate in the other. They are administered in solution. An acid and an alkaline powder may be dissolved in separate portions of water and then mixed; or they may be thrown together, or successively, into the same portion of water. The whole draught should be half a pint or somewhat less. It may be rendered more agreeable by adding two or three fluidrachms (7.5 to 11.25 Cc.) of syrup of ginger or orange peel to the water, before dissolving the powders. The rationale is simple. The tartaric acid seizes the alkali of the bicarbonate, forming a sodium tartrate, while the carbon dioxide escapes with effervescence. The effervescing powders are refrigerant and slightly laxative, and afford an agreeable and refreshing drink, suitable to febrile complaints, and generally very acceptable to the stomach.

¹ *Pulveres Effervescentes. U. S.* 1870. *Effervescing Powders. Soda Powders. Pulvis Atrophorus Angli-*

Sublimed Sulphur, 1 ounce (Imp.) or 25 grammes; Refined Sugar, in powder, 6 ounces (Imp.) or 150 grammes. Mix." Br.

This official preparation, which was introduced into the U. S. P. 1880, was identical with that of the German Pharmacopœia, and in the 1885 revision of the British Pharmacopœia the preparation was made nearly to correspond, being slightly deficient in senna. The U. S. P. 1890 replaced the powdered fennel with oil of fennel, increasing the proportion of powdered licorice correspondingly,—which is an improvement, as powdered fennel is variable in quality; great care should be used, however, to employ only fresh oil of fennel. The object of the oil of fennel is patent, but the advantage to be gained by the use of washed sulphur in the proportion of only 8 per cent. must be purely imaginary. In our opinion, an improvement would be the substitution of two grammes each of powdered cinnamon and cloves for four grammes of the sugar, to correct the griping effect which is frequently produced.

Dose, thirty to sixty grains (2.0 to 3.9 Gm.), used as an agreeable laxative.

PULVIS IPECACUANHÆ ET OPII.

U. S. (Br.)

POWDER OF IPECAC AND OPIUM [Compound Powder of Ipecac, Dover's Powder]

(pŭl'vis ip-ē-cac-ū-ān'hæ ēt ō'pī-i)

Pulvis Ipecacuanhæ Compositus, Br., U. S. 1870; Compound Powder of Ipecacuanha; Poudre d'Ipecacuanha Oplacée, Fr. Cod.; Poudre de Dover, Fr.; Pulvis Ipecacuanhæ Opiatus, P. G.; Doversches Pulver, G.; Polvere di oppio e di ipecacuana, Polvere del Dover, It.; Polvo de ipecacuana opiado, Polvo de Dover, Sp.

* "Ipecac, in No. 60 powder, *ten grammes* [or 154 grains]; Powdered Opium, *ten grammes* [or 154 grains]; Sugar of Milk, in No. 30 powder, *eighty grammes* [or 2 ounces av., 360 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Triturate them together thoroughly and reduce to a very fine powder." U. S.

"Ipecacuanha Root, in powder, $\frac{1}{2}$ ounce (Imperial) or 10 grammes; Opium, in powder, $\frac{1}{2}$ ounce (Imp.) or 10 grammes; Potassium Sulphate, in powder, 4 ounces (Imp.) or 80 grammes. Mix." Br. This powder contains 10 per cent. of powdered Opium.

The substitution of powdered sugar of milk for potassium sulphate in crystals as formerly used cannot be said to have improved this well-known powder, except in making it more agreeable to the taste. The U. S. process should have directed the powder to be sifted, in order to secure a thorough blending of the ingredients; the sifting should on no account be omitted by the operator. The potassium sulphate or the crystalline sugar of milk serves to promote that minute division and consequent thorough intermixture of the opium and ipecacuanha upon which the peculiar virtues of the compound de-

pend, the potassium sulphate being preferable on account of the greater hardness of its particles. They also serve to dilute the active ingredients, and thus allow of their division into minute doses adapted to the complaints of children. This composition, though called Dover's Powder, does not precisely correspond with that originally recommended by Dover, which was prepared as follows: Four ounces of potassium nitrate and the same quantity of potassium sulphate were mixed in a red hot crucible, and afterwards very finely powdered; one ounce of opium, sliced, was then added, and ground to powder with the saline mixture; lastly, an ounce of ipecac and an ounce of licorice root, in powder, were mixed with the other ingredients. This process was adopted in a former French Codex, and has been retained with little change in the present. For a method of valuing Dover's Powder, by A. B. Prescott, see *A. J. P.*, Dec. 1878.

This powder is an admirable anodyne diaphoretic, applicable to all cases, not attended with much fever, cerebral disease, or sick stomach, in which there is an indication for diaphoresis, especially in painful affections, or in those connected with unhealthy discharges. It is admirably adapted to the *phlegmasiæ*, particularly *rheumatism* and *pneumonia*, *dysentery*, *diarrhæa*, etc., when not contra-indicated by existing symptoms. In bowel affections, and whenever the hepatic secretion is deranged, it is frequently combined with small doses of calomel. Ten grains of the powder contain one grain of opium.

Dose, from five to fifteen grains (0.32 to 1.0 Gm.), given diffused in water, or mixed with syrup, or in the form of bolus, and repeated at intervals of four, six, or eight hours, when it is desirable to maintain a continued diaphoresis. Its action may be promoted by warm drinks, such as lemonade or balm tea.

Off. Prep.—Pilula Ipecacuanhæ cum Scilla, Br.

PULVIS JALAPÆ COMPOSITUS.

U. S., Br.

COMPOUND POWDER OF JALAP [Pulvis Purgans]

(pŭl'vis ja-lā'pæ com-pōs'ī-tūs)

Pulvis Purgans, Pulvis Jalapæ Tartratus, Pulvis Catharticus; Poudre de Jalap composée, Fr.; Jalapenpulver mit Weinstein, G.

* "Jalap, in No. 60 powder, *thirty-five grammes* [or 1 ounce av., 103 grains]; Potassium Bitartrate, in fine powder, *sixty-five grammes* [or 2 ounces av., 128 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Rub them together until they are thoroughly mixed." U. S.

"Jalap, in powder, 5 ounces (Imperial) or 100 grammes; Acid Potassium Tartrate, in powder, 9 ounces (Imp.) or 180 grammes; Ginger, in powder, 1 ounce (Imp.) or 20 grammes. Mix." Br.

The rubbing of the bitartrate with the jalap is thought to favor its more minute division, while it increases its hydragogue effect. A combination of these two ingredients, though with a larger proportion of cream of tartar (see *Jalapa*), forms a good cathartic in *dropsy*, and in *scrofulous diseases of the joints and glands*.

Dose, of the powder, from thirty grains to a drachm (2.0 to 3.9 Gm.).

PULVIS KINO COMPOSITUS. Br.

COMPOUND POWDER OF KINO

(pŭl'vis kí'nō cəm-pōs'ī-tŭs)

Pulvis Kino cum Opio, Br. 1864; Powder of Kino and Opium; Poudre de Kino Oplacée, Fr.; Kino pulver mit Opium, G.

"Kino, in powder, $3\frac{1}{2}$ ounces (Imperial) or 75 grammes; Opium, in powder, $\frac{1}{4}$ ounce (Imp.) or 5 grammes; Cinnamon Bark, in powder, 1 ounce (Imp.) or 20 grammes. Mix. This Powder contains 5 per cent. of Opium." *Br.*

This is an anodyne astringent powder, useful in some forms of *diarrhœa*, but of which the composition would be better left to extemporaneous prescription, as the proportion of the ingredients should vary with the circumstances. Twenty grains contain one grain of opium.

Dose, from five to twenty grains (0.32 to 1.3 Gm.).

PULVIS MORPHINÆ COMPOSITUS.

U. S.

COMPOUND POWDER OF MORPHINE

[Tully's Powder]

(pŭl'vis mōr-phī'næ cəm-pōs'ī-tŭs)

Pulvis Camphoræ Compositus Tully; Poudre de Tully, Fr.; Tullysches Pulver, G.

* "Morphine Sulphate, one and one-half grammes [or 23.4 grains]; Camphor, thirty-two grammes [or 1 ounce av., 56 grains]; Glycyrrhiza, in No. 80 powder, thirty-three grammes [or 1 ounce av., 72 grains]; Precipitated Calcium Carbonate, thirty-three and one-half grammes [or 1 ounce av., 79.6 grains]; Alcohol, a sufficient quantity, to make one hundred grammes [or 3 ounces av., 231 grains]. Rub the Morphine Sulphate with the Precipitated Calcium Carbonate, added in portions of about five grammes each, until it is thoroughly mixed, then rub the Camphor with a little Alcohol until it is reduced to a powder, and mix intimately with the Glycyrrhiza and the other powders. Finally, pass the powder through a No. 40 sieve, pulverize the residue if any should be left on the sieve, add to the sifted powder, and mix thoroughly. Transfer it to well-stoppered bottles." *U. S.*

This official compound powder originated with Wm. Tully of New Haven, Conn., who devised it as a substitute for Dover's Powder. It is

very necessary to comply strictly with the directions of Tully in its preparation, *i.e.*, to mix the ingredients thoroughly and then sift the powder, and this last direction is included in the official formula (8th Rev.). The diaphoretic action depends largely upon the intimate admixture of the ingredients. There is the one-sixty-seventh of a grain of morphine sulphate in one grain of the powder.

Dose, ten grains (0.65 Gm.), containing about one-sixth of a grain (0.01 Gm.) of morphine sulphate.

PULVIS OPII COMPOSITUS. Br.

COMPOUND POWDER OF OPIUM

(pŭl'vis ō'pī-i cəm-pōs'ī-tŭs)

Poudre d'Opium composée, Fr.; Zusammengesetztes Opiumpulver, G.

"Opium, in powder, $1\frac{1}{2}$ ounces (Imperial) or 30 grammes; Black Pepper, in powder, 2 ounces (Imp.) or 40 grammes; Ginger, in powder, 5 ounces (Imp.) or 100 grammes; Caraway Fruit, in powder, 6 ounces (Imp.) or 120 grammes; Tragacanth, in powder, $\frac{1}{2}$ ounce (Imp.) or 10 grammes. Mix. This Powder contains 10 per cent. of Opium." *Br.*

This seems to have been introduced in order to have at hand all the dry ingredients of the Confection of Opium. (See *Confectio Opii*.) Ten grains (0.65 Gm.) of the powder contain one grain (0.065 Gm.) of opium.

PULVIS RHEI COMPOSITUS. U. S., Br.

COMPOUND POWDER OF RHUBARB

(pŭl'vis rhē'i cəm-pōs'ī-tŭs)

Magnesia and Rhubarb, Gregory's Powder; Poudre de Rhubarbe composée, Fr.; Pulvis Magnesie cum Rheo, P. G.; Kinderpulver, Pulvis Infantum, s. P. Antacidus, G.

* "Rhubarb, in No. 60 powder, twenty-five grammes [or 386 grains]; Magnesium Oxide, sixty-five grammes [or 2 ounces av., 128 grains]; Ginger, in No. 60 powder, ten grammes [or 154 grains], to make one hundred grammes [or 3 ounces av., 231 grains]. Rub the Rhubarb and Ginger together, and finally the Magnesium Oxide, gradually added, until they are thoroughly mixed." *U. S.*

"Rhubarb Root, in powder, 2 ounces (Imperial) or 50 grammes; Light Magnesia, 6 ounces (Imp.) or 150 grammes; Ginger, in powder, 1 ounce (Imp.) or 25 grammes. Mix. If a less bulky powder be desired, Heavy Magnesia may be employed." *Br.*

This is a good laxative antacid, well adapted to bowel complaints, especially in children.

Dose, for an adult, from one-half to one drachm (2.0 to 3.9 Gm.); for a child two or three years old, from five to ten grains (0.32 to 0.65 Gm.).

PULVIS SCAMMONII COMPOSITUS. Br.**COMPOUND POWDER OF SCAMMONY**

(pŭl'vis scam-mō'nī-i cōm-pōs'ī-tūs)

"Scammony Resin, in powder, 4 ounces (Imperial) or 100 grammes; Jalap, in powder, 3 ounces (Imp.) or 75 grammes; Ginger, in powder, 1 ounce (Imp.) or 25 grammes. Mix." Br.

This does not appear to us a very eligible preparation.

Dose, from ten to twenty grains (0.65 to 1.3 Gm.).

PULVIS TRAGACANTHÆ COMPOSITUS.**Br.****COMPOUND POWDER OF TRAGACANTH**

(pŭl'vis trāg-a-cān'thæ cōm-pōs'ī-tūs)

"Tragacanth, in powder, 1 ounce (Imperial) or 25 grammes; Gum Acacia, in powder, 1 ounce (Imp.) or 25 grammes; Starch, in powder, 1 ounce (Imp.) or 25 grammes; Refined Sugar, in powder, 3 ounces (Imp.) or 75 grammes. Mix." Br.

This is applicable to the general purposes of the demulcents, but is chiefly employed in Great Britain as a vehicle for heavy insoluble powders.

Dose, one-half to one drachm (2.0 to 3.9 Gm.).

PYRETHRUM. U. S. (Br.)**PYRETHRUM (Pellitory)**

(pŷ-rē'thrŭm)

"The root of *Anacyclus Pyrethrum* (Linné) De Candolle (Fam. *Compositæ*)." U. S. "The dried root of *Anacyclus Pyrethrum*, DC." Br.

Pyrethri Radix, Br.; Radix Pyrethri Roman!; Pellitory Root, Spanish Chamomile, Longwort, Pellitory of Spain; Pyréthre officinal, *Fr. Cod.*; P. vral, Salvalre, *Fr.*; Bertramwurzel, Römische Bertramwurzel, *G.*; Pellitre (Raiz de), *Sp.*

Anacyclus Pyrethrum, De Cand., *Prodrum*. vi. 15.—*Anthemis Pyrethrum*, Willd., *Sp. Plant.* iii. 2184; *B. & T.* 151.—The root of this plant is perennial, and sends up numerous stems, usually trailing at the base, erect in the upper portion, eight or ten inches high, and terminated by one large flower. The leaves are doubly pinnate, with narrow nearly linear segments of a pale-green color. The florets of the disk are yellow; the rays white on their upper surface, and reddish or purple beneath and at their edges.

The plant is a native of the Levant, Barbary, and the Mediterranean coast of Europe. The root is the part used under the name of pellitory, or *pellitory of Spain*. According to Hayne, the pellitory of commerce is derived from the *Anacyclus officinarum*, a plant cultivated in Thuringia for medicinal purposes. This statement, however, can apply only to Germany.

Properties.—The dried root of *A. Pyrethrum*¹ is about the size of the little finger, cylindrical, straight or but slightly curved, wrinkled longitudinally, of an ash-brown color externally, whitish within, hard and brittle, and sometimes furnished with a few radicles. It is destitute of odor, though, when fresh, of a disagreeable odor. Its taste is peculiar, slight at first, but afterwards acidulous, saline and acrid, attended with a burning and tingling sensation over the whole mouth and throat, which continues for some time and excites a copious flow of saliva. It is officially described as "somewhat fusiform, nearly simple, 5 to 10 Cm. long, 3 to 20 Mm. in diameter; externally dark brown or grayish-brown, longitudinally wrinkled and somewhat furrowed, crown somewhat annulate and sometimes tufted with coarse fibres or with soft woolly hairs; fracture short; bark dark brown, resinous, 0.5 to 1 Mm. thick, closely adhering to the light yellow, radiate, porous wood; odor distinct; taste pungent, very acrid, producing a prompt sialogogue effect." U. S. The fractured surface shows that the wood is traversed by large medullary rays in which, as well as in the cortex, are numerous dark resin ducts. Its analysis by Koene gives, in 100 parts, 0.59 of a brown, very acrid substance, of a resinous appearance, and insoluble in potassium hydroxide; 1.06 of a dark brown, very acrid, fixed oil, soluble in potassium hydroxide; 0.35 of a yellow acrid oil, also soluble in potassium hydroxide; traces of tannin; 9.40 parts of gum; inulin; 7.60 parts of potassium sulphate and carbonate, potassium chloride, calcium phosphate and carbonate, alumina, silica, etc., and 19.80 of lignin, besides loss. (See *A. J. P.*, viii. 175.) Buchheim (*A. E. P. P.*, 5, 458) claims to have discovered as the active principle an alkaloid, *pyrethrine*, which, treated with alcoholic potassium hydroxide, splits up like piperine, and yields *pyrethric acid*. Schneegans (*Proc. A. Ph. A.*, 1897, 736) has obtained this pyrethrine in long branched needles united in tufts, melting at 46° C. (114.8° F.), with an extremely burning taste. It is soluble in absolute alcohol, acetone, ether, strong acetic acid, chloroform, and carbon disulphide. It is also dissolved by strong sulphuric acid, yielding a yellow solution, which soon changes to red.

Uses.—Pellitory is a powerful irritant, used almost exclusively as a sialogogue in certain forms of *headache*, *rheumatic* and *neuralgic affections* of the face, *toothache*, etc., or as a local stimulant, in *palsy of the tongue or throat*, and in *relaxation of the uvula*. For these purposes it may be chewed, or employed as a gargle in decoction or vinous tincture. The

¹ *False Pellitory Root.*—A root which has been identified by E. M. Holmes as the product of *Corrigiola telephifolia* has been offered in the London market as pellitory. It is readily distinguished from the true root by its being softer and more flexible, by its having a distinctly sweetish taste, and especially by the transverse section of the root, which is of a yellowish-white color, with from three to five pale opaque concentric rings, each alternating with a narrower translucent horny ring.

dose as a masticatory is from thirty grains to a drachm (2.0 to 3.9 Gm.). Its action upon the general system has not been studied to any extent, but 50 minims of a tincture of it very nearly killed a child three and a half years old. The symptoms were those of gastro-enteritis, followed by convulsions. (*London Practitioner*, Aug. 1876.) An alcoholic extract is sometimes employed by dentists as a local anæsthetic application to *carious teeth*.

Dose, twenty grains (1.3 Gm.).

Off. Prep.—Tinctura Pyrethri, *U. S., Br.*

PYROGALLOL. U. S.

PYROGALLOL [Pyrogallie Acid]

(pŷ-rŏ-gă'lŏl)

$C_6H_3O_3 = 125.10$

"A triatomic phenol [$C_6H_3(OH)_3$ 1:2:3], obtained chiefly by carefully heating gallic acid. Pyrogallol should be kept in dark amber-colored bottles." *U. S.*

Acidum Pyrogallicum; Trihydroxybenzene; Pyrogallol, *Fr. Cod.*; Acide Pyrogallique, *Fr.*; Pyrogallolum, *P. G.*; Pyrogallol, Pyrogallussaure, *G.*; Pirogallolo, *It.*

Of the three triatomic phenols indicated by theory, this is the best known, phloroglucin and oxyhydroquinone being the other two. It may be prepared synthetically, but is usually obtained as one of the results of the igneous decomposition of gallic acid, and may be obtained by submitting extract of galls to the same treatment as that used for preparing benzoic acid from benzoin, the reaction being:

The vapors of pyrogallol rise, and condense on the upper surface of the paper diaphragm. The chief difficulty in the process is to properly regulate the heat, as at a high temperature this acid passes rapidly into metagallie acid, and thus the product is diminished. According to Löwig, it is best prepared by heating gallic acid, previously dried at 100° C. (212° F.), in a glass retort, by means of a zinc chloride bath, to 210° C. (410° F.), when the pure acid sublimes. It is stated by De Luynes and Espandieu that in the ordinary method of obtaining pyrogallie acid much of the acid is lost. According to Pelouze, the proportion of pyrogallie acid produced ought to be very nearly 75 per cent., but the processes in use yield only 25 per cent., the pyrogallie acid itself undergoing rapid decomposition at an elevated temperature. De Luynes and Espandieu have succeeded in preventing this loss by decomposing gallic acid in water under pressure, instead of by dry sublimation. Gallic acid is introduced into a bronze boiler with twice or three times its weight of water; the temperature is raised to a point ranging from 200° C. (392° F.) to 210° C. (410° F.), and maintained at that point for half an hour, when the liquid is allowed to cool. The boiler now contains a slightly colored solution of pyrogallie acid. This is heated

with a little pure animal charcoal, filtered, evaporated sufficiently, and set aside to crystallize. The crystalline mass obtained is somewhat colored. To obtain it entirely white, nothing more is necessary than to distil it in a vacuum. The product is quite 75 per cent. The carbon dioxide escapes through the joinings of the apparatus, while the aqueous vapor is retained. (*A. J. P.*, 1866, p. 22.) Another equally satisfactory procedure is that of Thorpe, for details of which see *A. J. P.*, 1881, p. 53, 236.

Properties.—It is officially described as in "light, white laminae or fine needles, odorless and having a bitter taste; acquiring a grayish tint on exposure to air and light. Soluble in 1.6 parts of water, 1 part of alcohol, and in 1.1 parts of ether at 25° C. (77° F.); very soluble in boiling water, and in boiling alcohol. When heated to 132° C. (269.6° F.) Pyrogallol melts and sublimes unchanged. When ignited it is consumed, leaving no residue. The freshly prepared aqueous solution is neutral to litmus paper and colorless, but gradually acquires by exposure to the air a brown color and an acid reaction, due to absorption of oxygen; the absorption of oxygen and change of color take place very rapidly if the solution contains an alkali hydroxide. The aqueous solution of Pyrogallol (1 in 10) reduces solutions of the salts of silver, gold, and mercury even in the cold. When freshly prepared, 1 Cc. of the aqueous solution (1 in 20) is colored brownish-red by a few drops of ferric chloride T.S. and this color is changed to deep bluish-black on the addition of 1 or 2 drops of ammonia water. A bluish-black color is also produced in the aqueous solution of Pyrogallol by freshly prepared ferrous sulphate T.S." *U. S.* According to Rosing of Christiana, it is always partially converted, when sublimed, into metagallie acid, to which probably it owes its acid reaction as generally found in commerce; for when quite pure it has no influence on litmus paper. It is a triatomic phenol, $C_6H_3(OH)_3$, and is therefore, properly speaking, not an acid at all; hence the change in the official title to "Pyrogallol." One of its characteristic properties is its strong affinity for oxygen, in consequence of which it instantly undergoes change by contact with chlorine, iodine, bromine, and the acids which readily yield oxygen. Through the same property it rapidly reduces some of the metallic oxides, and its use in photography is based on this effect exercised on the salts of silver. Though unalterable in the air when quite dry, it is rapidly changed in alkaline solution by the absorption of oxygen, so that it may be used for ascertaining the proportion of this gas in a mixture of gases. By the action of phthalic anhydride upon pyrogallol is formed *gallein*, a dye color much used in calico printing. By the action of glacial acetic acid upon pyrogallol in the presence of zinc chloride is formed *gall-acetophenone*, $CH_3-CO-C_6H_3(OH)_3$, which has been used in medicine as a substitute for pyrogallol.

Uses.—Pyrogallol is an actively irritant substance and in concentrated form even mildly caustic. Taken internally in sufficient dose it is an active destroyer of the red corpuscles of the blood, causing the solution of the hæmoglobin and even altering this constituent into methæmoglobin. The toxic symptoms produced by it are vomiting and purging with collapse, pale or cyanosed lips, the skin often presenting a peculiar greenish hue or sometimes jaundiced; the urine is albuminous and may be brown or black from the presence of hæmoglobin or methæmoglobin. Fatty degenerations and enlargement of the liver, similar to those produced by phosphorus, have been noted by Personne (*C. R. A. S.*, Oct. 1869).

The only use for pyrogallol in medicine is as a stimulant antiseptic in various skin diseases as *lupus* and *psoriasis*. But even for this purpose the remedy is not devoid of danger, as at least two deaths are on record from its external application,¹ and Kuseh (*W. K. W.*, 1901) reports abortion in pregnant women from a ten per cent. ointment.

PYROXYLINUM. U. S., Br.

PYROXYLIN [Soluble Gun Cotton, Colloxylin]

(pý-rōx-y-lī'nūm)

"A product obtained by the action of nitric and sulphuric acids on cotton, and consisting chiefly of cellulose tetranitrate [$C_{12}H_{10}(ONO_2)_4O_8$]. It should be kept in cartons, protected from the light." *U. S.*

Pyroxylin, *U. S.* 1870; Gun Cotton, Collodion Cotton; Pulmicotton soluble, *Fr.*; Kollodiumwolle, *G.*; Piroxylina, *Sp.*

The process of the U. S. P. 1890 for making pyroxylin was not introduced into the U. S. P. (8th Rev.). It is as follows: "Purified Cotton, *one hundred grammes* [or 3 ounces av., 231 grains]; Nitric Acid, *fourteen hundred cubic centimeters* [or 47 fluidounces, 163 minims]; Sulphuric Acid, *twenty-two hundred cubic centimeters* [or 74 fluidounces, 187 minims]; Alcohol, Ether, Water, each, *a sufficient quantity*. Mix the Acids gradually in a glass or porcelain vessel, and, when the temperature of the mixture has fallen to 32° C. (90° F.), add the Purified Cotton. By means of a glass rod imbue it thoroughly with the Acids, and allow it to macerate, until a sample of it, taken out, thoroughly washed with a large quantity of Water, and subsequently with Alcohol, and pressed, is found to be soluble in a mixture of *one volume* of Alcohol and *three volumes* of Ether. Then remove the Cotton from the Acids, transfer it to a larger vessel, and wash it, first, with cold Water, until the washings cease to have an acid taste, and then with boiling Water, until they cease to redden blue litmus paper.

Finally, drain the Pyroxylin on filtering paper, and dry it in small, detached pellets, by means of a water-bath or steam-bath, at a temperature not exceeding 60° C. (140° F.). Keep the Pyroxylin, loosely packed, in well-closed vessels containing not more than about 25 Gm., in a cool and dry place, remote from lights or fire." *U. S.* 1890.

"Cotton, 1 ounce (Imperial) or 10 grammes; Sulphuric Acid, 5 fl. ounces (Imp. meas.) or 50 cubic centimetres; Nitric Acid, 5 fl. ounces (Imp. meas.) or 50 cubic centimetres; Distilled Water, *a sufficient quantity*. Mix the Acids in a porcelain mortar, immerse the Cotton in the mixture, and after it is thoroughly wetted by the Acids stir it for three minutes with a glass rod; wash the product with Distilled Water until free from acid; drain on filtering paper, and dry the Pyroxylin on a water-bath." *Br.*

Gun cotton was discovered by Schönbein of Basel, in Switzerland. The name is applied to several closely related yet distinct products. They are not, as was at first supposed, nitro-derivatives in which the group NO_2 merely replaces hydrogen, atom for atom, but compounds in which the nitric acid residue NO_3 is present, replacing OH groups of the cellulose formula. Thus, taking the doubled formula $C_{12}H_{20}O_{10}$ for cellulose, there is produced by the action of nitric acid under different circumstances $C_{12}H_{14}O_4(NO_3)_6$, and following this, successively, $C_{12}H_{15}O_5(NO_3)_5$, $C_{12}H_{16}O_6(NO_3)_4$, $C_{12}H_{17}O_7(NO_3)_3$, and $C_{12}H_{18}O_8(NO_3)_2$. The first of these, the hexanitrate, is insoluble in alcohol and ether, and constitutes the true explosive gun cotton. The soluble gun cotton used in the preparation of *collodium* is a varying mixture of the four lower nitrates, but is chiefly made up of the tri- and tetra-nitrates. (Tollens, *Handbuch der Kohlenhydrate*, 1888.) The hexanitrate, when very thoroughly washed free from acid, is insoluble in water, alcohol, ether, and all mixtures of alcohol with ether. It constitutes the true explosive gun cotton, which when compressed in cakes and fired by a fulminate explodes with great violence. Other compounds intermediate between some of these have been described by different chemists, but Abel, the chemist of the Woolwich Arsenal in England, has shown that they were imperfectly purified preparations.

Properties.—Gun cotton has the appearance of ordinary cotton, but is harsh to the touch. When intended for solution it is best made by the joint action of sulphuric and nitric acids, or, as proposed by Ellet of the South Carolina College, of potassium nitrate and sulphuric acid. Experience has thoroughly shown that the use of the acids as practised in the 1890 official formula gives better results than the employment of potassium nitrate and sulphuric acid, which was directed in the U. S. P. 1860.²

¹ *Oxidized Pyrogallol* has been used in the treatment of leprosy by Unna. (*M. R.*, 1896, 132.)

² J. G. Flint states that he has often been unsuccessful with the official formula, and recommends the following as perfectly reliable. Place 6 parts by weight of nitric acid in a stone jar, and pour on it 12 parts by weight of sulphuric acid. When the

Care should be exercised not to let the mixture attain a temperature much above 32° C. (90° F.). It is insoluble in water, and nearly so in alcohol, but dissolves freely in acetic ether and amyl acetate. (*A. J. P.*, 1887, 275.) The following are the official description and tests. "A yellowish-white, matted mass of filaments, resembling raw cotton in appearance, harsh to the touch; exceedingly inflammable, burning, when unconfined, very rapidly with a luminous flame; less explosive than cellulose trinitrate. Slowly but completely soluble in 25 parts of a mixture of 3 volumes of ether and 1 volume of alcohol. Soluble in acetone and in glacial acetic acid, and precipitated from these solutions on addition of water. It

temperature has fallen to about 35° C., place the jar in a larger vessel, and surround it with broken ice. After the temperature has fallen to 15° C., take 1 part of absorbent cotton, loosen it well, and place a small portion at a time carefully on the surface of the acid and with a clean glass rod press it below the surface. Keep the thermometer in the acid, and watch the temperature closely. If at any time it rises above 16.5° or 17° C., stop the addition of cotton until the temperature has fallen to 15° C. After five hours, remove the jar from the ice, and drain off as much of the acids as possible, pressing the cotton with the glass rod. Protect the hands with rubber gloves, and take up the cotton in small portions, washing each quickly in cold water, mangle the cotton about to avoid any rise in the temperature. Finally, wring out well, and spread on clean boards to dry. Hot water for the washing must never be used. As to the keeping, the author directs to keep it in an open jar under distilled water. Tightly closed containers will make trouble. The acids may be used several times over. (*West. Drug.*, 1892.)

Soluble Pyroxylin.—E. Senft, from among the many methods proposed for preparing collodion-cotton, selects that of the (German) Military-Pharmacopœia, 1891, for the purpose of exemplifying the precautions necessarily observed to produce a product permanently and uniformly soluble in a mixture of ether and alcohol. Into a mixture of 800 Gm. of crude nitric acid and 2000 Gm. of sulphuric acid 100 Gm. of purified cotton are submerged; the mixture is set aside for 24 hours at a temperature of 15° to 20° C., is then transferred to a funnel, allowed to drain during 24 hours, washed with water until the acid is completely removed, expressed, and dried at a temperature of 25° C. Although this formula is clear and explicit, a number of precautions must be observed to secure a satisfactory product. The mixture of the acids should be effected under avoidance of heat, which is best accomplished by placing the vessel containing the sulphuric acid into cold water and adding the nitric acid slowly. The cotton having then been imbued in the acid mixture, the container is placed in a shady situation, where it is protected both from the light and heat of the sun, and where the temperature will not exceed 20 to 25° C. It is of importance also that the mixture be covered as soon as it is effected. Although in the opinion of Hager and others the prolonged immersion of the cotton in the acid mixture does not affect the solubility of the pyroxylin after it has been formed, the author is of the opinion that under such conditions, as also under the influence of the sun's rays, or of higher temperature than that given, sparingly soluble nitrocelluloses are formed. An exposure of 16 hours during summer is sufficient, while in winter this may be somewhat prolonged. Instead of washing the pyroxylin upon a funnel, it is to be transferred directly from the acid mixture to the water, and well washed—observing that it is necessary to loosen the fibres of pyroxylin which have unavoidably formed into little knots, so that all parts may be completely washed and deprived of acid. So prepared and dried it should dissolve readily and completely if, as is directed for preparing collodion, 100 Gm. are first thoroughly imbued with 300 Gm. of alcohol, and then mixed with 2100 Gm. of purified ether and thoroughly shaken. If a somewhat larger proportion of alcohol is used, an even handsomer preparation is obtainable. (*Ph. Post*, Nov. 5, 1899, 607.)

should leave no weighable residue of mineral impurity when ignited. When kept in well-closed bottles and exposed to the light, it is decomposed with the evolution of nitrous vapors, a carbonaceous mass being deposited." *U. S.* "Readily soluble in a mixture of equal volumes of ether and alcohol (90 per cent.). It leaves no residue after ignition (absence of mineral impurity)." *Br.* Guichard proposes the use of chemically pure filtering paper as yielding a superior product to cotton. He takes 1400 parts of sulphuric acid, sp. gr. 1.82; 700 parts of nitric acid, sp. gr. 1.37; 70 parts of the paper; puts the mixed acid in a vessel surrounded by cold water to keep down the temperature, drops the paper in leaf by leaf, allows it to stand three hours, and then washes freely with water. (*J. P. C.*, 4e sér., xii. 290.) According to J. H. Gladstone of England, gun cotton is subject to spontaneous decomposition if kept for some time. The same fact was observed by James Beatson of New York, and Procter of Philadelphia. The specimen observed by Procter to undergo decomposition had not been well washed. The change is shown by the bottle in which the gun cotton is kept becoming full of nitrous acid vapor, and the substance is so far altered that it is no longer explosive or soluble in ether. Bouet states that the decomposition from exposure to light takes place sooner in gun cotton which has been prepared with potassium nitrate and sulphuric acid than where the mixed acids have been used. He says that, with both, the sides and bottom of the bottle are nearly covered with crystals of oxalic acid. (See *A. J. P.*, March, 1862, p. 187.) The official direction to keep pyroxylin "in cartons, protected from the light" is a valuable precaution against decomposition. According to Béchamp of Strasburg, the product is soluble in ether if the cotton be immersed in a mixture of nitric and sulphuric acid while still hot from their reaction, but not soluble if the cotton be added to the mixture when cold. By treating gun cotton with ferrous chloride, Béchamp caused the disengagement of nitrous oxide gas, and gave the filaments a coating of ferric oxide, which was readily dissolved by hydrochloric acid. After this treatment the gun cotton was restored to its original state of cotton. (*Chem. Gaz.*, Jan. 1, 1854, p. 11.) When kindled, gun cotton flashes off like gunpowder, burning without residue. Yet, according to Bleekrode, when wet with ether, or similar fluid, and touched with a light, the liquid will burn out of it without fring it. (*J. P. C.*, 4e sér., xviii.) Its inflaming point is at 187.7° C. (370° F.). Marx makes it lower. It has been tried as a substitute for gunpowder in fire-arms, etc., but it has not been found useful except for some special purposes. Pyroxylin, or soluble gun cotton, is now extensively used as the basis of transparent varnishes for lacquering metal and wood. The solvent employed is usually a mixture of methyl alcohol or acetone with petroleum benzin, the

miscibility of which is effected by the addition of small quantities of compound ethers like amyl acetate.

Off. Prep.—Collodium, *U. S.*, *Br.*; Collodium Vesicans, *Br.*

QUASSIA. *U. S.* (*Br.*)

QUASSIA

(quâs'si-à)

"The wood of *Picrasma excelsa* (Swartz) Planchon (Fam. *Simarubaceæ*), known commercially as Jamaica Quassia, or of *Quassia amara* Linné (Fam. *Simarubaceæ*), known commercially as Surinam Quassia." *U. S.* "The wood of the trunk and branches of *Pieræna excelsa*, Lindl." *Br.*

Quassia Lignum, Br.; Jamaica Quassia, Quassia Wood; Bitter Wood; Bitter Ash; Quassie Amère ou Bois amer de Surinam, *Fr. Cod.*; Bois de Quassie, Quassie de la Jamaïque, *Fr.*; Lignum Quassia, *P. G.*; Quassiaholz, *Fliegenholz*, *G.*; Quassia, Quassia della Giamaica, *It.*

The *U. S. P.* formerly recognized *Pieræna* as the generic name, but in the Eighth Revision following the authority of Engler and Prantl adopted *Picrasma*. The genus is represented by eight species, which are found in the warmer regions of the Old and New World. They all possess a bitter wood and bark. The one most esteemed is *Picrasma excelsa* (Sw.) Planch., the wood of which furnishes the Jamaica quassia, which is official. The medicine was formerly obtained from *Quassia amara*; but more than twenty years since Lamarek stated that, in consequence of the scarcity of this tree, *Quassia excelsa* had been resorted to as a substitute.

Picrasma excelsa (Swartz), Planchon, Eng. and Prantl.—*Pieræna excelsa*, Lindley, *Flor. Med.* 208; *B. & T.* 57.—*Quassia excelsa*, Willd., *Sp. Plant.* ii. 569.—*Simaruba excelsa*, De Cand., *Prodrom.* i. 733; Hayne, *Darstell. und Beschreib.*, etc., ix. 16.—As its name imports, this is a lofty tree, sometimes attaining the height of not less than one hundred feet, with a straight, smooth tapering trunk, which is often three feet in diameter near its base, and is covered with a smooth, gray bark. The leaves are pinnate, with a naked petiole, and oblong pointed leaflets standing upon short footstalks, in opposite pairs, with a single leaflet at the end. The flowers are small, of a yellowish-green color, and disposed in panicles. They are polygamous and pentandrous. The fruit is a small black drupe. The longitudinal section of the wood exhibits elongated cells containing single crystals of calcium oxalate. The transverse section exhibits medullary rays, mostly two or three cells in width. This species inhabits Jamaica and the Caribbean Islands, where it is called *bitter ash*.

Quassia amara, L., *Sp. Pl.* (1762) 553; Willd., *Sp. Plant.* ii. 567; Woodv., *Med. Bot.* 574, t. 204.—The bitter quassia is a small branching tree or shrub, with alternate leaves,

consisting of two pairs of opposite pinnæ, with an odd one at the end. The leaflets are elliptical, pointed, sessile, smooth, of a deep green color on their upper surface, and paler on the under. The common footstalk is articulated and winged. The flowers, which are hermaphrodite and decandrous, are bright red, and terminate the branches in long racemes. The fruit is a two-celled capsule containing globular seeds. *Quassia amara* is a native of Surinam, and is found in Brazil, Guiana, Colombia, Panama, and the West Indies, as also in some tropical countries of the Old World. Its root, bark, and wood were formerly official. They are excessively bitter, as in fact are all parts of the plant.¹ For a paper on the botanical description and history of *Quassia amara*, by J. U. Lloyd, see *West. Drug.*, 1897, 7.

Properties.—Quassia is at first whitish, but becomes yellow by exposure, and sometimes has blackish spots or markings, due to the presence of the mycelium of a fungus. The two varieties are thus officially described:

"Jamaica Quassia.—Occurring in various forms, usually in chips, raspings, or billets; yellowish-white or pale yellow, and of rather coarse texture; odor slight; taste intensely bitter; medullary rays containing tetragonal prisms or small, arrow-shaped crystals of calcium oxalate. Billets of Jamaica Quassia are usually 12.5 Cm. or more in diameter; in tangential section, the medullary rays are mostly 3 to 5 rows of cells in width.

Surinam Quassia.—Occurring usually in billets not exceeding 7.5 Cm. in diameter; the wood is heavier, harder, and more deeply colored than that of Jamaica Quassia, and the medullary rays in tangential section are mostly 1 or 2 rows of cells in width." *U. S.* Quassia imparts its active properties, with its bitterness and yellow color, to water and alcohol.² Its virtues depend upon a peculiar bitter crystallizable principle, denominated *quassin*, which was first discovered by Wiggers, who assigned it the formula $C_{10}H_{12}O_8$. Quassin is white, opaque, unalterable in the air, inodorous, and of an intense bitterness, which in the solutions of this principle is almost insupportable. The bitterness is pure, and resembles that of the

¹According to A. H. Hills, it is possible to distinguish the wood of Jamaica quassia from that of Surinam quassia (*Quassia amara*) by the fact that in the former the medullary rays are mostly three cells in width, and the cells are irregular in size but offer regular radial walls in tangential sections, while in Surinam quassia the medullary rays are only one cell in width, the cells are nearly uniform in size, and their radial walls wavy in tangential sections.

²**Syrupus Quassia.**—This syrup is used in the preparation of a harmless fly-poison. Macerate, during twenty-four hours, 1000 parts of quassia wood with 5000 parts of water, then boil for half an hour, set aside for twenty-four hours, and press; mix the liquid with 150 parts of molasses, and evaporate to 200 parts. A weaker decoction of quassia does not kill the flies. From this the *Fly Water* or *Fly Plate* is prepared as follows: Mix when needed, and dispense without filtering, 200 parts of syrup of quassia, 50 parts of alcohol, and 750 parts of water. It is used by moistening with the mixture a cloth or filtering paper on a plate.

wood. When heated, quassin melts like a resin. It is but slightly soluble in water, 100 parts, at 54° C. dissolving only 0.45 part, and that slowly. By the addition of salts, especially of those with which it is associated in quassia, its solubility is strikingly increased. It is also but slightly soluble in ether, but is very soluble in alcohol, more so in that liquid hot than cold, and the more so the purer it is. Quassin is perfectly neutral, though both alkalies and acids increase its solubility in water. It is precipitated by tannic acid from its aqueous solution, which is not disturbed by iodine, chlorine, corrosive sublimate, the salts of iron, sugar of lead, or even lead subacetate. Adrian and Moreaux (*A. J. P.*, 1884, p. 98) claim to have purified the quassin to a degree beyond that reached by Wiggers and Christiansen, but give no analyses of it.

Oliveri and Denaro (*A. J. P.*, 1885, p. 29) obtained quassin in a thoroughly pure, crystallized state, and made a complete study of it. They give it the formula $C_{32}H_{44}O_{10}$. It melts at 210° to 211° C., and is very soluble in alcohol, chloroform, and acetic acid, but only sparingly so in ether. Its aqueous solution becomes yellow on exposure to the air, is dextro-rotatory, excessively bitter, and reduces Fehling's solution. When quassin is heated to 90° C. for some hours with diluted sulphuric acid (4 per cent.) it yields *quasside*, $C_{32}H_{42}O_9$, a white, amorphous, bitter substance, formed from quassin by removal of H_2O ; no glucose could be detected in the mother liquors. Bromine forms a derivative which seems to have the formula $C_{32}H_{42}Br_2O_9$. If quassin is heated with concentrated hydrochloric acid in sealed tubes for four hours at 100° C., methyl chloride is formed and a colorless substance deposited, which the authors call *quassic acid*, $C_{32}H_{38}O_6(COOH)_2$. This is far less soluble in alcohol than quassin, and crystallizes in silky needles, which melt at 245° C., and reduce Fehling's solution and ammoniacal silver nitrate in the cold. The authors consider quassin as the methyl ether of this quassic acid, as follows:

The real nature of quassin is at present somewhat doubtful, it being probable that distinct substances have been confounded by chemists. Dymock and Warden believe that they have obtained quassin from the wood of *Picrasma quassoides* (Ham.), Benn., of India. According to the researches of Massute (*A. J. P.*, 1890, p. 338), *Quassia amara* contains four principles, which are different from those of *Picrasma excelsa*. By shaking an alcoholic extract of quassia wood with chloroform he obtained a mixture of crystals, from which, eventually, four bitter principles, differing in melting point and solubility, were separated. One of these melting at 210° to 211° C., and another melting at 239° to 242° C., were in too small a quantity to be further examined, but the former agreed in melting point and crystalline

form with the quassin of Wiggers ($C_{32}H_{44}O_{10}$). Of the other two, one melted at 215° to 217° C., and is represented by the formula $C_{36}H_{48}O_{10}$, while the other melted at 221° to 226° C., and is represented by $C_{37}H_{50}O_{10}$. From the wood of *Picrasma excelsa* two crystalline compounds were separated by Massute, both having lower melting points than either of the compounds from *Q. amara*. One was in needles, melted at 204° C., and had the composition $C_{35}H_{46}O_{10}$, while the other was in prisms, melted at 209° to 212° C., and had the composition $C_{36}H_{48}O_{10}$. Both of these are homologues of a third crystalline principle, $C_{32}H_{44}O_{10}$, melting point 212° to 216° C., which occurs with them. When the *picrasmin*, $C_{36}H_{48}O_{10}$, above referred to, melting at 204° C., is heated with hydrochloric acid, it is changed like quassin into an acid, which in this case has the formula $C_{36}H_{42}O_{10} + 5H_2O$, and is called *picrasmic acid*. It appears, therefore, that each wood represents a different series of homologous compounds.

Uses.—Quassia has in the highest degree all the properties of the simple bitters. It is purely tonic, invigorating the digestive organs, with little excitement of the circulation or increase of animal heat. It has not been very long known as a medicine. About the middle of the last century, a negro of Surinam, named Quassi, acquired considerable reputation in the treatment of the malignant fevers of that country by a secret remedy, which he was induced to disclose to Rolander, a Swede, for a valuable consideration. Specimens were taken to Stockholm by this gentleman in the year 1756, and the medicine soon became popular in Europe. The name of the negro has been perpetuated in the generic title of the plant. But the quassia of Surinam is now comparatively little used, it having been superseded by the product of *Picrasma excelsa* from the West Indies.

Quassia is among the most powerful of the simple bitters, useful in *failure of appetite* due to gastric debility, and in overdoses capable of sufficiently irritating the stomach to produce vomiting. Its active principle, *quassin*, has been studied by Comparden, who asserts that in moderate doses it acts as a stimulant to the salivary, hepatic, and renal secretions, and in overdoses causes burning pain in the œsophagus, with headache, nausea, vertigo, vomiting, diarrhœa, and muscular cramps. It is also stated that if given in doses of six-tenths of a grain (0.04 Gm.) before meals it increases markedly the alvine discharges, and that it is especially useful in *constipation* from debility of the muscular and intestinal coats. The dose of pure quassin is three-tenths of a grain (0.02 Gm.).

Quassia is given in infusion, tincture, extract, or fluidextract, in doses respectively of one-half to one fluidounce (15 to 30 Cc.), one-half to one fluidrachm (1.8 to 3.75 Cc.), one-half to one grain (0.032 to 0.065 Gm.) and five to ten minims (0.3 to 0.6 Cc.). Some *dyspeptic*

patients who have become habituated to its bitterness, chew the wood occasionally with benefit.

Dose, five to ten grains (0.32 to 0.65 Gm.).

QUERCUS. U. S.

WHITE OAK [*Quercus Alba*, Pharm. 1890]

(querc'ūs)

"The dried bark of *Quercus alba* Linné (Fam. *Cupulifera*), collected from trunks or branches ten to twenty-five years of age, and deprived of the periderm." *U. S.*

Stone Oak; Ecorce de Chêne, *Fr. Cod.*; Cortex Quercus, *P. G.*; Eichenrinde, *G.*; Quercia, Cortecchia de quercia, *It.*

This genus comprises numerous species, of which about sixty-five grow within the limits of the United States. Many of these are applied to important practical purposes. In the Northern hemisphere the oak is among the most valuable and the most widely diffused of all forest trees. Notwithstanding the great number of species, few, comparatively, have found a place in the official catalogues. *Quercus Robur*, or European oak, has a very wide distribution. It is the common British oak, constitutes a large part of the European forests, and has spread itself over almost the whole northern section of Asia and along the northern coast of Africa. There are two distinct varieties of it, one, *pedunculata*, with sessile or shortly stalked leaves and the acorns on long peduncles; the other, *sessiflora*, with the leaf-stalks more or less elongated and the acorns either sessile or provided with a very short peduncle. At the late revision of the *Br. Pharm.* the dried bark of the smaller branches and young stems of this tree, *Quercus cortex*, *Br.* 1885, was dismissed from the official list. Our own Pharmacopœia recognizes only *Q. alba*, or white oak. *Q. velutina*, Lam. (*Q. tinctoria*, Bartr.), or black oak, which was formerly official, and various other species, afford actively astringent barks. Such are *Q. digitata* (Marsh.), Sudw. (*Q. falcata*, Michx.), or Spanish oak, and *Q. Prinus*, or white chestnut oak.

Quercus alba, L., *Sp. Pl.* (1753) 996; Willd., *Sp. Plant.* iv. 448; Michaux, *N. Am. Sylva*, i. 17; B. & T. 250.—Of all the American species, the white oak approaches nearest, in the character of its foliage and the properties of its wood and bark, to *Q. pedunculata* of Great Britain. When allowed to expand freely in the open field, it divides at a short distance from the ground into numerous widely spreading branches, and attains under favorable circumstances a magnificent size. Its trunk and large branches are covered with a whitish bark, which serves to distinguish it from most of

the other species. The leaves are regularly and obliquely divided into oblong, obtuse, entire lobes, which are often narrowed at their base. When full grown, they are smooth and light green on their upper surface, and glaucous beneath. Some of the dried leaves remain on the tree during the whole winter. The acorns are large, ovate, contained in rough, shallow, grayish cups, and supported singly or in pairs upon peduncles nearly an inch long.

The white oak abounds in the Middle States, and extends also through the whole Union, though comparatively rare in the northern, southern, and western sections. It is the most highly valued for its timber of all the American oaks, except the live oak, *Q. virginiana*, Mill. (*Q. virens*, Ait.), which is preferred in ship building. The bark is sometimes used for tanning, but the barks of the red and Spanish oaks are preferred. All parts of the tree, with the exception of the epidermis, are more or less astringent, but this property predominates in the fruit and bark.

White oak bark, deprived of its epidermis, is of a light-brown color, of a coarse, fibrous texture, and not easily pulverized. It is officially described as "in nearly flat pieces, 2 to 10 Mm. thick; externally light brown, becoming darker with age, rough-fibrous; fracture uneven, coarsely fibrous; odor distinct; taste strongly astringent; not tingeing the saliva yellow when chewed." *U. S.* The English oak bark was formerly officially described as occurring "in quills covered with a smooth shining silvery or ash-gray variegated with brown corky layer; internally cinnamon-brown or brownish-red and longitudinally striated; fracture tough and fibrous; taste very astringent; no marked odor." Water and alcohol extract the active properties of oak bark. The chief soluble ingredients are tannin, gallic acid, and extractive matter. It is upon the tannin that its medicinal virtues, as well as its use in the preparation of leather, chiefly depend. The proportion of this ingredient varies with the size and age of the tree, the part from which the bark is derived, and even the season when it is gathered. It is most abundant in the young bark, and the English oak is said to yield four times as much in spring as in winter. H. Davy found the inner bark most abundant in tannin, the middle portion or cellular integument much less so, and the epidermis almost wholly destitute as well of this principle as of extractive.

The tannic acid of the oak barks is known as *quercitanic acid*, and has, according to Löwe (*Zeit. An. Chem.*, 20, p. 208), two forms, one soluble in water, of the formula $C_{28}H_{28}O_{14}$, and the other difficultly soluble, $C_{28}H_{24}O_{12}$. Both are changed by the loss of water into oak red, $C_{28}H_{22}O_{11}$. Neither is a glucoside.

Gerber discovered in European oak bark a peculiar bitter principle upon which he conferred the name of *quercim*. It is obtained by boiling the bark with water acidulated with one

hundredth of sulphuric acid, adding first milk of lime until the sulphuric acid is removed, and then a solution of potassium carbonate so long as a white precipitate is produced, filtering the liquor, evaporating to the consistence of a thin extract, adding alcohol, and finally evaporating the spirituous solution down to a small volume, and allowing it to rest for some days. Yellow crystals form, which may be obtained colorless by repeated crystallizations. This quercin Husemann considers to have been only impure quercite (or oak sugar).

Quercus velutina, or black oak, is one of our largest trees, frequently attaining the height of eighty or ninety feet. Its trunk is covered with a deeply furrowed bark, of a black or dark brown color. The leaves are ovate-oblong, pubescent, slightly sinuated with oblong, aculeate lobes. The fructification is biennial. The acorn is globose, flattened at top, and placed in a saucer-shaped cup.

Black oak bark has a more bitter taste than that of the other species, and may be distinguished also by staining the saliva yellow when it is chewed. Its cellular integument contains a coloring principle, capable of being extracted by boiling water, to which it imparts a brownish-yellow color, which is deepened by alkalis and rendered brighter by acids. Under the name of *quercitrin*, large quantities of this bark, deprived of its epidermis and reduced to coarse powder, are sent from the United States to Europe, where it is used for dyeing wool and silk of a yellow color. The coloring principle is called *quercitrin*, and the formula $C_{38}H_{58}O_{50}$, was given to it by Liebermann and Hamburger. Herzig (*J. Chem. S.*, 1893, 413), however, has found that its composition is more correctly expressed by the formula $C_{32}H_{52}O_{12} + 2H_2O$, and in this he is confirmed by Rudolph (*Ph. Post*, 1893, 529). The reaction for its decomposition is

$C_{32}H_{52}O_{12} + H_2O = C_{15}H_{10}O_7 + C_6H_{10}O_6$
the products being *quercetin* and *isodulcetin* in equal molecules.

Quercitrin forms yellowish crystals, which, pulverized, yield a citron-yellow powder. It is neutral in reaction, is odorless, and in the dry condition tasteless, but in hot aqueous or alcoholic solution has a bitter taste. It fuses at 160° to 200° C. to a resinous mass. It is almost insoluble in cold water, sparingly soluble in hot water, and easily soluble in alcohol and alkaline solution.¹ Besides this principle, the

bark contains much *quercitanic acid*; but it is less used in tanning than the other barks, in consequence of the color which it imparts to the leather, and it was dropped from the U. S. P. 1890 on account of its decoction staining so decidedly.

Uses.—Oak bark is astringent and somewhat tonic; but it is not employed as an internal remedy. On account of its cheapness it is much used externally. The decoction may be advantageously used as a bath, particularly for children, when a combined tonic and astringent effect is desirable and the stomach is not disposed to receive medicines kindly. It has been employed in this way in *marasmus*, *scrofula*, *intermittent fevers*, *chronic diarrhoea*, and *cholera infantum*. As an injection in *leucorrhoea*, a wash in *prolapsus ani* and *hemorrhoidal affections*, and a gargle in *prolapsed uvula*, the decoction is often useful, and the infusion obtained from tanners' vats has been employed beneficially as a wash for *flabby, ill-conditioned ulcers*.

QUILLAJA. U. S. (Br.)

QUILLAJA [Soap Bark]

(quíl-lá'ja)

"The dried bark of *Quillaja Saponaria* Molina (Fam. *Rosaceæ*), deprived of the periderm." U. S. "The inner part of the bark of *Quillaja saponaria*, Molina." Br.

Quillaia Cortex, Br.; Quillaja Bark; Quillaja, Pharm. 1880; Panama Bark; Panama (Bois de), Fr. Cod.; Ecorce de Quillaja, Fr.; Seifenrinde, G.

The name of this genus is said to be derived from the popular name of the tree *Quillay*, which in turn comes from the Chilean word *quillean*, to wash.

Quillaja Saponaria, Molina.—This is a tree of moderate size, with alternate oval or oblong leaves, with entire or slightly denticulate margins. Male and female flowers grow on the same branch, are axillary, pedunculate, and without corolla. The calyx of the female flower persists in fruit, and has its limb deeply divided into five oval acute segments. The bark is thick, the wood very hard.² The tree is a native of Peru and Chili, but is now cultivated in Northern Hindostan, where it is said to resist well the frosts of winter, and to be flourishing.

¹ Quercitrin has been found also in various other plants, as in the leaves of *Ruta graveolens*, and the flower buds of *Capparis spinosa*, *Sophora japonica*, and *Æsculus Hippocastanum*, or horse chestnut. (*Chem. Gaz.*, May 2, 1859, p. 161.) As this principle is capable of assuming various colors under various chemical influences, the idea has been advanced that it might be the coloring principle of flowers. (*A. J. P.*, 1860, 222.)

² Acorns, besides the bitter and astringent principles of the bark, contain a peculiar saccharine matter (*quercite*), which is insusceptible of the vinous fermentation. (*J. P. C.*, 3e sér., xx. 335.) They are sometimes used as a tonic or astringent, and a decoction made from roasted acorns has been long employed in Germany as a remedy in *scrofula*. Be-

fore roasting they should be deprived of their shells, and the cotyledons, according to Dausse, should lose, during the process, 28 per cent. of their weight (*Ph. Ch.*, Oct. 9, 1850, p. 687). From half an ounce to an ounce may be prepared and taken like coffee at breakfast. (Richter.)

³ This tree was first described by the famous Abbé Giovanni Ignazio Molina in the *Saggio sulla Storia naturale del Chili*, published at Bologna, in 1782; second edition, 1810. (Translated into German, I. D. Brandis, Leipzig, 1786; into French, Gravel, Paris, 1789; into English, London, 1800; also Middletown, Conn., 1880.) It is first noticed by systematic writers in the second (Gmelin's) edition of the *Syst. Nat.*, tome ii. p. 767.

Properties.—Soap bark is officially described as "in flat pieces of variable length, 3 to 8 Mm. thick, or in small chips; outer surface brownish-white, often with small patches of cork attached, otherwise nearly smooth; inner surface yellowish-white, nearly smooth, with occasional circular depressions, conical projections or transverse channels; fracture uneven and strongly fibrous, the laminae oblique to each other; odor slight; taste acrid. The powder is strongly sternutatory, and contains calcium oxalate in monoclinic pyramids and prisms from 0.035 to 0.200 Mm. long." *U. S.* The fracture exhibits, when slightly magnified, glistening prismatic crystals. A transverse section is marked with fine radial and tangential lines. (Mitlacher, *P. P.*, 1902.) Quillaja bark is histologically distinguished and its powder recognizable, by the large and numerous prismatic calcium oxalate crystals, especially by the irregular bast fibres which are colored pale red by diluted sulphuric acid or hydrochloric acid, probably on account of the presence of phloroglucin.

When bruised and macerated in water quillaja bark imparts to that liquid the property of frothing like soap when agitated. This has been found by Fleury, Jr., and Boutron-Chalard to be owing to the existence of *saponin* in the bark, the same principle as that which gives a similar property to *Saponaria officinalis*. (See PART II.) The bark contains neither tannic acid nor any bitter principle. The formula of saponin, given by Rochleder, was $C_{52}H_{64}O_{18}$, and Schiaparelli agreed with him. Stütz, however (*Ann. Ch. Ph.*, 218, 231), gives it as $C_{19}H_{30}O_{10}$, and this is now accepted for the saponin of quillaja bark. Saponin is slowly decomposed by dilute acids into *sapogenin*, $C_{14}H_{22}O_8$, and a glucose. R. Kobert (*Chem. Central.*, 1893, i. 32) gives a list of one hundred and forty plants which contain bodies of the saponin class. He arranges them under several formulas which seem to form an homologous series. Thus, $C_{17}H_{26}O_{10}$ he terms Saponin I (*senegin* or *quillaia sapotoxin*); $C_{18}H_{28}O_{10}$ is Saponin II (Schmiedeberg's *digitonin* or *saporubrin*); $C_{19}H_{30}O_{10}$ is Saponin III (*quillain* or *quillaia acid*); $C_{20}H_{32}O_{10}$ is *cyclamin*, Paschki's *digitoxin*, or *sarsaparilla-saponin*; $C_{22}H_{36}O_{10}$ is *sarsa-saponin*; $C_{26}H_{44}O_{10}$ is *parillin*.

Saponin, as found in commerce, is a powerful poison. Kobert states, however, that *pure* saponin, $C_{19}H_{30}O_{10}$, is destitute of physiological action, and that commercial saponin depends for its activity mainly upon *quillaia acid* and *sapotoxin*, the other substances present being saponin and *lactosin*, $C_{36}H_{62}O_{31}$. G. Mel-liers states that there is present in quillaja bark a carbohydrate which he has identified as *saccharose*. (*P. J.*, Feb. 1901, 161.)

Uses.—Both the active principles, quillaia acid and sapotoxin, of quillaja bark are violent local irritants. In a case of poisoning by quillaia acid (*T. G.*, xi.) the symptoms were violent vomiting, with epigastric pain, increased

diuresis and cystic irritation, accompanied by cold sweats, feeble pulse, threatened syncope, and other evidences of collapse.

Sapotoxin, when in sufficient concentration and amount, is a fatal poison to all forms of protoplasm. Given to the lower animals in very large toxic dose it produces violent convulsions with death from failure of the respiration. When in smaller quantities it causes violent dysenteric diarrhoea, with ecchymotic hyperæmia, œdema, and necrotic destruction of the intestinal mucous membrane. The smallest lethal doses are said to produce great weakness, death occurring after some days through collapse and general paralysis without intestinal symptoms. In such cases, when the drug is administered hypodermically, a severe hemorrhagic inflammation occurs at the place of injection. Fatty preparations of sapotoxin applied to the sound skin produce redness and burning with, after repeated applications, painful pustulation. Both sapotoxin and quillaia acid have the power of breaking down the red blood corpuscles, but it is not apparent that such destruction plays an important rôle in poisoning by these substances except at the point of injection after hypodermic use.

On account of the active principles of soap bark being the same as those of senega, and to some extent of sarsaparilla, Kobert has proposed the use of quillaja as a cheap substitute for these much used drugs. As a stimulating expectorant he uses a decoction (five parts to two hundred) in doses of a tablespoonful for the adult. As a substitute for syrup of senega Power suggests the *syrup of quillaja*, prepared by adding four parts of the fluidextract (made by the process for fluidextract of arnica root, see p. 524) to sufficient syrup to make twenty-five parts. (*P. J.*, Oct. 1886.)

Quillaja is much used in the arts for washing silk, cloth, and other fabrics, for which soap would not be suitable. It is an emulsifying agent, but unless ordered by the physician should never be used by the pharmacist in the preparation of emulsions, on account of its active medicinal properties.

Off. Prep.—Fluidextractum Quillajæ, *U. S.*; Liquor Picis Carbonis, *Br.*; Tinctura Quillajæ, *U. S.* (*Br.*).

QUININA. U. S.

QUININE

(quī-nī'nā)

"An alkaloid obtained from the bark of various species of *Cinchona* (Fam. *Rubiaceæ*). Quinine should be kept in well-stoppered, amber-colored bottles." *U. S.*

Chininum; Quinine Hydratée, *Fr. Cod.*; Chinin, *G.*; Chinina, *It.*; Quinina, *Sp.*

This alkaloid is prepared by adding to a solution of quinine sulphate a quantity of ammonia

water or solution of sodium hydroxide just a sufficient quantity to cause a precipitation of the alkaloid.

Properties.—Quinine is whitish, rather flocculent, and usually not crystalline; it may with care be crystallized from its alcoholic solution in silky needles, and Liebig obtained it from a somewhat ammoniacal aqueous solution in the same form. It is inodorous and very bitter. The crystals obtained from alcoholic solution have the composition $C_{20}H_{24}N_2O_2 + 3H_2O$, and fuse at $57^\circ C.$ ($134.6^\circ F.$). They may be deprived of water by warming or exposure over sulphuric acid, and they then fuse at 171.2° to $172^\circ C.$ (340° to $341.6^\circ F.$). By carefully regulated heat, it may be sublimed unchanged, assuming a crystalline form. (Waddington, *P. J.*, March, 1868, p. 413.) According to Hesse, anhydrous crystalline quinine is soluble in 1960 parts of water at $15^\circ C.$ ($59^\circ F.$), and the trihydrate in 1670 parts. It is soluble in about 900 parts of boiling water, in about 6 parts of cold and in 2 parts of boiling alcohol, very soluble in ether, chloroform, benzene, petroleum benzin, carbon disulphide, fixed and volatile oils, and in about 200 parts of glycerin. The alcoholic solution is intensely bitter. Quinine is unalterable in the air. It forms salts with the acids which readily crystallize. The tannate, tartrate, and oxalate are said to be insoluble or nearly so, but are dissolved by an excess of acid. The acetate is so slightly soluble that it is precipitated from a solution of the sulphate by magnesium acetate and the other acetates. (*A. J. P.*, xxx. 386.) When recently precipitated quinine, diffused in water, is exposed to the action of a stream of carbon dioxide, the quinine is dissolved, and, if the solution be exposed, acicular crystals of quinine carbonate will be deposited, which effloresce in the air, are soluble in alcohol, but insoluble in ether, have an alkaline reaction, and effervesce with acids. After the deposition of the crystals has ceased, the solution yields quinine on evaporation. (Langlois, *C. R. A. S.*, Nov. 7, 1853, 727.) Freshly precipitated quinine is scarcely soluble to an appreciable extent in an excess of potassium hydroxide, but is more readily dissolved by ammonia. (Wadgymar, *A. J. P.*, Sept. 1866, 451.) Flückiger (1878) noticed that solutions of quinine exposed to sunlight rapidly turned brownish-yellow, and subsequently deposited a flocculent precipitate, which he proved to be neither quinine nor quinine, but an entirely different substance. It lost the alkaloidal character, yet possessed the same chemical composition as quinine. He named it *quiniretin*. (*P. J.*, May, 1878.)

Quinine and its salts may be distinguished from all other alkaloids and their salts, except only quinidine and quinicine, by the beautiful emerald-green color (*thalleioquin*) which results when their solution is treated first with solution of chlorine and then with ammonia, and which changes to a white or violet upon saturation with a dilute acid. The statement which has been

frequently made that the chlorine water must be fresh, was disproved by C. F. Zeller. (See *A. J. P.*, 1880, p. 385.) The least quantity of quinine may be detected by powdering the substance supposed to contain it, then shaking it with ether, and adding successively the tests just mentioned. Quinine in aqueous solution turns the plane of polarization to the left, to varying degrees, however, according to the concentration, the solvent used, etc. Acids increase the amount of deviation. In relation to the property possessed by quinine of imparting fluorescence to its aqueous solution, which is possessed also, though in less degree, by other cinchona alkaloids, and other properties common to both quinine and its sulphate, there will be occasion to speak under quinine sulphate. A singular discovery was made by Bence Jones of London, of a substance normally present in the animal system having analogous properties, and named by him "*ammal quinoidine*."

Quinine is officially described as "a white, flaky or micro-crystalline powder, odorless, having a bitter taste, and slightly efflorescent in dry air. Quinine, when freshly crystallized, should contain three molecules of water of crystallization. When heated, it fuses at $57^\circ C.$ ($134.6^\circ F.$), and loses two molecules of water of crystallization at $100^\circ C.$ ($212^\circ F.$), and the third molecule at $125^\circ C.$ ($257^\circ F.$); at ordinary temperatures the loss is gradual. Quinine free from water is soluble in 1750 parts of water, 0.6 part of alcohol, 4.5 parts of ether, 1.9 parts of chloroform, 158 parts of glycerin, 120 parts of benzene, 3450 parts of a solution of potassium hydroxide (1 in 20), and in 1810 parts of ammonia water at $25^\circ C.$ ($77^\circ F.$). It is soluble in 810 parts of water at $80^\circ C.$ ($176^\circ F.$). Quinine containing three molecules of water is soluble in 1550 parts of water, 0.6 part of alcohol, 1.3 parts of ether, 1.6 parts of chloroform, 212 parts of glycerin, 166 parts of benzene, 3450 parts of a solution of potassium hydroxide (1 in 20), and in 1810 parts of ammonia water at $25^\circ C.$ ($77^\circ F.$). It is soluble in 775 parts of water at $80^\circ C.$ ($176^\circ F.$). When rendered anhydrous by heating to constant weight at $125^\circ C.$ ($257^\circ F.$), its melting point is $174.9^\circ C.$ ($346.8^\circ F.$). Its aqueous solution is lævogyrate, and is alkaline to moistened litmus paper. If to 1 Cc. of an aqueous solution of quinine (1 in 100), containing just sufficient diluted sulphuric acid to effect complete solution, there be added 2 Cc. of bromine T.S., followed by 1 Cc. of ammonia water, the liquid should acquire an emerald-green color (*thalleioquin*). If 0.7 Gm. of Quinine be dissolved in a mixture of 15 Cc. of acetic acid, 6 Cc. of alcohol, and 0.5 Cc. of sulphuric acid, the solution heated to boiling, and 7 Cc. of a saturated solution of iodine in alcohol be added slowly, bronze or olive-green crystals of quinine iodo-sulphate will separate on gradually cooling the solution. These crystals are insoluble in cold water. If 0.2 Gm. of Quinine be dissolved in 1 Cc. of diluted sulphuric acid, the solution diluted with

distilled water to 20 Cc. and neutralized with ammonia water, and 1 drop of solution of hydrogen dioxide and 1 drop of copper sulphate T.S. be added, and the liquid boiled, an intensely red color should appear, which slowly changes to a blue, and finally to a green color. (Quinine and quinidine alone respond to this test.) One Gm. of Quinine should dissolve completely in a slightly warmed mixture of 6 Cc. of absolute alcohol and 3 Cc. of ether, which solution should remain clear on cooling (absence of *cinchonine* and *cinchonidine*). Quinine should not impart more than a faintly yellowish tint to sulphuric acid (limit of *readily carbonizable organic impurities*), nor produce a red color with nitric acid (difference from *morphine*). Quinine should not lose more than 14.3 percent. of water on heating to 125° C. (257° F.) (absence of an excess of water). When heated with 2 Cc. of potassium hydroxide T.S., no ammonia should be evolved (absence of *ammonium salts*). Dissolve 2 Gm. of Quinine, which has previously been dried at 50° C. (122° F.) for two hours in a porcelain dish, in 20 Cc. of alcohol. Add 2 drops of hematoxylin T.S., neutralize exactly with sulphuric acid, and evaporate to dryness on a water-bath. Complete the test by following the directions given on page 1046, under *Quinnæ Sulphas* (Test for Other Cinchona Alkaloids, Section II.)" U. S.

Quinicine (quinicia).—When quinine and cinchonine, or quinidine and cinchonidine, or their salts, are exposed to heat, they are changed into other but isomeric alkaloids,—quinine and quinidine into *quinicine*, isomeric with themselves, and cinchonine and cinchonidine into *cinchonine*, isomeric with its own antecedents. These new alkaloids are, therefore, products rather than educts, and generally result, in greater or less proportion, from the processes employed in extracting the other alkaloids from bark, though it is not impossible that they may pre-exist in bark to a certain extent, being formed by a natural process, from the same original alka-

loids, either in the living tree, or in the barks while drying, after separation from the tree. *Quinicine* is almost insoluble in water, but very soluble in alcohol, and differs from quinine in being dextro-rotatory and uncrystallizable. *Cinchonine* is also insoluble in water and soluble in alcohol. It agrees with cinchonine, from which it is derived, in producing deviation of the plane of polarization to the right, but differs from cinchonidine in this respect, and differs from both in being amorphous or uncrystallizable.

The study of the decomposition products of quinine and associated alkaloids so actively carried on for several years past has thrown considerable light upon its composition. It appears to be a derivative of a partially hydrogenized diquinoline, corresponding to the formula $C_6H_5(OCH_3)N - C_6H_{11}(OH)N.CH_3$. By oxidation with chromic acid it yields *quininic acid*, $C_6H_5(OCH_3)N.COOH$, which is the phenol ester of cinchoninic acid, $C_6H_5N.COOH$; by oxidation with nitric acid it yields *cinchomeronic acid*, $C_6H_5N(COOH)_2$; by the action of potassium hydroxide it yields *methoxyquinoline*, $C_6H_5N(COCH_3)$. For a summary of our knowledge upon the constitution of quinine and cinchonine, see *Guareschi's Einführung in das Studium der Alkaloide*, translated by H. Hermann Kunz-Krause, Berlin, 1896, 524 *et seq.*

The most important artificial salt of quinine is the *sulphate*, the process for procuring which, as well as its properties, will be hereafter described. The *bisulphate*, *hydrobromide*, and *hydrochloride* have been retained in the U. S. Pharmacopœia, the *valerianate* having been dismissed. The *phosphate*, *acetate*, *citrate*, *lactate*, *camphorate*, *ferrocyanate*, *tannate*, *arsenite*, *antimonate*, *urate*, *hypophosphite*, *chlorate*, *hydrochloride with urea*, *citro-thymate*, *sulphovinate*, *salicylate*, *sulpho-salicylate*, and *meconate*, have also been employed or recommended, but none of them has yet gained admittance into the Pharmacopœias, and none probably is superior to the official sulphate.¹ The first four may be

¹ *Percentage of Quinine in its Different Salts.*—According to Tanret, the salts of quinine in common use contain the following proportions of the alkaloid: acetate, 87.34 per cent.; hydrate (quinine precipitated and dried), 85.70; basic hydrochloride, 81.60; lactate, 78.26; basic hydrobromide, 76.60; valerate, 76.05; basic sulphate (the ordinary sulphate), 74.30; sulphovinate, 72.00; neutral hydrobromide, 60.00; neutral sulphate (or acid sulphate), 57.24; tannate, 20.60. The following table was compiled by Boymond of Paris:

Salts.	Percentage of			1 part soluble in water at 15° C.	1 part of water dissolves		1 part anhydrous quinine contained in
	Alkaloid.	Acid.	Water of crystallization.		Salt.	Anhydrous quinine.	
Hydroxide	85.72	.. .	14.28	16.70	0.00059	0.00050	1.16

prepared by saturating a solution of the acids respectively with quinine, and evaporating the solutions. The *camphorate* is recommended as a substitute for the *valerate*. (*A. J. P.*, July, 1865, p. 254.) The *ferrocyanide* is directed to be made by boiling together four parts of quinine sulphate and one of potassium ferrocyanide, both in concentrated solutions, pouring off the liquor from a greenish-yellow substance of an oily consistence which is precipitated, washing the latter with distilled water, then dissolving it in strong alcohol at 37.7° C. (100° F.), filtering immediately, and afterwards evaporating the solution. Pelouze believes this preparation to be pure quinine, mixed with a little Prussian blue. (*A. G. M.*, 3e sér., xv, 236.) The *tannate* may be prepared by precipitating one part of quinine sulphate, dissolved in thirty parts of water acidulated with a few drops of sulphuric acid, with a solution of three parts of tannic acid dissolved in thirty parts of cold water, and then washing and drying the precipitate. For other methods of preparing the tannate, see *West. Drug.*, 1893, 352; *Ph. Centralh.*, 1894, 155; *Proc. A. Ph. A.*, 1894, 675. It has the advantage of possessing little taste, but doubts have been repeatedly expressed about its efficiency. At best, it is a feeble preparation, containing, as found in commerce, from 22.6 to 32 per cent. of quinine. *Quinine arsenite* has been recommended by Ringdon, especially in chronic cutaneous affections. Adler prepares it by dissolving arsenic trioxide in water, with enough alkali to make the solution neutral, adding about five times its weight of silver nitrate, washing the precipitated silver arsenite, drying, and mixing with three times its weight of quinine hydrochloride, digesting the mixture for a day with 70 per cent. alcohol, filtering, and allowing the filtrate to evaporate spontaneously. The salt is crystalline, soluble in alcohol, chloroform, and ether, but sparingly so in water. The dose is one-third of a grain (0.021 Gm.), given at first twice a day, and afterwards three or four times a day. *Quinine antimonate* has been recommended by La Camera of Naples, as a febrifuge, being especially applicable to cases of doubtful periodicity. It unites, he thinks, the evacuant properties of the antimonials with the antiperiodic property of quinine. The dose is two or three grains (0.13 or 0.20 Gm.), four times a day. (*J. P. C.*, 3e sér., xxv, 471.) *Quinine urate* is thought by Pérayre of Bordeaux, to be peculiarly efficacious in obstinate intermittents. It is prepared by boiling 10 parts of crude quinine in water, adding gradually 20 parts of crystallized uric acid, and, after sufficient ebullition, filtering and evaporating. A yellow salt is obtained, sometimes amorphous, more frequently crystalline, soluble in hot and less so in cold water, and, according to the author, capable of curing intermittent fever in smaller doses than the sulphate, with less cerebral disturbance, less bitterness, and easier tolerance by the stomach. (*J. P. C.*, 3e sér., xxxvii, 139.) *Quinine hypo-*

phosphite may be prepared by dissolving 3 parts of calcium hypophosphite in 60 parts of distilled water, and adding the filtered solution to a solution of 13 parts of quinine sulphate in 200 parts of alcohol, allowing the mixture to stand two hours, and filtering, distilling off the alcohol and evaporating the solution and setting aside to crystallize. The salt is soluble in 25 parts of cold water, in 1.5 parts of boiling water, and in 10 parts of alcohol. *Quinine glycerophosphate* exists in two conditions, basic and neutral. The basic salt, which is stable, may be made by dissolving 75.6 Gm. of quinine in 500 Cc. of ether and mixing with a solution of 17.2 Gm. of glycerophosphoric acid in 60 Gm. of alcohol (95 per cent.), collecting the white precipitate, washing with ether, and drying. (*E. Fallieres, P. J.*, 1898, 410.)

Quinine and urea hydrochloride,—"chininum bimiraticum carbamidatum,"—discovered by Kutais (1878), is best prepared by Rice's process. 79 parts of quinine hydrochloride are dissolved in 70 parts of hydrochloric acid (sp. gr. 1.050), the solution filtered, 12 parts of urea added, and the whole warmed until the liquid is clear. It is then set aside, that crystals may form. These are soluble in an equal weight of water, and also in strong alcohol. This salt has been recommended especially for hypodermic uses. *Quinine citrothymate* is prepared by Pavesi by heating in a flask on a water bath 4 parts of quinine and 6 parts of oil of thyme, with enough alcohol to dissolve both. After standing 12 hours, 2 parts of powdered citric acid are added, and the whole heated, filtered, evaporated, and allowed to crystallize.¹ For uses of quinine see *Quinina Sulphas*.

¹ *Quinine Chlorate* is best prepared, according to C. R. C. Tichborne, from barium chlorate. He mixes in a porcelain dish 310 grains of barium chlorate dissolved in a little boiling water with 2 ounces avoirdupois of quinine sulphate, and 12 ounces of hot water, at 90° C. (194° F.), a slight excess of the sulphate being used to insure the precipitation of all the barium. Owing to this excess, a slight pellicle of quinine sulphate floats on the surface. Apply heat, and gradually add a very little precipitated barium carbonate until the coating of sulphate is replaced by a slightly oily pellicle of alkaloid. The quinine chlorate is now obtained by evaporation and crystallization. For a mode of preparing the barium chlorate, see *A. J. P.*, 1868, p. 101.

The chlorate crystallizes from its solution in fungoid tufts, consisting of filiform, snow-white crystals, radiating from a centre. It melts with heat, and in the air at length takes fire, burning vividly and if dry sometimes with explosion, leaving a carbonaceous residue. It is very soluble in boiling water, but sparingly in cold, and is deposited from its hot solution on cooling. Gently warmed with hydrochloric acid, it emits chlorine copiously and ammonia now added in excess occasions an emerald-green color—thus showing that it is a compound of chloric acid and quinine. (*P. J.*, 2d ser., viii, 135.)

Quinine Citrate.—Quinine, pure, 15 parts; citric acid, 8 parts. The product corresponds to 20 parts of true quinine citrate.

Quinine Hydrobromide.—Quinine sulphate, 100 parts; potassium bromide, 28 parts. The product corresponds to 100 parts of quinine hydrobromide. Quinine hydrobromide contains almost as much quinine as the sulphate, and is soluble in 54 parts of water. It has been extensively used hypodermically in the form of a ten per cent. solution in a mixture of 25 parts of alcohol and 75 parts of water. Its simple aqueous solution seems to be preferable.

Dose, one to five grains (0.065 to 0.32 Gm.).

Off. Prep.—Elixir Ferri, Quininæ et Strychninæ Phosphatum, *U. S.*; Glyceritum Ferri, Quininæ et Strychninæ Phosphatum, *U. S.*; Oleatum Quininæ, *U. S.*; Syrupus Hypophosphitum Compositus, *U. S.*

Quinine Hydriodide.—Quinine sulphate, 95 parts; potassium iodide, 40 parts. The product corresponds to 100 parts of quinine hydriodide.

Iodized Quinine Hydriodide.—Quinine hydrochloride, 70 parts; potassium iodide, 50 parts; iodine, 20 parts. To be triturated together with a little alcohol. Corresponds to 100 parts of the above quinine salt.

Quinine Hypophosphite.—Quinine hydrochloride, 100 parts; calcium hypophosphite, 24 parts. Corresponds to 100 parts of the above quinine salt.

Quinine Lactate.—Quinine, pure, 70 parts; lactic acid, 35 parts. To be triturated together, if necessary, with a few drops of alcohol. Corresponds to 100 parts of the above quinine salt.

Quinine Phosphate.—Quinine sulphate, 94 parts; sodium phosphate, 80 parts. Corresponds to 100 parts of the above quinine salt. (*J. P. C.*, May, 1879; *N. R.*, Nov. 1879.)

Quinine Sulphovinate, according to Carles, is prepared by dissolving 16.9 parts of sodium sulphovinate in 200 parts of hot alcohol, and 42.8 parts of quinine sulphate in 600 parts of hot alcohol. The hot solutions are mixed, cooled, and the precipitated sodium sulphate filtered out. The filtrate is distilled, and the residue evaporated and dried at a low temperature. It is soluble in 3 parts of water. Jaillari has extensively employed hypodermic injections of one part of quinine sulphovinate in nine parts of distilled water, with great satisfaction, in the severe malarial fevers of Algiers.

Quinine Salicylate may be prepared by Jobst's process, by double decomposition between solutions of quinine hydrochloride and ammonium salicylate, or by saturating an alcoholic solution of quinine with an alcoholic solution of salicylic acid. The crystals are soluble in 225 parts of water and in 20 parts of alcohol.

Quinine Phenate, or *carbolate*, is obtained by Jobst, having the composition $C_{20}H_{24}N_2O_8 \cdot C_6H_5O$. It is soluble in 400 parts of water, and in 80 parts of alcohol. (*P. J.*, June 12, 1875.) *Quinine sulphosalicylate*, on account of its slow solubility in water, will probably not be very useful medicinally. (See *N. R.*, 1878, p. 103.) *Quinine meconate* is prepared by mixing alcoholic solution of meconic acid and quinine.

Quinine Valerate. *Quininæ Valerianas.* *Quinine Valerianate.*—"Quinine Valerianate should be kept in well-stoppered bottles in a dark place." *U. S.*, 1890.

"Take of Valerianic Acid half a troyounce; Sulphate of Quinia two troyounces; Diluted Sulphuric Acid, Water of Ammonia, Water, each a sufficient quantity. Dissolve the Sulphate of Quinia in a pint of Water, with the aid of Diluted Sulphuric Acid; then add Water of Ammonia in slight excess, and wash the precipitated quinia with water until freed from sulphate of ammonium. Dissolve the Valerianic Acid in five pints of Water, heated to 180° F., add the quinia to the solution, and, when it is dissolved, set the whole aside for several days to crystallize. Decant the mother-water from the crystals, dry them on bibulous paper, and keep them in a well-stoppered bottle. By evaporating the mother-water at a temperature not exceeding 120° F., more crystals may be obtained." *U. S.*, 1870.

In the process of the *U. S. P.* 1870 quinine is first obtained by decomposing quinine sulphate by means of ammonia, and then combined directly with valerianic acid, to form quinine valerianate, which crystallizes from the solution when it cools, because much less soluble in cold than in hot water. By the late Dublin formula, which, with the salt itself, has been omitted in the British Pharmacopœia, the valerianate was obtained by double decomposition between quinine hydrochloride and sodium valerianate, resulting in the production of sodium chloride, which remained in solution, and quinine valerianate, which crystallized. The modern name for this salt is quinine valerate, the *U. S. P.* (8th Rev.) having adopted the word "valeric" instead of "valerianic" for the acid.

Quinine valerianate is in "white, or nearly white, pearly, lustrous, triclinic crystals, having a slight odor of valerianic acid, and a bitter taste. Permanent in the air. Soluble, at 15° C. (59° F.), in 100 parts of water, and in 5 parts of alcohol; in 40 parts of

QUININÆ BISULPHAS. U. S.

QUININE BISULPHATE

(qui-ni'næ bi-sul'phās)

"The acid sulphate [$SO_2(OH)_2 \cdot C_{20}H_{24}N_2O_2 + 7H_2O$] of the alkaloid quinine. It should be kept in well-stoppered, dark amber-colored vials." *U. S.*

Chininum Bisulfuricum, Quininæ Sulphas Acidus; Acid Quinine Sulphate; Sulfate de Quinine Neutre, *Fr. Cod.*; Saures Chininsulfat, Chininbisulfat, *G.*; Bisolfato di chinina, *It.*; Sulfato quínico neutro, *Sp.*

This salt is made by suspending 100 Gm. of quinine sulphate in 500 Gm. of warm distilled water, and adding 115 Gm. of diluted sulphuric acid (*U. S. P.*), filtering and crystallizing. It has been introduced because of the great advantages in solubility that it possesses over the ordinary sulphate. It requires but 8.5 parts of water to dissolve it, while the sulphate requires 720. For use in the form of pills it is greatly superior on this account, while it may be administered in solution without the excess of acid which must be used when the ordinary sulphate is prescribed in order to dissolve it. Its use is rapidly extending, and when these very important practical points of superiority are fully appreciated by the profession it should be used almost exclusively. It is officially described as in "colorless, transparent or whitish, orthorhombic crystals or small needles; odorless, and having a very bitter taste. It effervesces on exposure to the air, and turns yellow on exposure to the light. Soluble in 8.5 parts of water, 18 parts of alcohol, 1770 parts of ether, 920 parts of chloroform, and in 18 parts of glycerin at 25° C. (77° F.); soluble in 0.68 part of water at 80° C. (176° F.), and in 0.5 part of alcohol at 60° C. (140° F.). When heated, this salt softens at 60° C. (140° F.), becomes semi-fluid at 70° C. (158° F.), and melts at about 160° C.

boiling water, and in 1 part of boiling alcohol. When heated to about 90° C. (194° F.), the salt melts, forming a colorless liquid. At 100° C. (212° F.), it loses its water of crystallization, and also begins to lose valerianic acid. On ignition, it is slowly consumed, leaving no residue. The aqueous solution of the salt is neutral or slightly alkaline to litmus paper. The aqueous solution, when acidulated with sulphuric acid, exhibits a blue fluorescence, and emits the odor of valerianic acid. On treating 10 Cc. of an aqueous solution (about 1 in 1300) of the salt with 2 drops of bromine water, and then with an excess of ammonia water, the liquid will acquire an emerald-green color. With proper adjustment of the reagents, more dilute solutions will give a paler tint, while more concentrated ones will acquire a deeper color, or throw down a green precipitate. Ammonia water added to the aqueous solution throws down a white precipitate, soluble in an excess of ammonia water, and also in about 20 times its weight of ether. Quinine Valerianate should not impart more than a faintly yellowish tint to concentrated sulphuric acid (limit of readily carbonizable, organic impurities). The aqueous solution of the salt should not be rendered more than slightly turbid by barium chloride test-solution (limit of sulphate)." *U. S.*, 1890.

This substance probably does not differ in its general medicinal action from more ordinary salts of the alkaloid, but has been thought to be efficacious in *hemiparesis*.

Dose, two to fifteen grains (0.13 to 1.0 Gm.).

(320° F.), with decomposition. It loses all of its water of crystallization at 100° C. (212° F.). On ignition, the salt is slowly consumed, leaving no residue. Its aqueous solution has a strongly acid reaction and shows a blue fluorescence. Barium chloride T.S. produces a white precipitate, insoluble in hydrochloric acid. If 1 Gm. of the salt be dried at 100° C. (212° F.) until it ceases to lose weight, the residue, cooled in a desiccator, should weigh not less than 0.77 Gm. (corresponding to 7 molecules or 23 percent. of water of crystallization). If to 1 Cc. of an aqueous solution of Quinine Bisulphate (1 in 100) there be added 2 Cc. of bromine T.S., and then 1 Cc. of ammonia water, the liquid should acquire an emerald-green color (*thalleioquin*). Sulphuric acid should produce not more than a faintly yellow tint (limit of carbonizable organic impurities). Dissolve 2 Gm. of Quinine Bisulphate, which has been dried at 50° C. (122° F.) for two hours, in 20 Cc. of distilled water, carefully neutralize with diluted sodium hydroxide T.S., and evaporate the solution to dryness on a water-bath. Complete the test by following the directions given on page 1046 under *Quininæ Sulphas* (Test for Other Cinchona Alkaloids, Section II.)" U. S.

On account of its great solubility this salt is to be preferred to the neutral salts whenever rapid absorption is desired, and especially for hypodermic medication. Its dose is about 25 per cent. greater than that of the sulphate, on account of its greater proportion of acid.

Dose, two to ten grains (0.13 to 0.65 Gm.).

QUININÆ HYDROBROMIDUM. U. S.

QUININE HYDROBROMIDE [Quininæ Hydrobromas, Pharm. 1890, Quinine Hydrobromate]

(qui-ni'næ hÿ-dro-brō'mî-dŭm)

"The hydrobromide [$HBr.C_{20}H_{24}N_2O_2 + H_2O$] of the alkaloid quinine. It should be kept in well-stoppered, amber-colored vials." U. S.

Bromhydrate de Quinine Basique, *Fr. Cod.*; Monobromhydrate de Quinine, *Fr.*; Chininum Hydrobromicum; Chininhydrobromid, *Bromwasserstoffsaures Chinin*, *G.*

This official salt may be made by suspending 10 parts of quinine sulphate in 80 parts of water, boiling, and adding 3.4 parts of barium bromide dissolved in 20 parts of water, filtering, evaporating, and crystallizing. It may also be made by Leger's process, as follows: Quinine sulphate, commercial, crystallized, 40 parts; potassium bromide, dried and powdered, 11 parts; alcohol (80 per cent.), 400 parts; distilled water, 400 parts. Dissolve the sulphate in two hundred parts of alcohol by the aid of heat, add the potassium bromide, dissolved in thirty parts of distilled water, and continue the heat five or six minutes, in order to allow the potassium sul-

phate, which is formed, to acquire greater compactness, so that it will more readily settle. Filter off from the precipitate, and wash four times with fifty parts of boiling alcohol. Let the alcoholic solution cool, when a further small quantity of potassium sulphate will be deposited. The solution is then again filtered through white filtering paper, and evaporated on a water bath to one hundred parts. Next, four hundred parts of distilled water are poured on, and heat is applied until the hydrobromide is completely dissolved. After allowing the solution to stand in the cold for about twenty-four hours, the dish will be found filled with a compact crystalline mass. The crystals are transferred to a filter, allowed to drain, and dried by exposure to air. Heating would cause them to fuse. The product thus obtained amounts to about thirty parts of perfectly white quinine hydrobromide. By evaporating the mother water to one-third of its volume, about six parts more may be obtained. It is absolutely necessary, as has been already pointed out by Boille, to redissolve the hydrobromide in water as above stated, if the salt is to be obtained in white and bulky crystals. The above quantity of four hundred parts should not be diminished, for, if this were done, the salt would separate at first in the form of an oily liquid, and afterwards would form a crystalline crust. (*Répert. de Pharm.*, 1880, p. 390; *N. R.*, Jan. 1881.)

Properties.—It is in "white, light, silky, needles; odorless, and having a very bitter taste. The salt effloresces on exposure to the air. Soluble in 40 parts of water, 0.67 part of alcohol, 16 parts of ether, 8 parts of glycerin, and very soluble in chloroform at 25° C. (77° F.); soluble in 3 parts of water at 80° C. (176° F.). When heated to 100° C. (212° F.) the salt loses its water of crystallization. At 152° C. (305.6° F.) it begins to fuse, forming a syrupy liquid at 200° C. (392° F.). On ignition it is slowly consumed, leaving no residue. Its solutions are neutral, or slightly alkaline to litmus paper, and when acidulated with diluted sulphuric acid show a vivid blue fluorescence. Ammonia water added to an aqueous solution of the salt produces a white precipitate, which is soluble in a large excess of the reagent. On precipitating a saturated aqueous solution of the salt with sodium hydroxide T.S., filtering, supersaturating the filtrate with acetic acid, adding chloroform and a little chlorine water, and shaking, the chloroform will separate with a yellow color. If 1 Gm. of the salt be dried at 100° C. (212° F.) until it ceases to lose weight, the residue should weigh not less than 0.957 Gm. (corresponding to 1 molecule, or 4.25 percent. of water of crystallization). If to 1 Cc. of a solution of Quinine Hydrobromide (1 in 100) 2 Cc. of bromine T.S. be added, and then 1 Cc. of ammonia water, an emerald green color should be produced (*thalleioquin*). Quinine hydrobromide should not impart more than a faintly yellowish tint to concentrated sulphuric acid

(limit of readily carbonizable organic impurities), nor produce a red color with nitric acid (difference from *morphine*). Aqueous solutions of the salt should not be rendered more than faintly turbid by barium chloride T.S. (limit of *sulphate*). If to 5 Cc. of a saturated aqueous solution of potassium ferricyanide 25 Cc. of water, 15 drops of ferric chloride T.S., and 5 Cc. of diluted hydrochloric acid be added, a clear brown solution should result. On adding to this 0.1 Gm. of Quinine Hydrobromide, shaking well, and allowing it to stand for five minutes, no blue color should be developed (difference from *morphine*). Dissolve 3 Gm. of Quinine Hydrobromide, which has been dried at 50° C. (122° F.) for two hours, in 30 Cc. of hot distilled water in an evaporating dish, and add 1.5 Gm. of crystallized sodium sulphate gradually, with constant stirring, and evaporate the liquid on a water-bath to dryness. Complete the test by following the directions given on page 1046, under *Quininæ Sulphas* (Test for Other Cinchona Alkaloids, Section II.), using 30 Cc. of distilled water for maceration instead of 20 Cc. as there directed." *U. S.*

Uses.—This salt is well fitted for hypodermic injection, on account of its ready solubility, but is not superior, if equal, to the bisulphate. The plan which has been advocated of injecting a hot saturated solution is to be deprecated, as tending to cause precipitation in the cellular tissue. It is very capable of causing cinchonism, but the amount of hydrobromic acid is too small to sensibly affect the system.

Dose, from two to ten grains (0.13 to 0.65 Gm.).

QUININÆ HYDROCHLORIDUM.

U. S., Br.

QUININE HYDROCHLORIDE [Quininæ Hydrochloras, Pharm. 1890, Quinine Hydrochlorate]

(qui-nī'næ hÿ-dro-çhlô'rj-dûm)

"The hydrochloride [$\text{HCl} \cdot \text{C}_{20}\text{H}_{24}\text{N}_2\text{O}_2 + 2\text{H}_2\text{O}$] of the alkaloid quinine. It should be kept in well-stoppered, amber-colored vials." *U. S.* "The hydrochloride, $\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}_2 \cdot \text{HCl}$, $2\text{H}_2\text{O}$, of an alkaloid obtained from the bark of various species of Cinchona and Remijia." *Br.*

Muriate of Quinine; Chlorhydrate de Quinine Basique, *Fr. Cod.*; Chlorhydrate de Quinine, *Fr.*; Chininum hydrochloricum, *P. G.*; Chininhydrochlorid, *Salzsaures Chinin, G.*; Cloridrato di chinina, *It.*

This quinine salt was recommended for admission to the Br. Ph. 1885 by W. Martindale on account of its being more soluble in water and richer in quinine than is the sulphate. It may be readily prepared by treating the alkaloid with diluted hydrochloric acid, or by double decomposition between barium chloride and quinine sulphate. Quinine hydrochloride is in

"white, silky, glistening needles; odorless, and having a very bitter taste. The salt effloresces when exposed to warm air. Soluble in 18 parts of water, 0.6 part of alcohol, 240 parts of ether, 0.8 part of chloroform, and in 8 parts of glycerin at 25° C. (77° F.); soluble in 0.4 part of water at 80° C. (176° F.). When heated to 120° C. (248° F.), the salt loses its water of crystallization. At about 156° C. (312.8° F.), it begins to melt, but is not fully melted until the temperature reaches 190° C. (374° F.). On ignition it is slowly consumed, leaving no residue. Its aqueous solution is neutral or faintly alkaline to red litmus paper, and is not fluorescent except when greatly diluted, or when sulphuric acid is added to it.¹ Silver nitrate T.S. produces in aqueous solutions of the salt a white precipitate, insoluble in nitric acid. If 1 Gm. of the salt be dried at 100° C. (212° F.) until it ceases to lose weight, the residue should weigh 0.91 Gm. (corresponding to 2 molecules or 9.1 percent. of water of crystallization). If to 1 Cc. of a solution of Quinine Hydrochloride (1 in 100) 2 Cc. of bromine T.S. be added, and then 1 Cc. of ammonia water, an emerald-green color should be produced (*thalleioquin*). Sulphuric acid should produce no color (absence of readily carbonizable organic impurities). Aqueous solutions of the salt should not be rendered more than faintly turbid by barium chloride T.S. (limit of *sulphate*). If to 5 Cc. of a saturated solution of potassium ferricyanide 25 Cc. of water, 15 drops of ferric chloride T.S., and 5 Cc. of diluted hydrochloric acid be added, a clear brown solution should result. On adding to this 0.1 Gm. of Quinine Hydrochloride, shaking well, and allowing it to stand for five minutes, no blue color should be developed (difference from *morphine*). Dissolve 3 Gm. of Quinine Hydrochloride, which has been dried at 50° C. (122° F.) for two hours, in 30 Cc. of hot distilled water in an evaporating dish, and add 1.5 Gm. of crystallized sodium sulphate gradually, with constant stirring, and evaporate the liquid on a water-bath to dryness. Complete the test by following the directions given on page 1046, under *Quininæ Sulphas* (Test for Other Cinchona Alkaloids, Section II.), using 30 Cc. of distilled water for maceration instead of 20 Cc. as there directed." *U. S.*

"It is soluble in about 35 parts of cold water, in 3 parts of cold alcohol (90 per cent.), and very soluble in boiling water and alcohol (90 per cent.). It affords the reactions characteristic of hydrochlorides. It should yield only the slightest characteristic reactions with the tests for sulphates. When converted into quinine sulphate, by dissolving it together with an equal weight of sodium sulphate in ten times

¹In explanation of this it may be stated it is only the compounds of quinine with the oxygen acids that show the fluorescence in acid solution, none of the compounds of the haloid acids showing this reaction.

its weight of hot water, and setting the mixture aside at 60° F. (15.5° C.), it should respond to the characters and tests that are mentioned under 'Quininæ Sulphas.' Dried at a temperature of 212° F. (100° C.), it loses 9 per cent. of water." *Br.*

Quinine hydrochloride has a decided advantage over the sulphate in its greater solubility in water. It is, however, less soluble than the acid quinine hydrochloride (see below).

Dose, two to ten grains (0.13 to 0.65 Gm.).

QUININÆ HYDROCHLORIDUM ACIDUM. *Br.*

ACID QUININE HYDROCHLORIDE

(qui-ni'næ hÿ-drô-çhlô'rî-dûm âç'l-dûm)

"The acid hydrochloride, $\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}_2\text{HCl}$, $3\text{H}_2\text{O}$, of an alkaloid obtained from the bark of various species of Cinchona and Remijia." *Br.*

Chlorhydrate de Quinine Neutre, *Fr.*; Saures Chininhydrochlorid, *Saures Chlorwasserstoffsaures Chinin*, *G.*

This is an official quinine salt of the *Br. Pharm.* 1898. It has been introduced on account of its remarkable solubility in water,—*i.e.*, less than its own weight. It may be made by passing hydrochloric acid gas over dry quinine, but more conveniently by decomposing quinine bisulphate with barium chloride or by mixing a solution of neutral hydrochloride with one molecular proportion of hydrochloric acid and evaporating the solution at a gentle heat. It is officially described as "a white crystalline powder soluble in less than its own weight of water, yielding a somewhat acid liquid. It affords the reactions characteristic of hydrochlorides. It should yield only the slightest characteristic reactions with the tests for sulphates. Each gramme, when dissolved in 20 cubic centimetres of water, should require for its complete neutralization not more than 2.5 cubic centimetres of volumetric solution of soda. When converted into quinine sulphate, by dissolving it together with an equal weight of sodium sulphate in ten times its weight of hot water, exactly neutralizing this liquid with solution of ammonia, and setting it aside at 60° F. (15.5° C.) to cool, it should respond to the characters and tests which are mentioned under 'Quininæ Sulphas.' Dried at a temperature of 212° F. (100° C.), it loses not more than 12 per cent. of water." *Br.*

The solubility of this salt fits it for use in hypodermic and rectal injections. Its physiological and therapeutic action and its dose are those of quinine sulphate.

Dose, two to ten grains (0.13 to 0.65 Gm.).

QUININÆ SALICYLAS. U. S.

QUININE SALICYLATE

(qui-ni'næ sâl-i-cÿ'lâs)

"The salicylate [$2\text{C}_{20}\text{H}_{24}(\text{OH})\text{COOH}\cdot\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}_2 + \text{H}_2\text{O}$] of the alkaloid quinine. It should be kept in amber-colored, well-stoppered vials." *U. S.*

Salicylate de Quinine Basique, *Fr. Cod.*; Salicylate de Quinine, *Fr.*; Chininsalicylat, Salicylsaures Chinin, *G.*; Salicclato quínico, *Sp.*

Preparation.—Quinine salicylate may be made by adding a solution made by dissolving 3.9 parts of sodium salicylate in 30 parts of water, to a hot solution made by dissolving 10 parts of quinine sulphate in 75 parts of boiling water. The precipitate is collected, washed and dried and recrystallized from its solution in alcohol.

Properties.—It is officially described as in "colorless needles, permanent in the air, but on keeping readily assuming a pinkish color. Soluble in 77 parts of water, 11 parts of alcohol, 110 parts of ether, 37 parts of chloroform, and in 16 parts of glycerin at 25° C. (77° F.); soluble in 35 parts of water at 80° C. (176° F.), and in 11 parts of alcohol at 60° C. (140° F.). When heated, it begins to melt at 183° C. (361.4° F.), with decomposition, and at 187° C. (368.6° F.) is entirely melted to a red liquid. When ignited, it is slowly consumed, without leaving a residue. Its aqueous solution is alkaline to red litmus paper, and has a bitter taste. When treated with diluted sulphuric acid, its aqueous solution develops a blue fluorescence. Its aqueous solution, when treated with a drop of ferric chloride T.S., should give a violet color. Sulphuric acid containing about one-fifth of its volume of solution of formaldehyde gives a pink color. If to 10 Cc. of a dilute aqueous solution of Quinine Salicylate there be added 3 Cc. of bromine T.S. and then an excess of ammonia water, an emerald-green color should be produced (*thalleioquin*). When heated at 100° C. (212° F.), to constant weight, it should lose not more than 2 percent. in weight (absence of excessive moisture). Mix 2 Gm. of Quinine Salicylate with 10 Cc. of distilled water, in a separator, add a slight excess of ammonia water, and shake the liquid with three successive portions of 25, 20, and 10 Cc. of ether, collect the ether-solution in a porcelain dish and evaporate it to dryness on a water-bath, dissolve the residue in alcohol, add just sufficient sulphuric acid to render the liquid exactly neutral, and again evaporate to dryness. Complete the test by following the directions given on page 1046, under *Quininæ Sulphas* (Test for Other Cinchona Alkaloids, Section II.)." *U. S.*

Uses.—Quinine salicylate is believed by many practitioners to be a valuable remedy in the

advanced stages of an *acute rheumatism*, in subacute rheumatism, and in mild *gouty* conditions. When the general system is in a condition of lowered vitality ten to fifteen grains (0.65 to 1.0 Gm.) may be given daily.

Dose, from two to ten grains (0.13 to 0.65 Gm.).

QUININÆ SULPHAS. U. S., Br.

QUININE SULPHATE

(qui-ni'næ sŭl'phās)

"The sulphate [$\text{SO}_2(\text{OH})_2 \cdot (\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}_2)_2 + 7\text{H}_2\text{O}$] of the alkaloid quinine. It should be kept in well-stoppered bottles, preferably of an amber color, and in a dark place." *U. S.* "The sulphate, $[(\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}_2)_2 \cdot \text{H}_2\text{SO}_4]_{2.15}\text{H}_2\text{O}$, of an alkaloid obtained from the bark of various species of *Cinchona* and *Remijia*." *Br.*

Sulfas Quinicus; Disulphate or Basic Sulphate of Quinia; Sulfate de Quinine Basique, *Fr. Cod.*; Chininum Sulfuricum, *P. G.*; Chininsulfat, *Schwefelsaures Chinin, G.*; Solfato di chinina, *It.*; Sulfato quinico basico, *Sp.*

No process is given in the *U. S. Pharm.* for preparing quinine sulphate; that of the *U. S. P.* 1870 will be found in detail in the *U. S. D.*, 17th ed., p. 1141. The process, briefly stated, is to exhaust cinchona bark by boiling with water acidulated with hydrochloric acid and adding milk of lime in excess. The quinine is precipitated with lime, and the dried precipitate digested with boiling alcohol; the alcoholic solution of quinine is evaporated, and the mass dissolved in water acidulated with sulphuric acid. The hot solution is treated with animal charcoal to decolorize it, and then set aside to crystallize.

Pelletier proposed to substitute oil of turpentine for alcohol in the ordinary process for procuring quinine sulphate. The impure quinine, precipitated by lime from the acidulous decoctions, after being washed, pressed, and dried, is digested with the oil, which dissolves the quinine. The solution thus obtained is agitated with water acidulated with sulphuric acid, by which quinine sulphate is formed. The oil, separating, rises to the top, and is removed for future use, and the aqueous solution of the salt is evaporated, and treated as in the original process. A disadvantage of this method is said to be that the oil does not completely exhaust the precipitate. A similar process has been employed here and in England, either *fusel oil* or *benzene* being substituted for oil of turpentine. In this instance, however, the solvent is added to the impure quinine, without separation from the acidulated decoction from which it was precipitated by lime. The mixture being well agitated, the fusel oil or benzene dissolves the alkaloids, and, rising to the surface of the liquid, is drawn off by a siphon. The solution thus drawn off is treated as above

with water acidulated with sulphuric acid, and the process is completed in the same manner. (See *P. J.*, xiv. 29, 92, and 139.)

The importation of quinine sulphate and salts of quinine amounted in 1903 to 3,300,444 ounces, valued at \$744,774; in 1904 to 3,796,139 ounces, valued at \$826,791; in 1905 to 2,904,277 ounces, valued at \$638,755. For a "commercial history of quinine," with statistics, see *D. C.*, 1896, 32. Quinine sulphate made in Java is now found in commerce. (*A. J. P.*, 1898, 345.)

When barks containing the alkaloids *cinchonidine* and *quinidine* are used, as their sulphates are much more soluble than that of quinine, it follows that in the mother waters left after the crystallization of quinine sulphate there will be found a portion of cinchonidine or quinidine sulphate, or of both. In fact, there is generally, under these circumstances, more or less of the sulphates of the four alkaloids, quinine, cinchonine, quinidine, and cinchonidine, all of which are contained in many barks, and, besides these, a portion of amorphous alkaloid, incapable of crystallization, probably resulting, in part at least, from the heat employed in the process. These may in a great degree be separated through their different solubilities in water. Quinine sulphate, being least soluble, will first crystallize, afterwards the cinchonidine or quinidine salt, and finally that of cinchonine, which is the most soluble, while the uncrystallizable salt will remain in solution, and may be obtained in the amorphous state by evaporation to dryness.

Properties.—"White, silky, light, flexible, glistening crystals, or hard, prismatic, monoclinic needles, making a very light and easily compressible mass, odorless, and having a persistent, very bitter taste. It effloresces rapidly when it is exposed to dry air, and then becomes lustreless; when exposed to light it acquires a brownish tint. Quinine Sulphate sometimes crystallizes with 8 molecules of water of crystallization (16.18 percent.). Soluble in 720 parts of water, 86 parts of alcohol, 400 parts of chloroform, and in 36 parts of glycerin at 25° C. (77° F.); very difficultly soluble in ether; soluble in 45 parts of water at 80° C. (176° F.), and in 9 parts of alcohol at 60° C. (140° F.). Diluted acids increase its solubility in water, and it is easily soluble in a mixture of chloroform 2 parts, and absolute alcohol 1 part. Quinine Sulphate which has been dried over sulphuric acid melts at 205° C. (401° F.). When heated to 60° C. (140° F.), or when exposed to dry air, it loses all but 2 molecules of its water of crystallization, and upon heating it to 115° C. (239° F.), the remainder is expelled. Upon ignition, the salt is slowly consumed, without leaving a residue. Its aqueous solution is neutral to litmus paper, and when acidulated with diluted sulphuric acid, develops a vivid blue fluorescence. Barium chloride T.S. produces a white precipitate, insoluble in hydrochloric acid. On treating 10 Cc. of an

aqueous solution of the salt (about 1 in 1300) with 5 drops of bromine T.S., then with an excess of ammonia water, the liquid should acquire an emerald-green color (*thalleioquin*). With proper adjustment of the reagents, more diluted solutions will give a paler tint, while more concentrated ones will acquire a deeper color, or throw down a green precipitate." U. S. "Filiform silky white crystals, of an intensely bitter taste. Soluble in about 800 parts of water, giving a solution which has a bluish fluorescence. Entirely soluble in water acidulated with a mineral acid. Aqueous solutions of quinine salts yield with solution of ammonia white precipitates, soluble in ether and in excess of the solution of ammonia. When such aqueous solutions are treated first with solution of bromine or of chlorine and afterwards with solution of ammonia, they become of an emerald-green color, changing to red when mineral acids are added. Exposed to dry air, Quinine Sulphate effloresces until the 15 molecules of water have been reduced to 4. It affords the reactions characteristic of sulphates." Br. Its cold solution is opalescent.

The acid quinine salts possess fluorescent properties with the exception of those of the haloid acids. It has also been discovered that the presence of acetphenetidin conceals the fluorescence of sulphuric acid solutions of quinine. The diluted acids, and tartaric and oxalic acids in excess, dissolve the sulphate easily. With an additional equivalent of sulphuric acid it forms another sulphate, which is more soluble in water than the official salt, and crystallizes from its solution with much greater difficulty. This is now considered by many as strictly neutral, and therefore entitled to the name of quinine sulphate, while the official salt contains two equivalents of base to one of acid, and is therefore a quinine subsulphate or di-quinine sulphate. The latter name was adopted by the London College, and has been much used by chemical writers. In the U. S., Dublin, and Edinburgh Pharmacopœias, as well as in the French Codex, the name of quinine sulphate, originally given to the official salt, under the impression that it was neutral, was retained; and it has been assumed by the 1898 British Pharmacopœia. Hence has arisen a confusion of nomenclature, which must embarrass the student. The following statement may serve to clear up this confusion. There are at least three quinine sulphates that have been obtained, of which two are now official. The first of these,

is a "diquinine sulphate," but is the official salt known as quinine sulphate, or Quininæ Sulphas, U. S.; the second, formed by dissolving this first in dilute sulphuric acid, has the formula

and is the official quinine bisulphate, or Quininæ Bisulphas, U. S.; while the third, a still more acid sulphate,

may be obtained from a solution of quinine in

excess of diluted sulphuric acid. This salt is not official. Quinine sulphate, owing to the ease with which it parts with its water of crystallization, is apt to mislead those who seek to determine its quality. Forty samples examined by A. J. Cowley showed results varying from 8.1 to 15.95 per cent. of water of crystallization. He recommends for adoption in the Pharmacopœia the air-dried salt, which contains two molecules of water (4.6 per cent.), as being constant in composition. Farr and Wright confirm Cowley's views, and object to "anhydrous" quinine sulphate, which has been proposed by some chemists as the standard, because it has the opposite fault of absorbing moisture. (P. J., 1896, 525; also P. J., 1897, 203.)

Incompatibles and Tests.—"One Gm. of the salt should dissolve completely when heated to 50° C. (122° F.) in 7 Cc. of a mixture of 2 volumes of chloroform and 1 volume of absolute alcohol, and the solution should remain clear on cooling (absence of ammonium sulphate and inorganic salts). Sulphuric acid should impart to the salt not more than a faintly yellowish tint (limit of readily carbonizable organic impurities). Nitric acid should not produce a red color (difference from morphine). If 1 Gm. of the salt be dried at a temperature of 115° C. (239° F.), until it ceases to lose weight, the residue should weigh not less than 0.833 Gm. (indicating not more than 8 molecules or 16.18 percent. of water)." U. S. "2.5 grammes of the freshly prepared salt should lose 0.33 gramme of water by drying at 212° F. (100° C.). Heated to redness with free access of air, it burns without leaving any residue (absence of mineral impurity)." Br. The official test (see page 1046) is probably the most reliable of all to prove the presence of small quantities of other cinchona alkaloids. It is a modification of Kerner's,¹ and admits the presence of

¹ Kerner's test (G. Kerner, *Zeitschrift für Analytische Chemie*, 1862) distinguishes the alkaloids by their solubilities in ammonia water of given strength, which, according to Kerner, are more fixed and reliable than their solubilities in water or other ordinary solvent. The mode of application is by taking a certain quantity of the sulphate of the alkaloid dissolved in a certain quantity of water, and then adding the ammonia water gradually until the precipitated alkaloid is redissolved: the quantity of the ammoniacal liquid necessary to produce this effect indicates inversely the solubility of the alkaloid. Quinidine requires from 10 to 11 times more of the ammoniacal liquid than quinine, cinchonidine from 12 to 13 times more, while cinchonine is not dissolved by a much larger proportion than is required by either of the others, and though when mixed in very small proportion with quinine it is dissolved at first, yet it afterwards separates on standing. This test is now official, and as modified is regarded as the best test for quinine sulphate. Kerner's test has been elaborately criticised and discussed; it appears that in order to get results which are at all trustworthy it is necessary to be exceedingly careful to observe the specific gravities and temperatures ordered by the test. (See Parson's paper, *Proc. A. Ph. A.*, 1884; *Am. Drug.*, 1885, also 1888; *D. C.*, 1888; *P. J.*, 1887; *Ph. Era*, 1887, also 1888.) In De Vrij's *Chromate Test for Quinine* 5 Gm. of quinine sulphate are dissolved in 500 Gm. of water at the boiling temperature, and 1.20 Gm. of potassium chromate dissolved in a little hot water are added. The precipitate at first produced is rapidly redissolved.

a trace of other alkaloids. This certainly is as pure as the quinine sulphate need be. To separate the remaining trace of alkaloids entirely would more than double the cost of the salt.

"*Test for Other Cinchona Alkaloids.*—I. Dry 2 Gm. of Quinine Sulphate in a porcelain dish on a water-bath for two hours at 50° C. (122° F.). II. Transfer the residue (which should be strictly neutral to litmus paper) to a dry test-tube, add 20 Cc. of distilled water and place the test-tube in a water-bath; heat it for half an hour at 65° C. (149° F.) and then allow to cool, and keep the temperature at 15° C. (59° F.) for two hours, shaking the test-tube occasionally. Filter the liquid, transfer 5 Cc. of the filtrate, having the temperature of 15° C. (59° F.), to a dry test-tube, and carefully add ammonia water (which must be of official strength and have the temperature of exactly 15° C.) until the precipitate which forms has just redissolved; not more than 6 Cc. of ammonia water should be required to produce a clear solution. If the temperature at the end of the digestion has risen to 16° C. (60.8° F.), not more than 6.5 Cc. of ammonia water should be required; if to 17° C. (62.6° F.), not more than 7 Cc. of ammonia water should be used. (In each case a clear solution indicates the absence of excessive amounts of other cinchona alkaloids.)" *U. S.* For Hera-path's test (*quinine iodo-sulphate*), see *U. S. D.*, 17th ed., p. 1144. The British Pharmacopœia gives the following tests for the presence of other cinchona alkaloids:

"Quinine Sulphate when tested by the following methods should not afford any appreciable reaction characteristic of cinchonine, quinidine, cupreine, or amorphous alkaloid, and should not yield more than a total of 3 per cent. of crystals of impure cinchonidine by the following test.

Test for Cinchonidine and Cinchonine.—Dissolve 4 grammes of the Quinine Sulphate in 120 cubic centimetres of boiling water. Cool the solution slowly to 122° F. (50° C.), with frequent stirring. Separate, by filtration, the purified quinine sulphate which has crystallized out. Concentrate the filtrate by evaporation until it is reduced to 10 cubic centimetres or less; transfer to a small stoppered flask, and,

solved, and in from 5 to 10 seconds crystallization begins, star-shaped groups of sulphur-yellow needles of anhydrous quinine chromate— $2(C_{20}H_{24}N_2O_4) \cdot H_2CrO_4$ —being formed. The separation of these crystals is practically complete when the liquid has cooled, but it is advisable not to collect the crystals before the day following their formation. They are washed with a small quantity of water, dried, and weighed; 766.5 parts of quinine chromate are equal to 648 parts of quinine or to 890 parts of quinine sulphate. The mother liquors contain the cinchonidine, together with a small quantity of quinine chromate amounting to 0.05 Gm. in 100 Gm., and to this extent the yield of quinine chromate, by weighing, must be corrected. To ascertain the amount of cinchonidine present the total filtrate and washings are rendered alkaline by soda solution and evaporated to 300 Gm. The cinchonidine separates during the heating, and, after cooling, is collected on a filter, dried at 100° C., and weighed. (*A. Pharm.*, 1886, p. 1022.)

when cold, shake with 10 cubic centimetres of ether and half that amount of solution of ammonia. Set aside in a cool place for not less than 24 hours. Collect the crystals, which consist of cinchonidine and cinchonine combined with quinine, on a tared filter, wash with a little ether, dry at 212° F. (100° C.), and weigh. These should not amount to more than 0.12 gramme.

Test for Quinidine.—Dissolve 1 gramme of the Quinine Sulphate in 30 cubic centimetres of boiling water; cool, and filter. To the solution add solution of potassium iodide and a little alcohol (90 per cent.) to prevent the precipitation of amorphous hydriodides. Collect any separated quinidine hydriodide, wash with a little water, dry, and weigh. The weight represents about an equal weight of crystallized quinidine sulphate. None or only the slightest traces should be obtained.

Test for Cupreine.—Shake the recrystallized quinine sulphate, obtained in testing the original Quinine Sulphate for cinchonidine and cinchonine, with 25 cubic centimetres of ether and 6 cubic centimetres of solution of ammonia, and to this ethereal solution, separated, add the ethereal liquid and washings also obtained in testing the original sulphate for the two alkaloids just mentioned. Shake this ethereal liquid with 6 cubic centimetres of a 10 per cent. solution of sodium hydroxide, adding water if any solid matter should separate. Remove the ethereal solution. Wash the aqueous solution with more ether, and remove the ethereal washings. Add diluted sulphuric acid to the aqueous liquid heated to boiling, until exactly neutral. When cold, collect any crystallized sulphate of cupreine on a tared filter; dry, and weigh. None or only the slightest traces should be obtained.

Test for Cinchonine and Amorphous Alkaloids.—Dissolve 1 gramme of the Quinine Sulphate in 30 cubic centimetres of boiling water, add 1 gramme of sodium potassium tartrate. Allow to cool, with frequent stirring; filter. The solution when evaporated to small bulk should give little or no precipitate with solution of ammonia." *Br.*

Quinine sulphate is decomposed by the alkalis, their carbonates, and the alkaline earths. In solution it affords white precipitates with potassium and sodium hydroxides, and ammonia, which are partly soluble in an excess of alkali. It is also precipitated by astringent infusions, the tannic acid of which forms a white insoluble compound with quinine. The soluble salts of lead and of barium occasion precipitates; and that produced by the salts of barium is insoluble in the acids. The soluble salts of acetic, oxalic, tartaric, and gallic acids occasion more or less precipitation with solution of quinine sulphate without excess of acid. A solution of chlorine added to a solution of quinine sulphate and followed by the addition of ammonia water occasions an emerald-green color, and, in certain proportions, the deposition of a green

precipitate. The green compound has received the name of *thalleioquin*. The drop of ammonia should be put in without agitation. According to Flückiger, 1-5000th part of quinine can thus be found. With bromine instead of chlorine the test is more delicate. Flückiger states that 1-20,000th part of the alkaloid can be detected. (See a paper by C. F. Zeller, *A. J. P.*, 1880, p. 385; *P. J.* 1872, p. 901.) F. S. Hyde (*Proc. A. Ph. A.*, 1897, 704) states that a solution of calcium hypochlorite gives more satisfactory results in the thalleioquin test than either chlorine or bromine water, the results being more certain and brilliant. If, previously to the use of ammonia in the chlorine test, a concentrated solution of potassium ferrocyanide be added, a dark red color is produced, which persists for several hours, but ultimately passes into green. This does not take place with cinchonine; and, though quinidine sulphate gives the same red color, this does not disappear as with the quinine salt, but is persistent. (Schwartz, *J. P. C.*, 4e sér., iii. 475.) Quinine sulphate gives a reddish-brown precipitate with iodine dissolved in a solution of potassium iodide. It is possible that under some circumstances the galvanic current may be of service in detecting the alkaloid; a paper on the electrolysis of the salt will be found in the *J. P. C.*, 4e sér., xi. 16.¹ For valuable comments on quinine sulphate tests, see *Proc. A. Ph. A.*, 1897, 705.

Adulterations.—Quinine sulphate has often been adulterated. The effects of adulteration may be produced by the variable quantity of water which quinine sulphate may contain, without any observable alteration in its sensible properties. Millon and Commaille, having exposed quinine sulphate to a very moist atmosphere at the temperature of about 16.6° C. (62° F.), found it always to increase in weight, so that a specimen of the salt, previously deprived of all its water capable of being separated by heat, had in five days absorbed 28.77 per cent. of water, and another specimen dried after its precipitation simply by draining, and supposed to contain 18 per cent. of water, had in ten days absorbed 14 per cent. more, making its whole percentage of water 32, or about one-third of its weight. (*J. P. C.*, Nov. 1862, p. 379.) This is an important fact, and will explain to some extent the frequent variable effects from apparently the same quantity of the salt. It is easy to detect and to obviate this natural sophistication by exposing a suspected specimen to a heat of 115° C. (239° F.). The loss of weight will indicate the quantity

of water not essential to the salt. Calcium sulphate,² and other alkaline or earthy salts, gum, sugar, mannite, starch, stearin, caffeine, salicin, phlorizin, and the cinchonine sulphate, and sulphates of other cinchona alkaloids, are among the substances which are said to have been fraudulently added. By attending to the degree of solubility of the sulphate in different menstrua, and to its chemical relations with other substances already described, there can be little difficulty in detecting these adulterations. The presence of any mineral substances not readily volatilized may be at once ascertained by exposing the salt to a red heat, which will completely dissipate the quinine sulphate, leaving the mineral behind. A volatile ammonium salt may be detected by the odor of ammonia emitted upon the addition of potassium hydroxide. The absence of organic substances may be inferred if pure cold concentrated sulphuric acid forms a colorless solution. Gum and starch are left behind by alcohol, and fatty matters by water acidulated with sulphuric acid. Sugar and mannite cause a solution of the salt in acidulated water to have a sweet taste after the precipitation of the quinine by an alkaline carbonate. Salicin imparts the property of becoming red upon the contact of sulphuric acid; but, according to Pelletier, this change of color does not take place unless the proportion of salicin exceeds one-tenth. If only in this proportion, the salicin must be isolated. To 1 part of the suspected salt, 6 parts of concentrated sulphuric acid may be added, and to the brown liquid which results, 125 parts of water. The salicin is thus separated, and may be obtained by filtration, in the form of a bitter, white powder, becoming bright red with sulphuric acid. (See *A. J. P.*, xvii. 156.) Caffeine alters the solubility of the medicine in different menstrua. According to Calvert, a saturated solution of quinine sulphate in cold water gives with a solution of chlorinated lime a precipitate soluble in an excess of the latter, while a solution of cinchonine sulphate of the same strength, treated in the same manner, gives a precipitate which is insoluble in a great excess of the reagent. The same effect is produced with lime water, and with solution of ammonia, and solution of calcium chloride, while it furnishes a precipitate with a solution of cinchonine sulphate, yields none with a solution of quinine sulphate. (*J. P. C.*, 3e sér., ii. 394.) Though commercial quinine sulphate frequently contains a portion of one or more of the other cinchona alkaloids, the salt is only slightly less efficacious on that account, as these alkaloids have been shown to possess identical therapeutic properties with those of quinine, and to be little inferior in strength to them.

¹ Morphine has been mixed with quinine with fatal results. If there be more morphine than will form 1-1000th part of the solution, the thalleioquin test will fail to develop the green color. The morphine in these cases is to be recognized by adding nitric acid or ferric chloride to the suspected powder, or, better still, iodic acid, which is decomposed by the alkaloid and forms a beautiful violet solution with chloroform. This test is said to succeed with solutions containing less than 1-10000th part of morphine. (*P. J.*, May, 1872, 901.)

² *Flora China*.—According to W. A. Puckner (*West. Drug.*, 1896, 393), nearly pure crystallized calcium sulphate in fine needle-shaped crystals has been exploited as quinine sulphate under the name of *flora china*.

Uses.—The first symptoms of cinchonism, as produced by small therapeutic doses of quinine (ten grains) in man, are usually ringing in the ears, slight fullness in the head, and perhaps some deafness. With the use of larger doses these symptoms are intensified; the deafness is very marked, disturbed vision may exist, and the flushed face, with the sense of distention in the head, may point towards a cerebral congestion, which is in some cases relieved by spontaneous epistaxis. In decided cinchonism, giddiness and staggering in walking are very common. After toxic doses, severe headache, delirium, stupor, complete deafness and blindness, dilated pupils, embarrassment of respiration, great weakness, convulsions, paralysis, and finally collapse, either comatose or delirious, may result. The deafness produced by large doses of quinine usually passes off rapidly; very rarely is there a permanent impairment of hearing. Amaurosis, with a peculiar ischæmia of the retinal vessels, has in a small number of cases been produced by very large therapeutic doses of the alkaloid. Besides its effects on the brain, quinine sulphate sometimes occasions great gastric and intestinal irritation, marked by oppression of stomach, nausea, abdominal pains, vomiting, and purging. In general, these effects of excessive doses gradually pass off, although partial deafness often continues for several days, and sometimes much longer, and permanent deafness has resulted. It is capable of taking life, although enormous amounts of it are requisite for this. Several cases of recovery are recorded after the taking of an ounce by the stomach. Probably only a portion of the drug was absorbed. Five ounces taken in ten days have caused death.

Although it is not possible at present to explain, with complete satisfaction, all the clinical uses of quinine from its known physiological action, yet it seems proper to speak here briefly of our knowledge of its influence upon the healthy organism, referring the reader for details to H. C. Wood's *Treatise on Therapeutics*. The action of the drug upon the cerebrum is somewhat uncertain. It is probable that moderate doses stimulate the brain to some extent, especially the basal ganglia connected with the special senses, and it is very certain that toxic doses overwhelm and paralyze the gray matter of the brain. Upon the spinal cord of man therapeutic doses produce no marked effect. Two facts, first pointed out by T. A. Chaperon (*Pflüger's Archiv*, 1869, p. 295), have been so abundantly substantiated that we must accept them as established. They are—quinine in small doses causes in the frog a lessening of the reflex activity, which is removed by section of the medulla; quinine in large doses produces a permanent palsy of reflex activity. The first of these actions is considered to show that the alkaloid stimulates Setschenow's centre in the base of the brain, the second is probably due to a paralysis of the spinal cord. It has

been proved by Binz and subsequent observers that when the alkaloid is added to blood outside of the body in a proportion of not less than one part to four thousand it immediately checks, and finally arrests, the amoeboid movements of the white blood corpuscles. How far this occurs when the medicine has been taken into the living organism has not been exactly determined, but we certainly are not able to appreciate any such effect in health or disease by therapeutic doses. The ozonizing power of the red corpuscles in drawn blood is lowered by the addition of quinine. Ordinary therapeutic doses exert, however, no perceptible influence. How far the marked antipyretic influence exerted by large doses of quinine is dependent upon its action upon the blood is at present purely a matter of conjecture. In 1765, Pringle called attention to the power of cinchona bark over putrefaction, and it has recently been experimentally proved by Binz, Hallier, Pavesi, and others, that one part of the alkaloid in three hundred parts of milk, albuminous solutions, meat, honey, syrup, etc., will keep in check for a long time putrefaction and other fermentations. Binz has shown that this is due to a poisonous influence upon the low forms of life which accompany or produce these changes. Introduced into the jugular vein or coronary artery, or in any way brought in direct contact with the heart, it lessens the force and frequency of the pulsations, and finally produces diastolic arrest. In man, very large doses of quinine (thirty to sixty grains) lower the force and frequency of the pulse; a pulse rate of forty has been noted, and in reported cases of quinine poisoning the pulse has been imperceptible at the wrist. Under the latter circumstances the pulse rate may be increased, but the cardiac force is reduced to a minimum. The evidence is conclusive that both in man and in the lower animals quinine in sufficient amount is a powerful depressant to the heart muscle or ganglia. An enormous amount has been written during the last ten years concerning the action of quinine upon the uterus. The result of it all seems to indicate positively that the alkaloid has no power to originate uterine contractions in the pregnant female, but that when once parturition has commenced the flagging pains are greatly stimulated and increased by a dose of ten grains of the drug. When abortion is threatened through malarial influence no hesitation need be felt in using the drug to avert the impending catastrophe. Any salt of quinine which escapes absorption in the stomach must be precipitated by the alkaline juices of the bowels, and be absorbed very slowly or not at all. What seems *a priori* almost inevitable has been shown to be the case by the researches of Kerner, who found the alkaloid in the fæces. The importance of giving the salt in some easily soluble form, if it is intended for all of it to be absorbed, is plain. When taken into the system, it seems to find its way into all the

secretions,—it having been found in the tears, sweat, milk, urine, and saliva. Some of it is eliminated unchanged, but, according to the researches of G. Kerner, a portion of it escapes in an amorphous uncrystallizable form and a second portion as a substance free from bitter taste, though crystallizable and having the fluorescence of quinine; for this substance he has proposed the name of *dihydroxyl-quinine*. Upon the elimination both of uric acid and of urea the salts of quinine appear to have a decided influence, decreasing it very noticeably.

Quinine sulphate may be given in pills, capsules or solution, or suspended in water by the intervention of syrup and mucilage. The form of pill is usually preferred. The solution may be readily effected by the addition of a little acid of almost any kind to the water. Eight grains (0.5 Gm.) of the sulphate will dissolve in a fluidounce (30 Cc.) of water acidulated with about twelve minims (0.7 Cc.) of the diluted sulphuric acid or aromatic sulphuric acid of the Pharmacopœias. One of the best ways of exhibiting it to children is to mix the dose quickly with half a teaspoonful of aromatic elixir or syrup of licorice and administer it before it can dissolve. A few drops of laudanum may be added if nausea or disturbance of the bowels is apprehended. J. S. Blockley ascertained that glycerin will, if gently heated, dissolve eight grains of the sulphate in each fluidrachm, and may therefore be conveniently used as a vehicle. (*Lond. Chemist*, Sept. 1857.) R. H. Thomas of Baltimore, found that one part of tannic acid will deprive five parts of quinine sulphate of bitterness, without impairing its efficacy. (*Am. J. M. S.*, N. S., xix. 541.) It is obvious that quinine tannate is thus formed, and as this, though insoluble in water, is readily dissolved in diluted acids, and consequently in the gastric liquor when acid, there can be no doubt that it will generally prove efficacious. It may, however, happen that the stomach may be quite free from acid, and that the operation of this salt may prove less certain than that of the sulphate, and such is asserted to have been the case in some instances, but a little lemonade taken after the medicine would probably obviate the difficulty.

Quinine is used in practical medicine as a tonic, antiperiodic, antipyretic, and a uterine stimulant. It is certainly the most efficient remedy known in *malarial diseases*, in which it acts by poisoning the *Plasmodium malarie* first detected in the blood of persons suffering from malarial disease by Laveran, and now generally recognized as the infectious cause of the disease. It should be administered in such a way that the last dose shall be ingested about two hours before the expected return of the paroxysm, and the first dose four or five hours previous to the last. When there is sufficient time, its influence is almost always very sensibly aided by the exhibition, twelve or more hours before, of a mercurial or other purge. Quinine exerts in *febrile disease* a decided antipyretic

action, which is especially manifested during those stages of disease in which the natural tendency is towards a lowering of temperature. In *typhus* and *typhoid fever*, *scarlatina*, *severe erysipelas*, *rheumatic hyperæmia*, etc., after the use of the cold bath, twenty grains of the alkaloid are often very efficacious in preventing a rapid return of the excessive fever.

Twelve grains of quinine sulphate are equivalent to about an ounce of good bark. The dose varies exceedingly, according to the circumstances of the patient and the object to be accomplished. As a tonic simply, a grain (0.065 Gm.) may be given three or four times a day, or more frequently in acute cases. In *intermittents*, from twelve to twenty-four grains (0.78 to 1.6 Gm.) should be given between the paroxysms, divided into smaller or larger doses according to the condition of the stomach or the length of the intermission. From one to four grains (0.065 to 0.26 Gm.) may be given at once, and some even advise the whole amount. In *malignant intermittents* and *remittents*, the quantity may be increased to thirty grains (2.0 Gm.) or even ninety grains (5.8 Gm.) between the paroxysms. When the stomach will not retain the medicine, it may be administered with nearly as much efficacy by enema,—from six to twelve grains (0.4 to 0.78 Gm.) with two fluidounces (60 Cc.) of acidulated starch water, and from twenty to forty drops (1 to 2 Cc.) of laudanum, being injected into the rectum, in ordinary cases, every six hours. Should circumstances render this mode of application impracticable, the hypodermic syringe should be resorted to. If the ordinary sulphate be used, the solution for hypodermic use should be made with tartaric acid, grain for grain, and should always be carefully filtered. The sulphovinate has been especially recommended, but is of doubtful advantage. (*P. J.*, May, 1875, p. 909.) The official hydrobromide and bisulphate have been considered the best forms for hypodermic use, but it is affirmed that *Laveran's solution* (hydrochloride of quinine, 3, antipyrine, 2, distilled water, 6) affords a 50 per cent. quinine solution, of which the injection is painless.¹ Administered hypodermically, quinine acts with great promptness; but no precaution will always prevent the production of severe local abscesses and ulcerations by the hypodermic use of quinine, and even fatal tetanus has been induced, so that the method should be employed only in emergencies.

Locally applied to the mucous membrane, quinine is stimulant or irritant, according to its concentration. In meningitis, gastritis, enteritis, cystitis, or in inflammation of the middle ear, its evil effects may be very pronounced. In *whooping cough* the use of quinine by atomization has been warmly recommended. In *hay fever* a warm solution, as nearly neutral as

¹ Santesson and Sjoquist believe that a new salt is formed, to which they have given the name of *Chinopyrin*. The antimalarial powers of the solution are well attested.

possible, and of the strength of two grains to the fluidounce (0.13 Gm. to 30 Cc.), may be used with the Thudichum douche.

Dose, one to ten grains (0.065 to 0.65 Gm.).

RESINA. U. S., *Br.*

ROSIN [Resin, Colophony]

(re-şī'nā)

"The residue left after distilling off the volatile oil from turpentine." *U. S.* "The residue left after the distillation of the oil of turpentine from the crude oleo-resin (turpentine) of various species of *Pinus*." *Br.*

Colophone ou Arcanson, *Fr. Cod.*; Résine blanche, Résine jaune, *Fr.*; Colophonium, *P. G.*; Kolophonium, Geigenharz, Fichtenharz, *G.*; Colofonia, Pece greca, *It.*; Colofonia, Pez griega, *Sp.*

After the distillation of the volatile oil from the turpentine (see *Terebinthina*), a resinous matter remains, which on the continent of Europe is called *colophony*, but with us is commonly and now officially known by the name of *rosin*. It is the *Resina* of the U. S. and British Pharmacopœias. It is sometimes called *resina flava*, or *yellow rosin*. When this, in a state of fusion, is strongly agitated with water it acquires a distinct appearance, and is denominated *resina alba*, or *white rosin*. The ports from which rosin is shipped are Wilmington, N. C., Charleston, S. C., and Savannah, Ga. The exports of rosin in 1904 amounted to 2,585,108 bbls., valued at \$6,621,870; and in 1905 to 2,310,275 bbls., valued at \$7,069,084.

Common or *yellow rosin*, in its purest state, is beautifully clear and pellucid, but much less so as usually found in commerce. Its color is yellowish brown with a tinge of olive, and more or less dark, according to its purity and the degree of heat to which it has been exposed in its preparation. Sometimes it is almost black. It is rather heavier than water. It is completely liquid at 152.5° C. (306° F.), begins to emit bubbles of gas at 157.5° C. (316° F.), and is decomposed at a red heat. "Usually in sharp, angular fragments, translucent, amber-colored, usually covered with a yellowish dust; at ordinary temperatures brittle, pulverizable; fracture shiny and shallow-conchoidal; odor and taste faintly terebinthinate. The specific gravity of Rosin is 1.070 to 1.080; it is easily fusible, and burns with a dense yellowish smoke, yielding no appreciable ash; soluble in alcohol, ether, benzene, carbon disulphide, acetic acid, fixed or volatile oils, and in solutions of potassium or sodium hydroxide; acid number not less than 150. (See PART III, Test No. 98.)" *U. S.* "Translucent, of a light amber color, compact, brittle, pulverizable; fracture shining; odor and

taste faintly terebinthinate. It is soluble in alcohol (90 per cent.), ether, benzol, and carbon disulphide, is easily fusible, and burns with a dense yellow flame and much smoke, leaving no appreciable ash." *Br.* The composition of rosin is expressed by the formula $C_{44}H_{82}O_4$, which is the formula ascribed to *abietic anhydride*. Jean, however (*Chem. News*, xxvi. 207), has separated two other resinoid substances in addition to abietic acid. Lewkowitsch (*Chem. Analysis of Oils*, etc., 2d ed., 236) states that rosin also contains varying quantities of unsaponifiable matter,—viz., hydrocarbons due to the partial breaking up of the acid on distilling the pine rosin. This may vary from 5 to 9 per cent. in the American rosin. For a paper on abietic acid by Mead and Kremers, see *Proc. A. Ph. A.*, 1893, 198. By shaking coarsely powdered rosin with dilute alcohol and warming, it is converted into *abietic acid*, $C_{44}H_{82}O_6$, obviously an hydroxide of the first. Rosin may be considered, therefore, as abietic acid anhydride, $C_{44}H_{82}O_4$. Rosin, when it is boiled with alkaline solutions, forms greasy salts of abietic acid, the so-called rosin soaps which are used in admixture with other soaps. As the acid is dibasic, these salts contain two atoms of alkali metal in combination. Rosin, distilled by itself, yields the so-called "rosin oil," of which two fractions are taken separately,—the first that distilling under 360° C. (674° F.), and the second that over 360° C. (674° F.),—and some 31 per cent. of fixed gases.¹ When distilled with superheated steam, rosin yields benzene and toluene. *Sylvic acid*, formerly considered to be a constituent of rosin, is now regarded as a decomposition product of abietic acid. Similarly *pinic* and *pimaric acids*, announced as found in rosin, are impure products, although the latter acid, or one of the same name, is found in galipot resin. Propionic acid has, according to Renard, been obtained in abundance from the tar produced by the destructive distillation of rosin. (*A. Pharm.*, 1886, p. 939.)

A. Tschirch and B. Studer determined the nature of the constituents of American rosin. According to Mohr, the principal plant yielding the turpentine from which the American rosin is obtained is *Pinus palustris*, Mill.; to some extent also, *P. heterophylla*, Ell.; rarely *P. echinata*, *P. Taeda* and *P. scoprida*. The sample under examination (presumably from *P. palustris*) was completely soluble in the ordinary solvents for resin, including petroleum benzin, in which some other varieties of rosin are only

¹The lighter fraction is known commercially as *rosin essence*, and is, according to Renard (*J. Chem. S.*, Aug. 1884, p. 843), composed of hydrocarbons, representing almost all series, from the paraffin series to the terpenes, including pentane and hexane, amylene and hexylene, toluene, xylene, and cumene, the tetra- and hexahydrides of all three of these, terebenthene and cymene. Several aldehydes and acids of the fatty series, such as isobutyric and valeric, were also recognized. The heavier fraction, or rosin oil in the stricter sense of the word, is composed of polymers of the hydrocarbons C_nH_{2n-2} , which readily resinify by the absorption of oxygen. This accounts for the use of rosin oil as an adulterant of linseed oil in the manufacture of printers' ink.

partly soluble. Its alcoholic solution is strongly acid in reaction. Its sp. gr. at 15° C. was 1.090. Its composition was proved to be as follows:

1. Acids soluble in ammonium carbonate: *α*-abietinic acid, $C_{19}H_{35}O_2$, forming an insoluble lead salt, 30 per cent. *β*-abietinic acid, $C_{19}H_{35}O_2$, not forming a lead salt, 22 per cent. 2. Acid soluble in sodium carbonate: *γ*-abietinic acid, $C_{19}H_{35}O_2$, insoluble in ammonium carbonate, 31.06 per cent. 3. Volatile oil, 0.4 to 0.7 per cent. 4. Resen, 5 to 6 per cent.

The impurities amounted only to 0.1 per cent., the loss in operation, however, to 10 per cent. Fabrian having proposed a method for the differentiation of different rosins, based upon their relative solubility in petroleum benzin, the authors determined the amount of solvent necessary to dissolve 1 Gm. of rosin, freshly powdered, and old powder; also abietinic acids and the resen in petroleum benzin, with the following results:

Rosin, old powder, 1 Gm. required....	400 Cc.
Rosin, fresh, 1 Gm. required.....	60 Cc.
<i>α</i> -Abietinic acid, 1 Gm. required.....	500 Cc.
<i>β</i> -Abietinic acid, 1 Gm. required....	100 Cc.
<i>γ</i> -Abietinic acid, 1 Gm. required....	100 Cc.
Resen	50 Cc.

These results show that all the resin-acids, as well as the rosin, are more or less soluble in petroleum benzin, and that fresh rosin is more readily soluble than the isolated acids, a peculiarity which has also been noticed in the case of other bodies. On the other hand, old rosin is much less soluble in petroleum benzin than is fresh rosin. (*A. Pharm.*, Oct. 1903, 495-522.)

White rosin differs from the preceding only in being opaque and of a whitish color. These properties it owes to the water with which it is incorporated, and which gradually escapes upon exposure, leaving it more or less transparent. A new and very interesting class of derivatives from colophony or rosin has been prepared by Eugen Schaal of Feuerbach, Germany, and introduced into commerce under the name of *ester gums*. These are the *glyceryl, methyl, and ethyl esters of abietic acid*, made by heating the resin acid and the alcohol under pressure until saponification takes place. The product is then distilled off under reduced pressure. These "*ester gums*" are now being used to advantage as substitutes for copal, damar, and kauri gums in varnish making.

Uses.—Rosin is important as an ingredient of ointments and plasters, but is rarely used internally. It has been given in *chronic enteritis*, five grains of the powder. According to Olmsted, it has the property of preventing the oxidation of fatty substances, and thus contributes to the preservation of ointments. (*A. J. P.*, xxii. 325.)

RESINA JALAPÆ. U. S. (Br.)

RESIN OF JALAP

(re-ŝī'na ja-lă'pæ)

Jalapæ Resina, Br.; *Résine de Jalap, Fr. Cod.*; *Jalapenharz, G.*; *Resina di gialappa, It.*; *Resina de jalapa, Sp.*

* "Jalap, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*. Moisten the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until *twenty-five hundred cubic centimeters* [or 84 fluidounces, 256 minims] of percolate are obtained, or until the percolate ceases to produce more than a slight turbidity when dropped into water. Distil off the Alcohol, by means of a water-bath, until the percolate is reduced in weight to *two hundred and fifty grammes* [or 8 ounces av., 358 grains], and add the latter slowly, with constant stirring, to *three thousand cubic centimeters* [or 101 fluidounces, 212 minims] of water. When the precipitate has subsided, decant the supernatant liquid, and wash the precipitate twice, by decantation, with fresh portions of hot water. After having drained off all the liquid, transfer the Resin to a porcelain dish and heat it to dryness on a water-bath." *U. S.*

"Jalap, in No. 40 powder, 8 ounces (Imperial) or 100 grammes; Alcohol (90 per cent.), *a sufficient quantity*; Distilled Water, *a sufficient quantity*. Digest the Jalap with twice its weight of the Alcohol in a covered vessel, heating gently, for twenty-four hours; transfer to a percolator; when the tincture ceases to pass, continue the percolation with successive portions of the Alcohol until nothing more is dissolved; add to the tincture thus produced *four fluid ounces* (Imp. meas.) or *fifty cubic centimetres* of the Distilled Water; remove the alcohol by distillation; transfer the residue while hot to an open dish; allow it to become cold; pour off the supernatant fluid from the resin; wash this two or three times with hot Distilled Water; dry." *Br.*

The two processes probably do not differ very materially in the result, though, if jalap yields anything to alcohol that is insoluble in water besides resin, it will be necessarily found in the British preparation, while that of the U. S. Pharmacopœia will consist of resin almost exclusively. The difference arises from

the circumstance that in the Br. process, probably to enable the whole of the alcohol to be saved by distillation, the water for precipitation is added before the spirit is distilled off, while in the U. S. process it is not added until so much of the alcohol has been distilled as to leave only enough to hold the extracted matters in solution. It is obvious, therefore, that the resin of the former contains everything insoluble in water that the alcohol had extracted, while that of the latter contains nothing which water was unable to precipitate from the strong tincture left in the still.

Properties.—Resin of jalap is officially described in the U. S. Pharmacopeia as in "yellow to brown masses or fragments, breaking with a resinous, glossy fracture, translucent at the edges, or a yellowish-gray to yellowish-brown powder, having a slight, peculiar odor, and a somewhat acrid taste. Permanent in the air. Soluble in alcohol in all proportions; insoluble in carbon disulphide, benzene, and fixed or volatile oils. Its alcoholic solution has a faintly acid reaction to blue litmus paper. Not more than 10 percent. of Resin of Jalap should be soluble in ether, and not more than 35 percent. in chloroform. Slowly but completely soluble in 5 times its weight of ammonia water; when this solution is acidified with hydrochloric acid, only a slight turbidity should appear (absence of *rosin*, *guaiac*, and *other resins*). Resin of Jalap should not suffer any material loss of weight when heated at 100° C. (212° F.) (absence of *water*). Anhydrous Resin of Jalap melts at about 150° C. (302° F.). Water triturated with Resin of Jalap should neither become colored nor dissolve any portion of it (absence of *soluble impurities*). No greenish-blue color should be produced on adding a few drops of ferric chloride T.S. to some of the powder moistened with alcohol (absence of *guaiac*). One Gm. of Resin of Jalap when dissolved in 50 Cc. of alcohol containing 1 Cc. of phenolphthalein T.S. should require not more than 0.5 Cc. of half-normal alcoholic potassium hydroxide V.S. to produce a red color (limit of *acid resins*). If to 1 Gm. of Resin of Jalap, dissolved in 50 Cc. of alcohol in a flask, 25 Cc. of half-normal alcoholic potassium hydroxide V.S. be added, and the mixture be heated on a water-bath for one hour, and if the excess of alkali be titrated with half-normal sulphuric acid V.S., using 5 drops of phenolphthalein T.S., as indicator, at least 20 Cc. of half-normal sulphuric acid V.S. should be required (limit of *saponifiable substances*)."
U. S. "In dark-brown opaque fragments, translucent at the edges, brittle, breaking with a resinous fracture, readily reduced to a pale-brown powder, sweetish in odor, acrid to the throat, easily soluble in *alcohol* (90 per cent.), insoluble in *oil of turpentine*. The powder yields little or nothing to warm *water*, and not more than 10 per cent. to *ether* (indicating absence of scammony resin and resin of Tampico jalap). A

solution in *alcohol* (90 per cent.) is not colored bluish-green by *test-solution of ferric chloride* (absence of *guaiacum resin*)."
Br.

The U. S. resin, although pure enough for practical purposes, is still colored. To obtain it colorless, the powdered jalap should be mixed, before percolation, with an equal quantity of finely powdered animal charcoal, and, previously to the introduction of this mixture into the percolator, half the quantity of animal charcoal, similarly powdered, should be packed in the bottom of the percolator. The coloring matter is thus left behind, and the resulting tincture, treated as directed in the process, yields the resin as white as starch. Resin of jalap consists of two portions, one of which is hard and insoluble in ether, the other is soft and soluble in that menstruum, the former constituting about 90 per cent. It is insoluble in oil of turpentine. (*Squire*.) For its chemical properties, see *Jalapa*. It was at one time supposed that the purgative properties resided chiefly, if not exclusively, in the hard resin, but experiments by John C. Long appear to prove that the soft resin is equally energetic. (*A. J. P.*, 1861, p. 489.)

Guaiac, rosin, and other resinous substances are said to be sometimes fraudulently added to the resin of jalap. Guaiac may be detected by the green color it produces when a few drops of solution of sodium or calcium chloride are added to an alcoholic solution of the suspected resin. (*J. P. C.*, 3e sér., x. 357.) When pure jalap resin is dissolved in an alkaline solution, it is not precipitated by the addition of sulphuric or hydrochloric acid, having been converted, through the agency of the alkali, into an acid soluble in water. All the adulterating resins yield precipitates under the same circumstances. The resins of scammony and of fusiform jalap act in this respect like the true jalap resin, but are distinguishable by being wholly soluble in ether, while jalap resin is not. (*N. R. Pharm.*, No. 1, 1854.)

It is now generally believed that the resin of jalap is the sole purgative principle of jalap, the gummy extractive being either simply diuretic or wholly inert. To obviate the occasional harshness of the resin, it has been advised to triturate it with milk sugar, potassium sulphate, almond emulsion, or other substance calculated to separate its particles. It may be conveniently made into pills with mucilage or alcohol. (*Hasselby*, *P. J.*, 2d ser., vii. 231.)

Dose, two to five grains (0.13 to 0.33 Gm.).

RESINA PODOPHYLLI. U. S. (Br.)

RESIN OF PODOPHYLLUM [Podophyllin]

(re-sí'na pód-o-phýl'lí)

Podophylli Resina, *Br.*; Resin of May-Apple; Résine de Podophyllum Peltatum, *Fr. Cod.*; Podophyllinum, *P. G.*; Podophyllin, Podophyllumharz, *G.*; Podofillina, *It.*; Podofillino, *Sp.*

* "Podophyllum, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Hydrochloric Acid, *ten cubic centimeters* [or 162 minims]; Alcohol, Water, each, a *sufficient quantity*. Moisten the powder with *four hundred and eighty cubic centimeters* [or 16 fluid-ounces, 111 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until *sixteen hundred cubic centimeters* [or 54 fluidounces, 48 minims] of percolate are obtained, or until the percolate ceases to produce more than a slight turbidity when dropped into water. Distil off the Alcohol, by means of a water-bath, until the percolate is reduced to the consistence of a thin syrup, and pour it slowly, with constant stirring, into *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of water, previously cooled to a temperature below 10° C. (50° F.), and mixed with the Hydrochloric Acid. When the precipitate has subsided, decant the supernatant liquid, and wash the precipitate twice, by decantation, with fresh portions of cold Water. Spread it in a thin layer, upon a strainer, and dry the Resin by exposure to the air, in a cool place, protected from the light. Should it coalesce during the drying, or aggregate into lumps having a varnish-like surface, it should be removed, broken in pieces, and rubbed in a mortar. It should be kept in amber-colored, well-stoppered vials." *U. S.*

"Podophyllum Rhizome, in No. 40 powder, 1 *pound* (Imperial) or 400 grammes; Alcohol (90 per cent.), 3 *pints* (Imp. meas.) or 1500 cubic centimetres or a sufficient quantity; Distilled Water, Hydrochloric Acid, of each a *sufficient quantity*. Exhaust the Podophyllum with the Alcohol by percolation; place the resulting tincture in a still; recover the greater part of the alcohol; acidulate the Distilled Water with one twenty-fourth of its bulk of Hydrochloric Acid, and slowly pour the liquid which remains after the distillation of the tincture into three times its volume of the acidulated water, constantly stirring; allow the mixture to stand for twenty-four hours to deposit the resin; wash the resin on a filter with Distilled Water, and dry it at a temperature not exceeding 100° F. (37.7° C.)." *Br.*

The British Pharmacopœia (1885) abandoned the use of hydrochloric acid, as it is not necessary if the tincture is evaporated to the consistence of *thick honey*. Hydrochloric acid was directed in the 1898 revision as it seems to aid the precipitation when the tincture is not so concentrated. The color and yield of resin of podophyllum may be made to vary by adding *alum*, acids, or other substances to the water. It darkens if dried with the aid of heat, and

its color is indeed no indication whatever of its quality. The average yield of resin is about 5 per cent.

Resin of podophyllum has usually a light-brown color, an acrid bitter taste, and a slight odor of the rhizome. It consists of two resins, one soluble both in ether and alcohol, the other in alcohol only. The resin extracted by ether constitutes, according to John W. Cadbury, 75 per cent. of the whole (*A. J. P.*, July, 1858, p. 301), according to Harvey Allen, 80 per cent. (*Ibid.*, May, 1859, p. 206.)

Properties.—It is officially described as "an amorphous powder, varying in color from grayish-white to pale greenish-yellow, turning darker when subjected to a heat exceeding 35° C. (95° F.) or when exposed to light. It has a slight, peculiar odor and a faintly bitter taste; very irritating to the mucous membrane, especially to that of the eyes. Soluble in alcohol in all proportions; not less than 75 percent. of Resin of Podophyllum should be soluble in ether, not less than 65 percent. in chloroform, and not more than 25 percent. in boiling water. A hot, aqueous solution deposits most of its contents on cooling, and if the cooled liquid be filtered, the filtrate has a bitter taste, and turns brown upon the addition of a few drops of ferric chloride T.S. Soluble in potassium or sodium hydroxide T.S., forming a deep yellow liquid, which gradually becomes darker on standing, and from which the Resin is reprecipitated by acids. Not less than 99 percent. of Resin of Podophyllum should be soluble in alcohol; the solution should be clear or, at most, slightly opalescent, and should have a faintly acid reaction. Upon incineration, Resin of Podophyllum should yield not more than 0.7 percent. of ash." *U. S.* "An amorphous powder, of a bitter taste, varying in color from pale yellow to deep orange-brown; soluble or nearly so in alcohol (90 per cent.) and in *solution of ammonia*; precipitated from the former solution by water, from the latter by acids. Partly soluble in ether. It should not yield more than 1 per cent. of ash upon incineration." *Br.* G. M. Beringer (*A. J. P.*, 1894, 11) obtained different results in the U. S. 1890 solubilities by testing a fresh sample. The official resin is soluble in alkaline solutions, from which it is precipitated by acids, in this respect differing strikingly from the resins of jalap and scammony. It is insoluble in oil of turpentine. The name *podophyllin*, given to it by the eclectic practitioners, who have long been in the habit of using this resin, is inappropriate, and should be abandoned.

Lohmann (*Proc. N. J. Pharm. Assoc.*, 1896, 51) states that the fresh drug does not yield as large a percentage of resin as the same drug would if tested after being stored for several years; his experiments led him to the conclusion that in the order of value of resin of podophyllum obtained by various methods, that made by precipitation with water alone came first, that made by the U. S. P. process second,

and that made by precipitation with solution of alum last, the doses being in the following order: first, one-hundredth grain; second, one-fourth to one-half grain; third, one to one and a half grains. Dohme and Kelly (*D. C.*, 1903, 251), replying to statements in a paper by Lohmann (*Proc. A. Ph. A.*, 1903, 317) regarding the yield of resin from podophyllum, state that: 1, the yield from the method of pouring an alcoholic extract into water was 5 per cent.; 2, from pouring an alcoholic extract into acidulated water 5.5 per cent., and 3, from pouring an alcoholic extract into acidulated water containing 5 per cent. of alum, 4.9 per cent. See also *Podophyllum*, page 978. The color by process 1, is grayish-white; 2, light brown; 3, greenish-yellow. The value of resin of podophyllum is accurately estimated by the percentage of podophyllotoxin that it yields. Nearly all of the resin of podophyllum in commerce is made by the alum process, has a deep yellow color and is not wholly soluble in alcohol.

Uses.—Resin of podophyllum is a powerful cathartic, occasionally producing some griping and nausea, but capable of being favorably modified by combination, and of being very usefully employed in connection with other cathartics, to give them increased energy. It is supposed to be especially cholagogue, and this belief has been confirmed by the experiments of Rutherford. There has been much difference of opinion as to the relative activity of the two resins composing it, some maintaining that both are active, others that the activity resides mainly, if not exclusively, in the resin soluble in ether. It is difficult to resist the evidence of the experiments of Cadbury, who states in the paper above referred to that, while half a grain of the ethereal resin acted energetically, and a cathartic effect was produced by even one-fourth of a grain, the portion insoluble in that menstruum was given in the dose of one grain without any effect whatever. Moreover, this evidence was subsequently confirmed by the experiments of F. B. Power. (*A. J. P.*, xlv. 227.) It is asserted by Power, and confirmed by Maisch (*Ibid.*, 226), that the purgative principle of podophyllum is soluble in hot water.¹ The researches of Power (*A. J. P.*, 50, p. 369), Maisch (*P. J.*, 1880, p. 621), Quereschi (*Ber. d. Chem. Ges.*, 12, p. 683), and Podwysotszki have established the fact that podophyllum does not contain berberine or any alkaloid, and that its activity is due to principles in the resins. (See *Podophyllum*.) Resin of podophyllum is a mixture of the active and inert principles of the rhizome. A small proportion of extract of belladonna or hyoscyamus mitigates its irritant action. Care

must be taken in handling it in quantity, as it is a powerful irritant, frequently producing conjunctivitis.

Dose, one-eighth to one-fourth of a grain (0.008 to 0.016 Gm.).

RESINA SCAMMONII. U. S. (Br.)

RESIN OF SCAMMONY

(re-sī'nə scam-mō'nī-i)

Scammonia Resina, *Br.*; Résine de Scammonée, *Fr. Od.*; Scammoniaharz, *G.*; Resina di scammonia, *It.*

* "Scammony, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, Water, each, a sufficient quantity. Digest the Scammony with successive portions of boiling Alcohol until it is exhausted. Mix the liquids, filter, and reduce the mixture to a syrupy consistence by distilling off the Alcohol. Then add the residue in a thin stream, with active stirring, to twenty-five hundred cubic centimeters [or 84 fluidounces, 256 minims] of Water, separate the precipitate formed, wash it thoroughly with Water, and dry it at a gentle heat." *U. S.*

"Scammony Root, in coarse powder, 8 ounces (Imperial) or 150 grammes; Alcohol (90 per cent.), a sufficient quantity; Distilled Water, a sufficient quantity. Exhaust the Scammony Root with the Alcohol by percolation; place the resulting tincture in a still; recover the greater part of the alcohol; slowly pour the liquid which remains after the distillation of the tincture into three times its volume of the Distilled Water, constantly stirring; allow the mixture to stand for the resin to subside; then wash the resin on a filter with boiling Distilled Water and dry it on a water-bath." *Br.*

The U. S. and British resins, though the former is procured from the gum-resin and the latter from the root of the plant, are nearly identical in their effects. Indeed, the elaborate researches of H. Spirgatis (*A. J. P.*, xlv. 421) appear to have established the identity of the two products. A. Hess, however (*Ibid.*, 1875, p. 210), states that the resin obtained from the root contains tannic acid. The advantage of the preparation is that the resin is obtained free from the inert matters with which it is often associated in the scammony of commerce. When pure virgin scammony can be procured, any preparation is unnecessary. Obtained according to the U. S. process, the resin is of a dirty greenish-brown color, with a feeble odor and taste of scammony, and is very soluble in ether, alcohol, and boiling proof spirit. When purified with animal charcoal it has a pale brownish-yellow color, and is without odor or taste, and retains its purgative property. "Yellowish-brown or brownish-yellow masses or fragments, breaking with a glossy resinous fracture at the edges; or a yellowish-white or

¹ Under the name of *Podophyllin purissimum* the German chemists have put upon the market that portion of the resin of podophyllum which is soluble in ether. It should be of a pure yellow color, and should not be precipitated from its 50 per cent. alcoholic solution by the addition of 10 parts of ether.

grayish-white powder, having a faint, characteristic odor, and a slight, peculiar taste. Soluble in alcohol in all proportions, completely soluble in oil of turpentine, and almost completely soluble in ether and chloroform. Ammonia water and solutions of alkalis dissolve it with the aid of a gentle heat, and from these solutions the Resin is not reprecipitated by acids. When incinerated, it should not yield more than 1 percent. of ash. Sulphuric acid, when stirred in a porcelain dish with an equal weight of Resin of Scammony, should not gradually turn red (absence of *rosin*)." *U. S.* "Its solution in alcohol does not give a blue color with test-solution of ferric chloride, or with solution of hydrogen peroxide (absence of guaiacum resin). Ether dissolves it almost entirely (distinction from jalap resin)." *Br.* The *Br.* resin is in brownish translucent pieces, with a resinous fracture, and a sweetish fragrant odor derived from the root, and wholly different from that of scammony. Its tincture does not render the freshly-cut surface of a potato blue.

The resin of scammony is liable to adulteration. Jalap resin may be detected by its partial insolubility in rectified ether, which dissolves that of scammony in all proportions. Sulphuric acid is the best test of common rosin or colophony, producing instantaneously with this substance an intense red color, while with the resin of scammony it causes no immediate change. For the tests of guaiac, the reader is referred to that article on p. 603. (See also *A. J. P.*, xxiv. 158.) The presence of other resins may be known by the precipitates yielded when sulphuric acid is added to the alkaline solution, the resin of scammony agreeing with that of jalap in not affording a precipitate under such circumstances. Chas. Bullock has found the resins of scammony, of jalap, and of podophyllum to be insoluble in benzene, thus enabling any resin soluble in this liquid, which may be employed in the sophistication, to be readily detected. (*A. J. P.*, 1862, 114.) When rubbed with unskimmed milk, the resin of scammony forms a uniform emulsion, undistinguishable from rich milk itself. This is an excellent mode of administration. The resin should always be given either rubbed up with some mild powder or in emulsion.

Dose, four to eight grains (0.26 to 0.5 Gm.).

RESINÆ.

RESINS

(*re-sī'næ*)

The official *Resins*, with a single exception, constitute a peculiar class of preparations, made by exhausting the substances from which they are obtained by alcohol, and then precipi-

tating the resinous matter from the tincture by the addition of water, which abstracts the alcohol by its stronger affinity. It is obvious that the resins thus prepared are different substances from the alcoholic extracts, which contain all the ingredients of the medicine which alcohol is able to take from it. This set of substances has been much employed by the practitioners styling themselves "eclectics," but with great want of discrimination. They have applied names to these resinous precipitates which, in their proper scientific use, are employed to designate neutral proximate principles of plants, generally representing more or less completely the effects of the plants respectively on the system; as we say *columbin*, *quassin*, *santonin*, etc., themselves proper proximate principles, and representing the virtues, in part at least, of calumba, quassia, santonica, etc., from which they are obtained, and from which they derive their names. By applying similar names to their precipitated resins, such as podophyllin, iridin, cimicifugin, etc., *i.e.*, to the impure resins obtained by precipitating the tinctures of podophyllum, iris versicolor, cimicifuga, etc., they justify the suspicion either that they ignorantly believe them to be in fact the active principles of these medicines respectively, or that, knowing better themselves, they seek to impose such a conviction upon the ignorant. The fact is that the substances thus obtained, and thus named, are impure resins, which may possibly contain more or less of the active principles mixed with them, but are not entitled to names which imply that they are distinct proximate principles themselves.

Resins are solid, brittle, of a smooth and shining fracture, or in powder and generally of a yellowish-brown color. When perfectly pure, they are probably inodorous and often insipid; but, as usually found, they have a slight odor, and a somewhat acrid or bitterish taste. Their sp. gr. varies from 0.92 to 1.2. They are fusible by a moderate heat, decomposed at a higher temperature, and in the open air take fire, burning with a yellow flame and much smoke. Insoluble in water, they are mostly soluble in ether and the volatile oils, and in alcohol; and their alcoholic and ethereal solutions afford precipitates upon the addition of water. With pure potassium and sodium hydroxides they unite to form soaps, which are soluble in water, and the same result takes place when they are heated with solutions of the alkaline carbonates. Concentrated sulphuric acid dissolves them with mutual decomposition, and nitric acid converts them into artificial tannin. They readily unite by fusion with wax and the fixed oils.¹

¹ Losch recommends the following process for rendering the resins as white as possible. Boil together 5 parts of the resin, 1 of carbonate of potassium or of sodium, and 20 of water, until a perfectly homogeneous mass is obtained; allow this to cool, and pass into it sulphurous acid, which saturates the alkali, and precipitates the resin in white flakes. Finally, wash the precipitate well with water, and dry it. (*J. P. C.*, Jun, 1856, p. 465.)

RESORCINOL. U. S.

RESORCINOL [Resorcinum, Pharm. 1890, Resorcin]

(rē-sōr-sī'nōl)

 $C_6H_6O_2 = 109.22$

"A diatomic phenol [metadihydroxybenzene, $C_6H_4(OH)_2$ 1:3] obtained usually by the reaction of fused sodium hydroxide upon sodium metabenzenedisulphonate. Resorcinol should be kept in dark amber-colored vials." U. S.

Metadihydroxybenzene, Metadihydroxybenzene; Résorcine, *Fr. Cod.*; Resorcinum, *P. G.*; Resorcin, *G.*; Resorcina, *It. Sp.*

Resorcinol is *metadihydroxybenzene*, while pyrocatechin is the *ortho* compound and hydroquinone the *para* compound. Hlasiwetz and Barth first obtained this organic body in 1864 by fusing galbanum resin with potassium hydroxide; it was subsequently obtained from *sagapenum*, *asafetida*, *ammoniac*, and *gum acroides*. According to Kopp, it is prepared by the destructive distillation of *brazilin*, or from the wash or mother waters obtained in its manufacture from Brazil-wood. It is now generally prepared by fusing sodium benzene-disulphonate with sodium hydroxide.

Properties.—Resorcinol is a diatomic phenol, isomeric with *pyrocatechin* and *hydroquinone*. It crystallizes in prismatic crystals of the rhombic system, distilling at 276.5°C . (529.7°F .), easily soluble in water, alcohol, and ether, insoluble in chloroform and carbon disulphide. A small quantity treated with fuming sulphuric acid is dissolved, with the production of, first, an orange-yellow, then a greenish-blue, and finally a pure blue color. Bromine water precipitates its aqueous solution, *tribromoresorcin* separating in minute crystals. Several of the compounds of resorcinol with phthalic anhydride have assumed great technical importance as dye-colors under the names of *fluorescein*, *eosin*, and *uranine*. Its trinitro derivative is *styphnic acid*, $C_6H_3(OH)_2(NO_2)_3$, which is also formed from many of the gum-resins by the action of nitric acid.¹ It is officially described as in "colorless, needle-shaped crystals, having a faint, peculiar odor and a sweetish, followed by a bitter taste. It acquires a pinkish tint on exposure to light and air. Soluble in 0.5 part of water at 25°C . (77°F .), slightly more soluble in alcohol; very soluble in boiling water or in boiling alcohol; also readily soluble in ether and glycerin; very slightly soluble in chloroform, carbon disulphide, and benzene. When heated to 110° to 111°C . (230° to 231.8°F .) it melts and at a higher temperature is completely volatilized. It boils at 276.5°C . (529.7°F .) and is slightly volatile in a current of steam. Its aqueous solution is neutral or

only slightly acid to litmus paper. On adding a few drops of ferric chloride T.S. to 10 Cc. of an aqueous solution of Resorcinol (1 in 200), the liquid assumes a bluish-violet color, changing to brownish-yellow on the addition of ammonia water (distinction from *catechol* and *quinol*). Lead acetate T.S. should produce no precipitate when added to an aqueous solution of Resorcinol (distinction from, and absence of, *catechol*). If 0.1 Gm. of Resorcinol be dissolved in 1 Cc. of potassium hydroxide T.S. and a drop of chloroform added, the mixture upon being heated will assume an intense crimson color. If a slight excess of hydrochloric acid be then added, the color will change to a pale straw-yellow. On cautiously heating 0.05 Gm. of Resorcinol with 0.1 Gm. of tartaric acid and 10 drops of concentrated sulphuric acid, a thick carmine-red liquid will be formed, becoming pale yellow when diluted with water. A concentrated aqueous solution of Resorcinol (1 in 2) should be colorless (absence of *emphyreumatic bodies*), and when gently heated should not emit the odor of *phenol*." U. S.

Uses.—Resorcinol appears in its physiological properties to be allied to phenol. It is distinctly poisonous to the lower organisms, and, according to Martin Cohn (*In. Dis.*, Berlin, 1882) and Andeer (*Ueber das Resorcin*, Würzburg, 1880; also *Cb. M. W.*, 1881), a one per cent. solution of it is sufficient to arrest for a long time putrefactive changes in the urine, organic infusions, and even animal tissues. Platt, however, states (*Am. J. M. S.*, vol. i., 1883) that it is distinctly inferior to phenol as an antiseptic. When given to the lower animals (Dujardin-Beaumetz, *B. G. T.*, ci. 113) it causes tremors, loss of consciousness, and epileptiform convulsions, which, when the dose has been sufficiently large, become more and more violent and associated with marked disturbances of respiration; this function is finally arrested and death ensues. During the spasms the temperature of the animal is distinctly elevated, but when there is quiet narcosis it may fall much below the normal. The urine becomes olive green deepening into blackish. So far as we know, no case of fatal poisoning in man has been recorded. The largest therapeutic doses produce flushing of the face, with giddiness and buzzing in the ears and some quickening of the breathing and pulse, followed after a time by violent perspiration. Sixty grains caused in man giddiness, violent perspiration with marked anxiety, ending in collapse and unconsciousness. Andeer took about one hundred and fifty grains of resorcinol dissolved in a pint of water during fifteen minutes. After disturbance of cerebration and of the special senses, he fell into a condition of collapse, with cold extremities, epileptiform convulsions, opisthotonos, loss of consciousness, and marked irregularity of the respiration. Consciousness did not return for five hours. Murrell records (*M. T. G.*, vol. ii., 1881) a case in which a woman took one hundred

¹ Resorcinol combines with various principles. In this way arise *eucalyptoresorcinol*, *caffioresorcinol*, etc. (see *P. J.*, xxi. 977); also a brown powder said to be composed of resorcinol and iodoform which has been commended by Eidlafew (*S. M.*, 1892) as a stimulant application to foul ulcers, in *eczema*, etc. It is very irritant, and usually requires dilution (from 6 to 25 per cent.).

and twenty grains of resorcinol and immediately felt giddy, had sensation of pins and needles all over her, and a few minutes later became insensible, with closed eyes, clenched hands, groaning, with blanched lips, dry tongue, normal pupils, insensible conjunctiva, and a temperature of 94° F.; the patellar reflex was entirely gone; the pulse weak and thready.

The chief action of resorcinol is upon the nerve centres, although, like phenol, it probably affects all highly organized tissues. Beyer (*Am. J. M. S.*, April, 1886) stated that it has a direct paralytic action upon the heart.

As an antipyretic, resorcinol has been used by Lichtheim (*Correspondenzbl. f. Schweizer Aerzte*, July, 1880), Murrell, and other clinicians. It is, however, so much more dangerous and less effective than other members of the class that it is used exclusively as a topical remedy in diseases of the skin and of the mucous membrane. Internally it is of value in subacute and chronic gastric and intestinal catarrh, also in gastric ulcer and enteritis; externally in a solution of from one to fifteen per cent. it has been employed in hay fever, nasal catarrh, chronic otitis, gonorrhoea and leucorrhoea. The three to five per cent. solution has been largely used in washing out diseased stomachs but some care is necessary to avoid poisoning. In chronic cystitis irrigation with the three per cent. solution is often advantageous. In chronic and subacute eczema, where there is much thickening from exudation, resorcinol is a very valuable remedy, and it is also used in seborrhoea, psoriasis and pityriasis, and in the various parasitic skin diseases but in conditions of acute inflammations of the skin may increase the symptoms through its irritant action. According to Andeer, in powder it is a feeble caustic, which may be suitable for the treatment of chancres, papilloma, epithelioma, etc. As a local application to the skin it is preferably used in solution, from ten to thirty grains in one drachm of alcohol, one drachm of glycerin, and eight drachms of water, well sopped on the part and allowed to dry. Murrell affirms that he has given forty grains of resorcinol every four hours without the production of unpleasant symptoms, but this failure to do harm was probably because an impure article was exhibited. In gastric conditions it should be administered in solution, when the stomach is empty.

Dose, two to five grains (0.13 to 0.32 Gm.).

RHAMNUS PURSHIANA. U. S. (Br.)

CASCARA SAGRADA

(rhām'nūs pūr-shī-ā'na)

"The dried bark of *Rhamnus Purshiana* De Candolle (Fam. *Rhamnaceæ*), collected at least one year before being used." U. S. "The dried bark of *Rhamnus purshianus*, DC." Br.

Cascara Sagrada, Br., Fr. Coû.; Sacred Bark; Chittum Wood Bark; Cascara Sagrada, Sp.

A number of species of *Rhamnus* have been described as growing in California, but according to the best authority there are only four species,—*R. alnifolia*, L'Her., *R. crocea*, Nutt., *R. Purshiana*, DC., and *R. californica*, Esch. Of these species, *R. alnifolia* is too rare in the Cascara district to be important; while the spinous twigs, the very thick oval or roundish leaves, and the small roundish red fruit of *R. crocea* make it so distinct that it cannot be confounded with the Cascara, whose bark, moreover, its bark does not resemble. On the other hand, *R. californica* appears to be very commonly confounded with the official species by collectors, and to have yielded much of the cascara sagrada bark of commerce. *R. californica* is rare in Northern California, but abundant in the countries lying south and southeasterly, while *R. Purshiana* is abundant in Northern California, but scarce in the south, so that any bark collected in Northern California is probably genuine. *R. californica* is chiefly distinguished from the official species by its leaves being thin, and when not smooth having a short close pubescence, and the primary veins of the under surface not nearly so numerous, straight, or fine as those of *R. Purshiana*. Rusby thinks that its leaves are especially distinguished by the channel of the midrib of *R. californica* being altogether absent, or shallow, or inconspicuous. Nevertheless the species so run into one another that competent botanists believe them identical.

The *Rhamnus Purshiana* is a small tree, attaining a height of twenty feet. Its leaves are rather thin, elliptic, for the most part briefly acutely pointed, finely serrated, at the base obtuse, somewhat pubescent beneath, from two to seven inches long and from one to three wide. The rather large flowers are in somewhat umbellate cymes; the sepals five; the minute cucullate petals bifid at the apex. The fruit is black, broadly obovoid, four lines long, three-lobed, and three-seeded. The seeds are convex on the back, with a lateral raphe. It is found in California, extending northward to the British territories.

The *Rhamnus californica*, or *Californian buckthorn* or *California coffee-tree*, yields a bark which is of a dark brown color externally and bright yellow internally, having an intensely bitter taste, with a persistent nauseous after-taste, and very little odor. It is said to be much more distinctly purgative than that of *R. crocea*.

It does not seem possible to distinguish with certainty between the barks of the two species by their macroscopic appearance. The bark of *R. Purshiana* is usually more red than is that of *R. californica*, but it may be of a distinctly gray color. The microscopic structure of the two barks is, however, different. The medullary rays in *R. Purshiana* are numerous, thin, for a long distance nearly parallel and straight (according to L. E. Sayre, they converge at their outer ends), run nearly three-quarters of the distance through the bark, and

are commonly composed of two rows of cells. In *R. californica* the medullary rays are much broader, much shorter, and are composed usually of three or more rows of cells; further, they are crooked and not parallel throughout their course. Again, the zone of resin spaces is much broader in *R. californica*, and the spaces themselves much larger and more numerous, than in the official species. For further details and elaborations, see paper by H. H. Rusby, *Proc. A. Ph. A.*, 1890. According to L. E. Sayre (*A. J. P.*, March, 1897), the powder of the barks can be distinguished by paying attention to the fact that *R. Frangula* contains no stone cells, while in *R. californica* and *R. Purshiana* such cells are abundant, occurring in large, irregular groups below the cork and usually outside the region of the bast: *R. Purshiana* may also be distinguished from *R. californica* by color tests. After several days' maceration in dilute alcohol the powder of *R. Purshiana* appears of an orange-yellow color, *R. californica* of a purplish color; or if 0.2 Gm. of the powdered bark be placed in a small test tube, and there be added 2 Cc. of potassium hydroxide test-solution, *R. californica* will give a blood-red and *R. Purshiana* an orange-red color.

The bark of the *Rhamnus crocea*, the so-called *California mountain holly*, occurs in slightly curved pieces, externally of a dark brown color, internally of a characteristic red delicately streaked with numerous white veins. The odor is somewhat aromatic, the taste warming and not unpleasantly bitter. It is affirmed to be a tonic and mild laxative.

Properties.—Cascara sagrada occurs in commerce in the form of small broken pieces, often more or less flattened out into a somewhat compressed mass, and also as separated quills of varying length and size. The bark is "in quills or curved pieces, of variable length and 1 to 5 Mm. thick; outer surface reddish-brown, frequently more or less covered with grayish or whitish lichens, several of which are peculiar to this bark, and with small groups of their brownish fruit-heads; inner surface yellowish to light brownish, becoming dark brown with age and reddened by alkalies, longitudinally striate; fracture short, with projections of bast fibres in the inner bark, and the medullary rays forming converging groups; odor distinct; taste bitter and slightly acid."¹

¹The following elaborate microscopic description of cascara sagrada is abbreviated from that of J. Moeller (*A. J. P.*, Sept. 1882, 462.) The corky layer is about 0.045 Mm. thick, and consists of 8 or 12 rows, somewhat flattened, rather thick-walled, but not sclerotic cells. The parenchyma of the primary bark contains numerous groups of crystals, and scattered groups of roundish stone cells, with very thick walls, and accompanied by single rhombohedral crystals; it is free from secondary cork. The inner bark consists of medullary rays composed of two or three rows of thin-walled, somewhat radially elongated cells, and of broader bast-rays in which the parenchyma cells are coarsely dotted upon the radial and horizontal walls, and loosely united in a tangential direction; the bast-fibres form alternate groups of two or three rows, extending into few bast-rays, and are surrounded by crystal cells. The medullary paren-

U. S. The freshly fractured surface is colored red by solution of potassium hydroxide. According to the analysis of A. B. Prescott (*N. P.*, Feb. 1879), it contains a very bitter brown resin (which is colored a vivid purple-red by potassium hydroxide); a red resin; a light yellow resin; tannic, malic, and oxalic acids; a neutral crystallizable substance; and a volatile oil.² H. F. Meier and J. Le Roy Webber have pointed out in addition the presence of a ferment, glucose, and ammonia. According to these investigators, to the action of the ferment are attributed the unpleasant results attending the administration of "fresh bark;" "seasoned bark"—*i.e.*, such as has been kept a year or two—owes its valuable properties as a laxative, *free from griping*, to the fact that the ferment has exhausted itself; the laxative properties, they state, reside in the resins, and the tonic effects are due to the crystalline principle. (*A. J. P.*, 1888, 91.)³ Parke, Davis & Co., the introducers of this remedy, inform us that they always keep the bark two years before using it. Schwabe (*A. Pharm.*, 226, 569) identified *emodin*, or trioxymethylanthraquinone, as present, and stated that it was the active principle. Dohme and Engelhardt (*Proc. A. Ph. A.*, 1897, 193) have shown the analogy of cascara sagrada with *Rhamnus Frangula* by obtaining a glucoside to which they give the name of *purshianin*. This decomposes, yielding *emodin* and a dextro-rotatory non-fermentable sugar, while the frangulin of buckthorn yields *emodin* and *rhamnose* as the sugar. *Purshianin* forms brown-red needles, melting at 237° C. Dohme and Engelhardt failed to obtain in a pure form (*Proc. A. Ph. A.*, 1898, 340) the bitter principle of cascara sagrada. Le Prince (*C. R. A. S.*, 1892, 286) claimed to have obtained the active principle of cascara bark in a crystalline form, which he named *casarine*, his results are doubted by Jowett who believes that *casarine* and *purshianin* are impure forms of *emodin*. Jowett (*Proc. A. Ph. A.*, 1904, 288) in an exhaustive paper concludes that the active principle of cascara is contained in that portion of an alcoholic extract which is soluble in water and precipitable by lead subacetate and in that portion of the regenerated lead subacetate precipitate which is soluble in ethyl acetate.

chyma contains a crummy, lemon-yellow substance, which dissolves in water with a yellow color, and in cold potassium hydroxide solution with a dingy red color.

²The bark of *R. Wightii*, which is sold in the Indian bazaars, has been chemically investigated by David Hooper and found to contain substances similar to those contained in *R. Purshiana*. (See *P. J.*, Feb. 18, 1888.)

³*Tasteless preparations of cascara.*—It has long been known that the action of alkalies, lime, magnesia, ammonia, etc., upon cascara bark preparations diminished the bitterness without interfering with the laxative properties. B. E. Nelson (*Proc. A. Ph. A.*, 1904, 313) carefully examined the various methods which have been proposed and concludes that there is a slight loss of activity due to the action of the alkalies, but in the best preparations this is not sufficient to interfere with their usefulness. (See *Fluiddietroctum Rhamni Purshiana Aromaticum*, page 556; also *West. Drug.*, 1902, 496.)

Uses.—Cascara sagrada is an excellent laxative for use in *habitual constipation*. It is not to be employed as a purgative when a powerful impression is desired to be made. Its action closely resembles that of *Rhamnus Frangula*, but is more powerful and certain. In many cases of habitual constipation the continued use of the bark seems to produce a permanent beneficial effect upon the intestinal tract. Ordinarily a single dose may be given at bed time, but in some cases better results are obtained by exhibiting smaller doses after meals. The crude bark itself is never used medicinally, but usually in the form of the extract or fluidextract.

Dose, fifteen to thirty grains (1 to 2 Gm.).

RHUBARB

(rhē'ūm)

"The dried rhizome of *Rheum officinale* Baillon, *Rheum palmatum* Linné, and the var. *tanguticum* Maximowicz (Fam. *Polygonaceæ*), or probably other species of *Rheum*, grown in China and Thibet, and deprived of most of the bark and carefully dried." *U. S.* "The erect rhizome or so-called root of *Rheum palmatum*, Linn.; *Rheum officinale*, Baill.; and probably other species; collected in China and Thibet, deprived of more or less of its cortex, and dried." *Br.*

Rhei Radix, Br.; Rhubarb Root; Rhubarbe de Chine, *Fr. Cod.*; Rhubarbe, *Fr.*; Rhabarber, *G.*; Rabarbaro, *It.*; Ruibarbo, *Sp.*; Hainoung, *Chin.*; Schara-modo, *Thibet*.

Notwithstanding the length of time that rhubarb has been in use, it has not yet been determined from what precise plant the Asiatic drug is derived, the remoteness of the region where it is collected, and the jealous care with which the monopoly of the trade is guarded, having prevented accurate information.

The terms *rha* and *rheon*, from the former of which were derived the names *rhabarbarum* and *rhubarb*, and from the latter the botanical title *Rheum*, were applied by the ancients to a root which came from beyond the Bosphorus, and which is supposed, though upon somewhat uncertain grounds, to have been the product of *Rheum rhaponticum*, L., growing on the banks of the Caspian Sea and the Volga. This species was also at one time believed to be the source of the medicine now in use; but the true rhubarb has long been known to be wholly distinct from the Rhapontic, and derived from a different source. It was not until the year 1732 that any probable information was obtained as to its real origin. At that

time plants were received from Russia by Jussieu in France, and Rand in England, which were said to be of the species affording the genuine rhubarb, and were named by Linnæus, under this impression, *Rheum Rhabarbarum*, a title which has since given way to *Rheum undulatum*. Subsequently, Kaau-Boerhaave obtained from a merchant, who dealt in the rhubarb of Tartary, some seeds which he said were those of the plant producing the root sold by him. These, having been planted, yielded two species of Rheum, *R. undulatum*, and another which Linnæus named *R. palmatum*. Seeds transmitted by Mounsey from St. Petersburg to Hope, and planted in the botanic garden at Edinburgh, produced the latter species, and the same was also raised at Upsal from a root received by Linnæus from De Gorter, and was described in 1767 by the younger Linnæus, two years after the appearance of Hope's paper in the Philosophical Transactions. Thus far the evidence appears equally in favor of *R. palmatum* and *R. undulatum*. Colonel Przewalski has recently reasserted from personal observation that *R. palmatum* produces rhubarb; but the specimens of the root which he brought to St. Petersburg are stated by Dragendorff to be essentially different from true rhubarb. Claims have also been made from time to time for various other species of Rheum as sources of the drug. Pallas, upon exhibiting the leaves of *R. palmatum* to some Bucharian merchants, was told that the leaves of the rhubarb plant were entirely different in shape, and the description he received of them corresponded more closely with those of *R. compactum* than any other known species. Seeds of this plant were, moreover, sent to Miller from St. Petersburg as those of the true Tartarian rhubarb. Wallich, superintendent of the botanical garden at Calcutta, received seeds that were said to be those of the plant which yielded the Chinese rhubarb, growing on the Himalaya Mountains and the highlands of Tartary. These produced a species not previously described, which Wallich named *R. Emodi*, from the native title of the plant. It is the *R. australe* of Don and of Colebrooke, and has been ascertained to afford a root which, though purgative, is very unlike the official rhubarb. In 1867, French missionaries in South-eastern Thibet forwarded to Soubeiran of Paris, live specimens of a plant which they asserted to yield the true rhubarb, and Baillon subsequently described the flowering plant under the name of *R. officinale*. Its root resembles the true rhubarb, but the most careful cultivation has failed to obtain an identical product,¹ and it cannot yet be considered as settled how far the commercial drug is obtained from it.

¹ Senier found that, as raised in England, the root of *R. officinale* yielded less than half the percentage of extract obtained from the East Indian drug. In ten grain doses the extract was decidedly cathartic.

All the plants of this genus are perennial and herbaceous, with large branching roots, which send forth vigorous stems from four to eight feet or more in height, surrounded at their base with numerous very large petiolate leaves, and terminating in lengthened branching panicles, composed of small and very numerous flowers, resembling those of the *Rumex* or dock. There is some difficulty in arranging the species, in consequence of the tendency of the cultivated plants to form hybrids, and it is frequently impossible to ascertain to which of the wild types the several garden varieties are to be referred. Lindley, *Flora Medica*, states that *R. rhaponticum*, *R. hybridum*, and *R. compactum*, and their hybrids, are the common garden rhubarbs.

R. officinale, Baillon—*B. & T.* 213—is described in the *Pharmacographia* "as a perennial, noble plant, resembling the common garden rhubarb, but of larger size. It differs from the latter in several particulars: the leaves spring from a distinct crown rising some inches above the surface of the ground; they have a subcylindrical petiole, which, as well as the veins of the under side of the lamina, is covered with a pubescence of short erect hairs. The lamina, the outline of which is orbicular, cordate at base, is shortly 5- to 7-lobed, with the lobes coarsely and irregularly dentate; it attains 4 to 4½ feet in length, and rather more in breadth. The first leaves in spring display before expanding the peculiar metallic red hue of copper."

Besides the species already mentioned, *R. leucorrhizum*, growing in the Kirgheez desert in Tartary, *R. capsicum*, from the Altai Mountains, *R. webbium*, *R. speciforme*, and *R. moorcraftianum*, natives of the Himalaya Mountains, and *R. crassinervium* and *R. hybridum*, cultivated in Europe, but of unknown origin, yield roots which have either been employed as purgatives or possess properties more or less analogous to those of official rhubarb, though they have not entered into general commerce. In Java, the root of an indigenous species is used as a purgative. According to the analysis of J. H. Schmidt, it contains more chrysophanic and emodin, and less chrysophanic and rheo-tannic acids, than does the official drug.¹

Rhubarb is produced abundantly in the elevated lands of Tartary, about the lake Koko Nor, and is said to be cultivated in the neighboring Chinese province of Shen-see, and in that of Se-chuen. From these sources it is generally supposed that our supplies of Russian and Chinese rhubarb were exclusively derived; but the root is also collected in Bootan and Thibet, on the north of the Himalaya

Mountains, and it is probable that the plant pervades the whole of Chinese Tartary. It flourishes best in a light sandy soil. It is stated by Bell, who, on a journey from St. Petersburg to Pekin, had an opportunity of observing it in a growing state, that it is not cultivated by the Tartars, but springs up spontaneously, in tufts, wherever the seeds have fallen upon the heaps of loose earth thrown up by the marmots. In other places the thickness of the grass prevents their access to the soil. The root is not considered sufficiently mature for collection until it has attained the age of six years. It is dug up twice a year in Tartary, in the spring and autumn; in China not till the winter. After removal from the ground, it is cleaned, deprived of its cortical portion and the smaller branches, and then divided into pieces of a convenient size. These are bored with holes, and strung upon cords to dry, according to Bell, about the tents and on the horns of sheep; according to Sievers, under sheds, by which the rays of the sun are excluded, while the air has free access. The Chinese are said first to place the pieces on a stone slab heated by fire beneath, and afterwards to complete the drying process by exposing them to the sun and air. In Bootan the roots are hung up in a kind of drying room, in which a moderate and regular heat is maintained. Much time and attention are devoted to the preparation of the root, and Sievers states that a year sometimes elapses from the period of its collection before it is ready for exportation. A large proportion of its weight is lost in drying, according to some accounts four-fifths, according to others not less than seven-eighths. It is probably in order to favor the drying that the bark is removed. Rhubarb which has been dried by artificial heat is known commercially as high dried and often can be recognized by its more or less blackened surface, and its heavy, scarcely fragrant odor. The trade in rhubarb is said to have formerly centred in the Chinese town of Si-nin, where a Bucharian company or family was established which possessed a monopoly of this trade in consideration of a tribute paid to the government. At present rhubarb is chiefly purchased for the European trade at the town of Hankow, on the upper Yang-tse, the yearly export reaching, it is said, over 5000 peculs (pecul = 133.33 lbs.). There were formerly two varieties of Asiatic rhubarb, the Russian and the Chinese, but at present little or no rhubarb finds its way overland to Europe. As long back as 1687, the Russian government subjected the export of rhubarb from China into Russia to official surveillance, and finally monopolized the trade entirely. At Kiakhta a very rigorous inspection of the drug was enforced, the selected pieces being finally sewed into linen sacks pitched and coated with hide. All the pieces which did not pass examination were committed to the flames, and the remainder was sent to St. Petersburg. This variety was some-

¹ According to Aitchison (*Nature*, July 9, 1885), a rhubarb plant has been found in Northern Afghanistan in which there are usually only three enormous root leaves four feet long and five feet broad, lying flat upon the ground. The fruit is large and of a brilliant scarlet. The root is said to possess purgative properties, but the fruit is preferred, and is given in the form of a decoction.

times called *Turkey rhubarb*, from the circumstance that it was formerly derived from the Turkish ports, whither it is said to have been brought from Tartary by caravans through Persia and Anatolia. Inferior parcels of the root, which could not pass the inspection of the Russian authorities, were said to enter Russia by Tashkend, and to be known to the druggists of that country by the name of *Tashkend rhubarb*. As Russian rhubarb no longer occurs in commerce, the description of it is given in a foot-note.¹

CHINESE RHUBARB (*India Rhubarb*, *Rheum Sinense* vel *Indicum*) is in cylindrical or roundish pieces, sometimes flattened on one or both sides, of a dirty brownish-yellow color externally, appearing as if the cortical portion of the root had been removed by scraping, and the surface rendered smooth and somewhat powdery by attrition. The best pieces have a rather close and compact texture, and, when broken, present a ragged uneven surface, variegated with intermingled shades of dull red, yellowish, and white, which are sometimes diversified or interrupted by darker colors, and especially marked with dark lines so arranged as to form an internal ring of star-like spots. The pieces are generally perforated with small holes, intended for convenience of suspension during the drying process, and portions of the suspending cord are not unfrequently found remaining in the holes. According to Elborne (*P. J.*, xv. 497), Chinese rhubarb is really divided into two varieties, which are respectively the product of *R. palmatum* and *R. officinale*.²

¹The pieces of Russian rhubarb were irregular and somewhat angular, appearing as if the bark had been shaved off longitudinally by successive strokes of a knife, and a portion of the interior substance removed with each shaving. They had a cleaner and fresher appearance than the Chinese, and their color both internally and externally, though of the same general character, was somewhat more lively. They were less compact and heavy, and were cut with less facility, owing to their giving way before the knife. Another distinction is the character of the perforations, which in the Russian rhubarb were large, frequently reaching only to the centre, and evidently made for the purpose of inspection, while in the Chinese they are small, penetrate completely through the pieces, and are intended for the passage of a suspending cord. The taste and odor of the former closely resembled those of the latter, except that the Russian was rather more aromatic. There is the same crackling under the teeth, and the same yellow stain imparted to the saliva; but the color of the powder in this variety was a bright yellow, without the brownish tinge exhibited by the Chinese. When thin slices, previously boiled in water, were examined by the microscope, they exhibited numerous clusters of minute crystals of calcium oxalate. Quekett found between 35 and 40 grains of them in 100 grains of the root. They were observed in both Russian and Chinese rhubarb. For further information as to the varieties of Russian rhubarb, see *A. J. P.*, 1867, p. 212, or abstract in 14th edition *U. S. D.*

²In former editions of this work a variety of rhubarb imported from Canton has been noticed, which was evidently prepared, before leaving China, so as to resemble the Russian, having an angular surface as if pared with a knife. The pieces were obviously selected with great care, as they were remarkably free from defects. But in most of those which came under our notice the small penetrating hole was observable which characterizes the Chinese rhubarb, though it had in some instances been filled with the powdered root, so as in some measure to conceal it. Besides, the colors were not quite so bright as those of Russian rhubarb. This

the first variety has a red-grained fracture with white lattice-work veins, while the second variety has a longitudinal ramification of white veins with a black-grained fracture. Chinese rhubarb has a peculiar somewhat aromatic odor, and a bitter, astringent taste, is gritty when chewed, imparts a yellow color to the saliva, and affords a yellowish powder with a reddish-brown tinge. With the pieces of good quality others often come mingled, defective from decay or improper preparation. These are usually lighter, and of a dark or russet color. Like all the other varieties of rhubarb, this is liable to be attacked by worms, and in almost every large parcel pieces may be found which have suffered from this cause.³

Chinese rhubarb is the only kind recognized by the U. S. P., and is officially described as "subcylindrical, barrel-shaped, conical, plano-convex or irregularly formed pieces, frequently with a large perforation; hard and moderately heavy; 5 to 15 Cm. long, 4 to 8 Cm. in diameter; externally mottled with alternating striae of light brown parenchyma cells and dark brown medullary rays, occasionally with reddish-brown cork patches and small radiate scars of fibrovascular tissue, smooth and sometimes covered with a bright brownish-yellow powder; fracture somewhat granular, presenting a peculiar marbled appearance; odor characteristic; taste bitter, astringent; gritty when chewed. Powder bright orange-yellow, becoming red with alkalies, containing rosette-shaped crystals of calcium oxalate, which are from 0.50 to 0.100 Mm. in diameter, and spherical starch grains from 0.005 to 0.020 Mm. in diameter, either single or 2- to 4-compound." *U. S.*

EUROPEAN RHUBARB.—In various parts of Europe, particularly in England, France, Belgium, and Germany, the rhubarb plants have been cultivated for many years, and considerable quantities of the root were at one time brought into the market. At present it appears not to be imported.

English Rhubarb.—This formerly came in two forms. In one the root was cut and perforated in imitation of the Russian. The

is undoubtedly the variety described by Perelra, under a distinct head, as the *Dutch-trimmed* or *Batavian rhubarb*, and considered by him as probably Bucharian or Russian rhubarb of inferior quality, sent by the way of Canton. A sufficient proof, we think, that this is not the case is the presence in most pieces of the small penetrating hole, occasionally filled with the remains of the cord, and in some pieces almost shaved away in the paring process. We have never seen such a hole in any piece of true Russian rhubarb, which does not appear to be strung up like the Chinese when dried.

Under the title of *Canton stick rhubarb*, Perelra describes a variety of which small quantities have been imported from Canton into London. It closely resembles the English stick rhubarb, and is supposed to be derived from the branches of the root of the plant which yields the true Chinese rhubarb.

³Rhubarb is prone to be attacked during storage by the caterpillar of a small grayish-white moth, whose species does not seem to have been determined. According to the experiments of Sawyer and Ferguson, rhubarb which has been attacked is best treated on a large scale by a combination of heat and exposure to the vapor of sulphur. Insect-powder had no effect upon the worms. For details of method, see *P. J.*, xx. 1889.

pieces were of various shape and size, sometimes cylindrical, but more commonly flat, or somewhat lenticular, and of considerable dimensions. In the other, the so-called *stick rhubarb*, the pieces were somewhat cylindrical, five or six inches long by an inch or less in thickness, and more or less irregular upon the surface, as if they had shrunk unequally in drying. English rhubarb (from *Rheum rhaponticum*) is lighter than the Asiatic, more spongy, and often somewhat pasty under the pestle. It is redder, and when broken exhibits a more compact and regular marbling, the pinkish lines being arranged like rays from the centre towards the circumference. The "star-like spots" are either wanting or very few and scattered. The powder also has a deeper reddish tint. The odor is feeble and less aromatic than that of the Asiatic varieties; the taste is astringent and mucilaginous, with little bitterness, and the root, when chewed, scarcely feels gritty between the teeth, and but slightly colors the saliva. Few crystals of calcium oxalate are discoverable by means of the microscope. Much English rhubarb is obtained from *R. officinale*, and is put on the market in flat, concave, and convex pieces weighing from three to four ounces each. Externally the convex surface has deep longitudinal furrows and a longitudinal ramification of conspicuous veins, giving rise to an appearance of net-vein markings. In the centre of the concave surface is a small hole similar to that formerly seen in Russian rhubarb. On the inner surface the stellate markings resemble very closely those found in the East Indian rhubarb. The fracture of this form is not red, but shows a whitish parenchymatous tissue with blackish veins. The roots are distinctly gritty when chewed. When rapidly grown in rich soil, English rhubarb is lighter, more spongy, and less active than when slowly grown without high cultivation. It is probable that the powder is used to adulterate that of true Asiatic rhubarb, but of this we have no positive evidence.

French Rhubarb. *Rhapontic Rhubarb.* *Crimea Rhubarb.*—The rhubarb produced in France is, according to Guibourt, chiefly from *R. rhaponticum*, *R. undulatum*, and *R. compactum*, that of *R. palmatum*, which most closely resembles the Asiatic, having been found to degenerate so much as not to be a profitable object of culture. Most of the French rhubarb is produced in the neighborhood of L'Orient, in the department of Morbihan, and the spot where it grows has, from this circumstance, received the name of *Rheumpole*. Two kinds were described by Guibourt, both under the name of *Rhapontic root*,¹—one proceeding from the *R. rhaponticum*, growing in the gardens in the environs of Paris; the other, from this and the two other species above mentioned,

cultivated at Rheumpole; but, according to the *Pharmacographia*, the cultivation in France has been almost entirely abandoned.²

Choice of Rhubarb.—In selecting good rhubarb, without reference to the commercial variety, those pieces should be preferred which are moderately heavy and compact, of a lively color, brittle, presenting when broken a fresh appearance, with reddish and yellowish veins intermingled with white, of an odor decidedly aromatic, of a bitter and astringent not mucilaginous taste, feeling gritty and staining the saliva yellow when chewed, and affording a powder either bright yellow, or yellow with but a slight reddish-brown tinge. When very light, rhubarb is usually rotten or worm-eaten; when very heavy and compact, it is of inferior species, culture, or preparation. Rotten, worm-eaten, or otherwise inferior rhubarb is often powdered, and colored yellow with turmeric, and the shavings left when Chinese rhubarb is trimmed for powdering, or to imitate the Russian, are applied to the same purpose.³ The stellate markings observed in the cut or broken surface of the Chinese rhubarb has been believed by various pharmacologists to be of great practical value in determining the true character of the rhizome and especially in enabling a distinction between the Chinese and European rhubarb to be made. There has been a general concurrence with the statements of Tschirch that the star spots are never present in the root, occurring only in the rhizome. In an elaborate re-examination of this subject by Jakabhasy, however, the star spots were found in the root as well as in the root stock and also in the European as well as in the Asiatic rhubarb. Nevertheless, Jakabhasy states that it is possible to distinguish the two rhubarbs

¹ Besides the varieties of rhubarb above described, others are noticed by writers. Pallas speaks of a *white rhubarb*, brought to Kiakhta by the Bucharian merchants who conveyed to that place the drug for Russian commerce. It was white as milk, of a sweet taste, and equal to the best rhubarb in quality. It was supposed to be the product of *R. leucorrhizum*. At present, however, it is unknown in St. Petersburg. The *Himalaya rhubarb* is produced by *R. australe*, and other species mentioned in the text as growing in the Himalaya Mountains. According to Royle, it makes its way to the lower countries in Hindustan, where it sells for one-tenth of the price of the best rhubarb. Twining tried it in the Hospital at Calcutta, and found it superior as a tonic and astringent to Russian rhubarb, and nearly equal to it in purgative power. A variety known in Russia as *Bucharian rhubarb*, differing from the variety which we called Russian, and which is known in Russia as Chinese rhubarb, is imported into that country from Tartary, and reaches St. Petersburg by Nizhni-Novgorod. Parcels of it are said also to reach Vienna, by the way of Brody in Galicia. Still another variety is that called *Siberian rhubarb*, which is known in Russia by the name of *Siberian Rhapontic root*. As these are inferior kinds, and probably never reach our markets, we have not thought it necessary to discuss them in detail. For further information, see A. J. P. (xviii. 63 and 123).

² It has been stated by Bonl that Chinese rhubarb yields from 20 to 25 per cent. of ash, the European rhubarb from 8 to 11 per cent., the difference being due to the excess of calcium oxalate in the Chinese rhubarb. Kremel, however, finds that the amount of ash in different species of rhubarb fluctuates too greatly to be of practical value in the determination of the source, even the Chinese root varying between 10 and 28 per cent.

³ The *rhapontic root* differs in section from true rhubarb by its distinctly radiated structure, unbroken by the peculiar arrangement (star-like spots) of the vascular tissue which occurs in true rhubarb.

by the fact that in the European Rhubarb the star spots occur in greater number on the longitudinal section while in the Chinese rhubarb they are present on the transverse section, where they form a circle. He believes also that the superabundance of starch and the lack of crystals in the star spots are diagnostic of the European drug. When the rhubarb is powdered these characteristics are not available, under which circumstances the percentage of ash seems to be valuable. The Chinese rhubarb, unless of very inferior quality yields from 8 to 25 per cent.; the European 1.3 to 6 per cent. of ash. According to Jakabhazy, Shensi is the best, Shanghai the poorest, and Canton the intermediate variety of Chinese rhubarb. Of the European the English is the most, the French next, and the Austrian the least active. Powdered rhubarb should contain numerous roundish starch granules, about .026 Mm. in diameter, large associated calcium oxalate crystals, and small, somewhat stellate, chrysophanic acid crystals, besides parenchymatous cells, pitted vessels, and other ordinary debris of root tissue.¹

Chemical Properties.—Rhubarb yields all its activity to water and alcohol. The infusion is of a dark reddish-yellow color, with the taste and odor of rhubarb, and the residue, after sufficient maceration, is whitish, inodorous, and insipid. By long boiling the virtues of the medicine are impaired. The first examination of rhubarb yielding results of value was that of Schlossberger and Döpping. Besides extractive, tannic and gallic acids, sugar, starch, pectin, lignin, calcium oxalate, and various inorganic salts, they discovered three coloring principles, holding an intermediate place between resin and extractive matter, being freely soluble in alcohol, and slightly so in water. Two of these were uncrystallizable, and denominated *brown resin* and *red resin*, or *phæoretin* and *erythroretin*; the other, crystallizable in granular crystals, and identical with *chrysophanic acid*, previously discovered by Rochleder and Heldt in the yellow lichen, or *Parmelia parietina* of Sprengel. Chrysophanic acid crystallizes in golden-yellow needles or plates melting at 102° C., and is soluble in ether, alcohol, or benzene. Alkalies also dissolve it, forming fine dark red solutions. Its

formula is $C_{15}H_{10}O_4$, and it is now recognized as a derivative of anthracene, $C_{14}H_{10}$, and as closely related to alizarine, $C_{15}H_8O_4$. It bears to methyl-anthracene, $C_{14}H_8(CH_3)$, the same relation that alizarine bears to anthracene. Hence, on distilling it with zinc dust, methyl-anthracene is formed from it by reduction. (See *Chrysarobinum*.)

De La Rue and Müller (*J. Chem. S.*, x, 298) extracted from rhubarb an allied substance, *emodin*, which crystallizes in orange-colored prisms. (See p. 116; also *Emodin*, PART II.) Its formula is $C_{15}H_{10}O_5$, and it is a trioxymethyl-anthraquinone. The relations of both this compound and chrysophanic acid to alizarine and anthracene will be better shown by writing their molecular formulas, as follows:

Kubli (*Ph. Z. R.*, 6, p. 603) obtained results both confirmatory and explanatory of those already given. He found a glucoside, *chrysophan*, $C_{27}H_{30}O_{14}$, which, under the influence of dilute acids or ferments, splits up into chrysophanic acid and sugar, according to the reaction

$C_{27}H_{30}O_{14} + 2H_2O = C_{15}H_{10}O_4 + 2C_6H_{12}O_6$

also a characteristic tannic acid, *rheo-tannic acid*, $C_{26}H_{26}O_{14}$, which is decomposed by dilute acids into *rheumatic acid*, $C_{20}H_{16}O_8$, and sugar. Chrysophan is a yellowish powder, abundantly present in rhubarb, soluble in water or alcohol, not in ether; rheo-tannic acid is a reddish brown powder, sparingly soluble in cold water. Kubli found further a colorless neutral compound, sparingly soluble in hot water, of the formula $C_{10}H_{12}O_4$, which he did not name. He stated that chrysophanic acid is not found in rhubarb, but is produced when the root is digested in water through the breaking up of the glucoside *chrysophan*, probably under the action of a ferment. This ferment he believes to be soluble in water, but insoluble in alcohol, and that on this account an alcoholic extract of the root can be evaporated without the formation of chrysophanic acid. On the other hand, it is to the presence of this ferment that he attributes the progressive deposition of chrysophanic acid from an extract of rhubarb prepared with diluted alcohol. (*Ph. Z. R.*, xxiv, 193.) O. Hesse (*Proc. A. Ph. A.*, 1896, 549) found in addition to chrysophanic acid, $C_{15}H_8O_2(OH)_2$, and emodin, $C_{15}H_7O_2(OH)_3$, a third crystalline principle, which he named *rhein*, and ascribes to it the formula $C_{15}H_6O_2(OH)_4$. Hesse calls attention to the relation these formulas bear to one another. Rhein forms microscopic yellowish-brown scales, is insoluble in water, ether, and benzene, but sparingly soluble in alcohol. It dissolves readily in aqueous solutions of the alkalies and alkaline carbonates, forming deep purple-red solutions. Hesse also finds an amorphous resinous substance, upon which, he states, the entire activity of rhubarb depends. Dragendorff

¹ The powdered raphanotic root seems microscopically indistinguishable from powdered rhubarb; but, according to M. E. Billot, raphanotic root, even when used to adulterate powdered rhubarb, may be detected as follows. On a little of the suspected powder, upon a plate, let fall two or three drops of oil of anise, oil of fennel, or other essential oil; then add magnesia, and rub the mixture well for three or four minutes. If the powder be pure, it will remain yellow; but if it contain the smallest quantity of the French raphanotic root, it will assume a reddish tint, varying from a salmon to a bright rose color, according to the quantity of the impurity present. (See *A. J. P.*, May, 1860, 224.) The *Rumex hymenosepalus*, which is said to be used as an adulterant of powdered rhubarb, according to L. E. Sayre, may be detected by the character of the starch granules, which are long and slender, with a branching hilum extending along their greater diameter.

states that from 11 to 17 per cent. of arabic acid and pectose are present in rhubarb. Hunkel (*P. Archiv.* Nov. 1900, 201) reviewed the investigations of various chemists and isolated *tanoid* by the process of Löwe and a phenolic body (unnamed) which had not been previously described.

The most important researches upon the constituents of rhubarb were made by Tschirch and Heuberger (*A. Pharm.*, Nov. 21, 1902, 596, 630, and *Ph. Ztg.*, Aug. 3, 1904, 651). Their conclusions are that rhubarb contains primarily two classes of substances. 1. *Tannoglucosides*; 2. *Anthraglucosides*. These two classes cannot be sharply separated from each other and are therefore associated together in all extractions. Both of these are characterized by their ready decomposition and conversion into secondary products, such conversion resulting even during the treatment of the drug with ordinary solvents. Thus, the ether extraction has been found to contain the products of the hydrolysis of the anthraglucosides, namely, chrysophanic acid, emodin and rhein. It is however not proven (indeed not even probable) that the tannoglucosides combine with the anthraglucosides to form so-called double glucosides. On the contrary, the indications are that these two classes of glucosides occur beside each other; furthermore, the relatively large quantity of tannoglucosides and their hydrolytic products is noteworthy and that, therefore, the activity of rhubarb is not attributable solely to the anthraglucosides; but the activity of the latter must be materially modified by that of the tannoglucosides. To what degree the primary tanno- and anthraglucosides have become hydrolyzed in the drug itself, it is difficult to determine; it is certain, however, that the drug contains a considerable quantity of free oxymethylantraquinones, while it is probable that the formation of the secondary glucosides results during the extraction and manipulation of the extract.

Tschirch sums up the results of the investigation as follows: *Aweng's Double Glucoside* is in its essentials identical with tannoglucoside, but contains some anthraglucoside. *Aweng's Frangulic Acid* is a secondary product of the decomposition of tannoglucoside, containing variable quantities of anthraglucoside as impurity. *Kubli's Rheumtannic Acid* and *Hunkel's Tanoid* are identical with tannoglucoside, but less pure. *Kubli's and Hunkel's Rheum Acid* is identical with *rheum red*, and therefore a product of the hydrolysis of tannoglucoside. *Schlossberger and Dopping's Aporetin* and *Phaeoretin* are impure, difficultly soluble tannoglucoside. *Erythreoretin* is a mixture of chrysophanic acid, emodin and rhein. *Garot's Erythrose* is chrysamic acid. *Rhein*, yielding only a diacetyl derivative, cannot be regarded as being tetraoxymethyl-antraquinone. It has the composition $C_{15}H_8O_6$ (not $C_{15}H_{10}O_6$, Hesse) which formula corresponds to a methylene ether of a tetraoxyantraquinone.

Dragendorff's, Greenish's and Elborne's Cathartic Acid is an impure tannoglucoside, containing anthraglucosides and some albuminoid substances. *Gilson's Chrysophan* belongs to the anthraglucosides. *Aweng's Secondary Glucosides* are secondary, mostly difficultly soluble hydrolytic products of the primary tanno- and probably also of the anthraglucosides.

Finally, Tschirch determined that rhubarb contains no resins whatever; that the rheo-tannoglucosides and their products of decomposition and hydrolysis are devoid of purgative activity, and that such activity is due solely to the anthraglucosides and their derivatives. Rhubarb contains no other body besides the latter that has peristaltic effect on the intestinal tract.

As regards the rheo-tannoglucoside, its medicinal activity is confined to the tonic and mildly astringent effect produced on administering the drug. Tschirch (*Ph. Ztg.*, Aug. 3, 1904, 651) recommended a method for assaying rhubarb based on the volumetric estimation of the free oxymethylantraquinones, dependent on the ease with which the anthraglucosides can be hydrolyzed with sulphuric acid. See also *Proc. A. Ph. A.*, 1905, 627.

There are other interesting principles in rhubarb. Some have been disposed to ascribe its odor to a volatile oil, but this has not been isolated. The calcium oxalate is interesting from its quantity, and from the circumstance that, existing in distinct crystals, it occasions the grittiness of the rhubarb between the teeth. The proportion seems to vary exceedingly in different specimens. According to Scheele and Henry, it constitutes nearly one-third, and Queckett found between 35 and 40 per cent., while Brandes obtained only 11, Schrader only 4.5 parts in the hundred, and Dragendorff, in five samples analyzed, from 1.2 to 5.6 per cent. Little or no difference of composition has been found between the Russian and the Chinese rhubarb. The European contains but a small proportion of calcium oxalate, and is therefore less gritty when chewed. It has, however, more tannin and starch than the Asiatic.

When powdered rhubarb is heated, odorous yellow fumes rise, which are probably in part the vapor of chrysophanic acid. Its infusion is reddened by the alkalies, in consequence of their union with this acid, and their reaction on the other coloring principles. It yields precipitates with gelatin, most of the acids, ferric salts, lead acetate, mercurous nitrate, silver nitrate, stannous chloride, lime water, and solutions of quinine. Nitric acid occasions at first a turbidness, and afterwards the deposition of a yellow precipitate. The substances producing precipitates may be considered as incompatible with the infusion.¹

¹For a method of detecting the presence of turmeric in powdered rhubarb by the influence of chloroform on the coloring principles of each of these substances, and of distinguishing through the same agency between the true Chinese rhubarb and that of European origin, the reader is referred to a

Uses.—The medicinal properties of rhubarb are peculiar and valuable. Its most remarkable singularity is the union of a cathartic with an astringent power, the latter of which, however, does not interfere with the former, as the purgative effect precedes the astringent. It is also tonic and stomachic, invigorating, in small doses, the process of digestion. It is not probable that these properties reside in a single proximate principle, but in a combination. In its purgative operation rhubarb is moderate, producing fecal rather than watery discharges, and appearing to affect the muscular fibre more than the secretory function. It sometimes occasions griping. Its coloring principle is absorbed, and may be detected in the urine. By its long-continued use the perspiration, especially that of the axilla, is said to become yellow, and the milk of nurses cathartic. It gives a yellow color to the alvine discharges. The conditions of disease to which it is applicable may be inferred from its peculiar properties. When the stomach is enfeebled, or the bowels relaxed, at the same time that a gentle cathartic is required, rhubarb, as a rule, is preferable to all others. Hence its use in *dyspepsia* attended with constipation, in *diarrhœa* when purging is indicated, in the secondary stages of *cholera infantum*, in *chronic dysentery*, and, indeed, whenever mild purgation is needed in an enfeebled subject. Magnesia is often an excellent associate in disorders of the stomach and bowels. By combination with other cathartics, rhubarb frequently acquires additional activity, while it gives increased efficiency to the associated substance. A mixture of calomel and rhubarb is a brisk and powerful cathartic, often used at the commencement of *bilious fevers*. As a rule, rhubarb is not applicable to cases attended with much inflammatory action. Its griping effect may be counteracted by combining it with aromatics.

By the roasting of rhubarb its cathartic property is diminished, probably by the volatilization of the purgative principle, while its astringency remains unaffected. When so treated it is termed *torrefied rhubarb*. This mode of treatment has been sometimes resorted to in cases of *diarrhœa*. By long boiling the same effect is said to be produced.

Powdered rhubarb has been usefully applied to indolent and sloughing ulcers. It is said to have proved purgative when sprinkled over a large ulcerated surface, and the same effect is asserted to have been produced by rubbing it, mingled with saliva, over the abdomen.

European rhubarb must be administered in double or treble the dose of true rhubarb to produce an equal effect. Few medicines are used in a greater variety of forms. It is most effectual in substance. It is frequently given in the shape of pill, combined with an equal

proportion of soap when its laxative effect is desired. The infusion is much used in cases of delicate stomach, and is peculiarly adapted to children. The syrup, tincture, and fluidextract are also useful preparations. They are all official.

Dose, as a purgative, from twenty to thirty grains (1.3 to 2.0 Gm.); as a laxative and stomachic from five to ten grains (0.32 to 0.65 Gm.).

Corn Poppy, Corn Rose; Coquellcot, *Fr. Cod.*; Pavot rouge, *Fr.*; Wilder Mohn, Klapperrose, Klatschrosen, *G.*; Rosolaccio, *It.*; Amapola (Flor de), *Sp.*

Papaver Rhœas, Willd., *Sp. Plant.* ii. 1146; *B. & T.* 19.—The red or corn poppy is distinguished by its hairy stem, which is branched, and rises about a foot in height, by its incised pinnatifid leaves, by its urn-shaped capsule, and by the full, bright, scarlet color of its petals. It is a native of Europe, where it grows wild in great abundance, adorning especially the fields of grain with its brilliant flower. It has been naturalized in this country.

Its capsules contain the same kind of milky juice as that found in *P. somniferum*, and an extract has been prepared from them having the properties of opium; but the quantity is too small to repay the trouble of its preparation. Filhol has shown that the extract contains morphine, but in a proportion exceedingly minute compared with that in which it exists in opium. (*J. P. C.*, ii. 513.) The petals are the official portion. They have a narcotic odor, and a mucilaginous, slightly bitter taste. By drying, they lose their odor, and assume a violet-red color. Chevallier believed that he had detected a very minute proportion of morphine in an extract obtained from them; but Atfield seems to have determined satisfactorily the non-existence of morphine in the petals, having sought this alkaloid by three different processes, using a pound of the petals in each experiment, and failed to detect the least evidence of its presence. (*P. J.*, Oct. 1873, p. 291.) Their operation on the system is exceedingly feeble, and they are valued more for their beautiful scarlet color, which they communicate to water, than for their medicinal virtues. According to Leo Meier, the coloring

paper, by W. L. Howle, contained in *A. J. P.* (Jan. 1874, 16), from *P. J.* (Nov. 15, 1873); see also *P. J.*, 1898, 126.

principles of the flowers are two acids, which he denominates *rhæadic* and *papaveric acids*. (See *A. J. P.*, xviii. 211.) A syrup is prepared from them, which was formerly prescribed as an anodyne in catarrhal affections, but is now little esteemed except for its color.

An alkaloid was discovered in this species of poppy by O. Hesse, who proposed to name it *rhæadine*. It seems to pervade all parts of the plant, from which, as the first step in its preparation, an aqueous extract is prepared. This is treated with sodium carbonate, and repeatedly agitated with ether; the ethereal liquid is shaken with a solution of sodium bitartrate, and the mixture is precipitated by ammonia. The precipitate is washed with cold water, dried, and boiled with alcohol, by which coloring matter and another alkaloid in small quantity, probably thebaine, are removed. The residue, consisting mainly of *rhæadine*, is purified by combining it with acetic acid, treating with animal charcoal, and precipitating with ammonia. The alkaloid is in small white prismatic crystals, tasteless, fusible at 232.2° C. (450° F.), becoming brown at the same temperature and partially subliming. It is almost insoluble in water, alcohol, ether, chloroform, benzene, ammonia, solution of sodium carbonate, and lime water, but is dissolved by dilute acids, which produce colorless solutions. Its composition is represented by the formula $C_{21}H_{21}NO_5$. It does not appear to be poisonous. Hydrochloric and sulphuric acids, moderately concentrated, decompose and dissolve it, with the production of a purple color, which disappears under the action of the alkalies, but is restored by acids. One part of the alkaloid so treated produces a purple color with 10,000 parts of water, rose color with 20,000 parts, and a perceptible redness with 800,000 parts. This change is dependent upon the liberation from the *rhæadine* of a red coloring matter, while the isomeric *rhæagenine* remains. This forms small white tasteless prisms, which fuse at 223° C. and do not sublime, but are decomposed at higher temperatures. This is a very delicate test, by means of which the alkaloid may be detected in all parts of *Papaver Rhæas*, in the ripe capsules of the opium poppy, and in opium itself. It is said also to exist in *Merek's porphyroxine*. (*A. J. P.*, 1867, p. 122.) According to Hesse, the milky juice also contains *meconic acid*.

RHUS GLABRA. U. S.

RHUS GLABRA

(rhūs glā'bra)

"The dried fruit of *Rhus glabra* Linné (Fam. *Anacardiaceæ*)." U. S.

Rhus Glabrum, U. S. 1870; Slek, Scarlet, White, Sumach, Shoe-make, Vinegar Tree; Sumac, Fr.; Sumach, G.

Rhus glabra, L., *Sp. Pl.* (1753) 265; Willd., *Sp. Plant.* i. 1478.—This species of *Rhus*, called variously *smooth sumach*, *Pennsylvania sumach*, and *upland sumach*, is an indigenous shrub from four to twelve feet or more in height, with a stem usually more or less bent, and divided into straggling branches, covered with a smooth, light gray, or somewhat reddish bark. The leaves are upon smooth petioles, and consist of many pairs of opposite leaflets, with an odd one at the extremity, all of which are lanceolate, acuminate, acutely serrate, glabrous, green on their upper surface, and whitish beneath. In the autumn their color changes to a beautiful red. The flowers are greenish red, and disposed in large, erect, terminal compound thyrses. The fruit is in clusters of small crimson berries, which are officially described as "flattened-ovoid, 3 to 4 Mm. in diameter, externally deep crimson, glandular-tomentose; endocarp light yellow, smooth, shiny, enclosing a single seed; inodorous; taste acidulous and astringent." U. S.

The shrub is found in Canada and almost all parts of the United States, growing in old neglected fields, along fences, and on the borders of woods. The flowers appear in July, and the fruit ripens in the early part of autumn. The bark and leaves are astringent, and are largely used, especially the leaves, in tanning leather and in dyeing. The sumach for the manufacture of extract for tanners' use is largely cultivated in Virginia, where the annual crop reaches from 7000 to 8000 tons, and is collected at any time between the first of July and the appearance of frost. W. J. Watson found, in the bark of the root, albumen, gum, starch, tannic and gallic acids, caoutchouc, resin, coloring matter, and evidences of volatile oil. (*A. J. P.*, xxv. 194.) Excrecences are produced under the leaves resembling galls in character, and containing large quantities of tannic and gallic acids. These have been used as a substitute for the imported galls by Walters of New York, who thought them in every respect preferable. They may be collected at little expense, as they are produced very abundantly, especially in the Western States. From the experiments of Stenhouse, it appears that the tannic acid of sumach is identical with that of galls, being, like it, resolved, under the influence of sulphuric acid, into glucose and gallic acid, and this change is supposed to take place spontaneously in sumach when long kept. (*Ibid.*, xxxiv. 252.)

The percentage of tannin in Virginia sumach rises at times as high as 27 per cent., but falls a few per cent. below this as the season advances. Samples of leaves gathered along the Mississippi near Dubuque, Iowa, in July and August, yielded 16.36 per cent. and 15.75 per cent. respectively. (*A. J. P.*, 1888, p. 389.) The proportion of tannic acid in the European sumach falls from 6 to 8 per cent. below the percentage of the Virginia sumach, yet the European is much preferred by tanners and

dyers. By using Sicilian sumach it is possible to make the finer white leathers so much used for gloves and fancy shoes, while by the employment of the American product the leather has a disagreeable yellow color, apparently due to a coloring matter, which, according to Loewe, consists of quercitrin and quercetin, and exists in larger quantity in the American than in the Sicilian drug. Enormous quantities of a dark-red, semi-fluid, bitter, astringent extract are prepared in Virginia from sumach, and used both in America and in Europe. It is said to contain from 25 to 30 per cent. of tannin.

Henry Trimble collected some galls from the leaves of *R. glabra* and found that they contained 61.70 per cent. of tannin, reckoned on the weight of the air-dried galls, or 70.90 per cent. of the weight of absolutely dry material. (*A. J. P.*, 1890, p. 564.)

The berries have a sour, astringent, not unpleasant taste, and are often eaten by the country people with impunity. According to Cozzens of New York, the malic acid is contained in the pubescence which covers their surface, as when it is washed away by warm water the berries are wholly free from acidity. W. B. Rogers found the acid to be combined with lime,¹ as acid calcium malate. W. J. Watson ascertained that free malic acid and acid calcium malate coexist in the berries, which contain also, upon the same authority, tannic and gallic acids, fixed oil, extractive, red coloring matter, and a little volatile oil. A medicinal wine has been prepared from the fruit. (*M. S. R.*, Feb. 9, 1867.) For a paper on the relative proportion of the constituents found in the husk and seed portion of the fruit by Frankforter and Martin see *A. J. P.*, 1904, 151.

Uses.—Sumach berries are astringent and refrigerant. A strong decoction, or the fluid-extract diluted, affords a very effective and pleasant gargle in *angina*, especially in combination with potassium chlorate. They are rarely used internally.

Dose, fifteen grains (1 Gm.).

ROSA GALICA. *U. S.* (Br.)

RED ROSE

(rō'sā gāl'ī-cā)

"The dried petals of *Rosa gallica* Linné (*Fam. Rosaceæ*), collected before expanding."

¹ Procter obtained, from the berries, malic acid by the following process. Pour boiling water on the ripe berries; macerate for twelve hours; strain, evaporate to one-fourth, and again strain; resume the evaporation, and continue it till the liquid assumes the consistence of thin syrup; then set it aside to crystallize. Wash the crystals of acid calcium malate with a little water, and recrystallize from a boiling solution. Dissolve the salt in hot water, and decompose it with a solution of lead acetate. Wash the precipitated lead malate, suspend it in water, and pass hydrogen sulphide through the liquid until the whole of the lead is separated. Lastly, filter, and evaporate to dryness in a porcelain vessel.

U. S. "The fresh and dried unexpanded petals of *Rosa gallica*, Linn. From cultivated plants." *Br.*

Rosæ Gallicæ Petals. *Br.*; Red-rose Petals; Flores Rosarum Rubrarum; Rose rouge ou Rose de Provins. *Fr. Cod.*; Roses rouges, *Fr.*; Sammtrose, Zuckerrose. Französische Rose, Essigrosenblätter, *G.*; Rosa rossa, *It.*; Rosa roja (Flore de), Rosa rubra, *Sp.*

Rosa gallica,¹ *L., Sp. Pl.* (1753) 492; Willd., *Sp. Plant.* ii. 1071; *B. & T.* 104.—This species is smaller than *R. centifolia*, *L.*, but resembles it in the character of its foliage. The stem is beset with short bristly prickles. The flowers are very large, with obovate widely spreading petals, which are of a rich crimson color, and less numerous than in the *R. centifolia*. In the centre is a crowd of yellow anthers on thread-like filaments, and as many villous styles bearing papillary stigmas. The fruit is oval, shining, and of a firm consistence. The red rose is a native of the south of Europe, and is cultivated in gardens throughout the United States.

The drug is officially described as "usually in small cones, consisting of numerous imbricated, roundish, retuse, deep purplish-red, yellowish-clawed petals, having a characteristic odor and a bitterish, slightly acidulous, and distinctly astringent taste." *U. S.* The petals should be gathered before the flower has blown, separated from their claws, dried in a warm sun or by the fire, and kept in a dry place. Their odor, which is less fragrant than that of *R. centifolia*, is improved by drying. They have a velvety appearance, a purplish-red color, and a pleasantly astringent and bitterish taste. Their constituents, according to Cartier, are tannin, gallic acid, coloring matter, a volatile oil, a fixed oil, albumen, soluble salts of potassium, insoluble salts of lime, silica, and ferric oxide. (*J. P. C.*, vii. 531.) According to Filhol, the astringency of red roses is ascribable less to tannic acid, of which they contain but a trace, than to quercitrin, which he obtained in notable proportion, and with which their color is probably connected. Rochleder found that in red roses the gallic acid is accompanied by quercitannic acid. They also contain much uncrystallizable sugar. (*Répert. de Pharm.*, Mai, 1863.) The sensible properties and medicinal virtues of the flowers are extracted by boiling water. Their coloring matter, according to Senier (*Y. B. P.*, 1877, p. 63), is an acid, which appears to form crystallizable salts with potassium and sodium, and amorphous ones with the heavy metals. Senier gives as the formula of the insoluble lead compound $Pb_2CaH_2O_{30}$. Their infusion is of a pale reddish color, becoming bright red on the addition of sulphuric acid. As their color is impaired by exposure to light and air, they should be kept in opaque well-closed bottles or canisters.

Uses.—Red rose is slightly astringent and tonic, and it was formerly thought to possess

¹ For other species of the genus see *Rosa*, PART II.

peculiar virtues. It is at present chiefly employed as affording an elegant vehicle for tonic and astringent medicines.

RUBUS. U. S.

RUBUS [Blackberry]

(rû'bûs)

"The dried bark of the rhizome of *Rubus villosus* Aiton, *Rubus nigrobaccus* Bailey, or of *Rubus cuneifolius* Pursh (Fam. *Rosaceæ*)." *U. S.*

Bramble, Finger Berry; Ecorce de Ronce noir, *Fr.*; Brambeeren, Brombeerrinde, *G.*

Of this extensive genus not less than thirty-five species are indigenous in the United States, where they are called by the various names of *raspberry*, *blackberry*, *dewberry*, *cloudberry*, etc. Most of them are shrubby or suffrutescent briars, with astringent roots and edible berries; some have annual stems without prickles. They are naturally divided into the *raspberries*, in which the edible fruit is composed of pulpy, one-seeded, coherent little drupes, separate from the dry receptacle, and the *blackberries*, in which the receptacle is juicy and coheres with the drupes to form the fruit. The *U. S. Pharmacopœia* (8th Rev.) recognizes as the source of rubus only three species, but it is probable that others contribute to the bark of the markets. In fact the *U. S. Pharmacopœia* of 1890 recognized officially *R. canadensis*, L., and *R. trivialis*, Michaux.

Rubus villosus, Ait., *Hort. Kew.* (1789) 210; Willd., *Sp. Plant.* ii. 1085.—The stem of the *blackberry* is somewhat shrubby, from three to seven feet high, branching, more or less furrowed and angular, and armed with strong prickles. The smaller branches and young shoots are herbaceous. The leaves are ternate or quinate; the leaflets ovate, acuminate, unequally and sharply serrate, and pubescent on both sides; the footstalks and midrib usually armed with short recurved prickles. The flowers are large, white, and in erect racemes, with a hairy, prickly stalk. The calyx is short, with acuminate segments. This plant is very common in thickets, half-cultivated fields, etc., extending from New England to Florida and west to Arkansas, fruiting in August and September. It is the original of the ordinary form of the cultivated blackberry.

Rubus nigrobaccus, Bailey (*R. villosus*, Gray; not Aiton), *High Bush Blackberry*, is a stout bush, reaching the height of 8 or 9 feet, with erect, recurved, glandular-pubescent stems much branched and armed with stout recurved prickles. Its 3 to 5 foliolate leaves have ovate or ovate-oblong leaflets, which are acute, coarsely serrate, and pubescent beneath. The racemosed paniculate flowers are furnished with

small bracts and have white obovate petals much longer than the sepals. The fruit is usually black and pulpy though a variety with small white fruit is said to occur. This plant is common in the Eastern United States from New England to Florida.

Rubus cuneifolius, Pursh. *Sand Blackberry* is a shrubby plant, rarely reaching the height of over three feet, much branched, with stout straight or recurved prickles, and dense whitish pubescence on the lower surfaces of the leaves and upon the young shoots. The leaves are furnished with linear stipules, are 3 to 5 foliolate, long petioled with obovate or oval lateral and cuneate terminal leaflets, which are obtuse, and dentate above the middle. The peduncles are furnished with two to five pinkish-white flowers, which yield a large brownish-black fruit. This blackberry inhabits almost the whole of the Eastern United States, affecting sandy soils.

The blackberry root is branching, cylindrical, of various dimensions, from nearly an inch in thickness down to the size of a straw, ligneous, and covered with a thin bark, which is externally of a light brownish or reddish-brown color, and in the dried root is wrinkled longitudinally. The dewberry root is usually smaller, without the longitudinal wrinkles, but with transverse fissures through the epidermis, and of a dark ash color, without any reddish tinge. Both are inodorous. The bark is "in elongated, tough, flexible quills, from 3 to 6 Mm. in diameter, or in similar bands, the bark 1 to 2 Mm. thick; outer surface deep red-brown or dark gray-brown, occasionally blackish-brown, smoothish or somewhat scaly; inner surface yellow or pale brownish, strongly and coarsely long straight-striate; fracture tough-fibrous; readily splitting; inodorous; taste strongly astringent and bitterish." *U. S.* Its virtues are extracted by boiling water and by diluted alcohol, and depend chiefly upon tannin, which is an abundant constituent.¹ The woody part of the roots is inert.

Uses.—Dewberry and blackberry roots have long been a favorite domestic astringent remedy in *diarrhœas*. Given in decoction, they are usually acceptable to the stomach, without being offensive to the taste. The decoction may be prepared by boiling an ounce of the smaller roots, or of the bark of the larger, in a pint and a half of water down to a pint, of which from one to two fluidounces (30 to 60 Cc.) may be given to an adult three or four times, or more frequently, during the twenty-four hours. The fluidextract is an excellent preparation; dose, thirty to sixty minims (1.8 to 3.75 Cc.).

¹ **Aromatic Syrup of Blackberry.**—Take of Blackberry Root 2 oz. troy; Cinnamon, Cloves, each, 90 grains; Mace 60 gr.; Sugar 30 oz. troy. Reduce the root and spices to a powder which will pass through a sieve of 50 meshes to the square inch, moisten this with two fluidounces of alcohol, put into a percolator and displace with water until 17 fluidounces have passed, and dissolve the sugar in the filtrate. A fluidounce is equivalent to 30 grains of the root. (*A. J. P.*, Nov. 1859, p. 552.)

Dose, from twenty to forty grains (1.3 to 2.6 Gm.).

Off. Prep.—Fluidextractum Rubi, *U. S.*; Syrupus Rubi, *U. S.* (from fluidextract).

SABAL. U. S.

SABAL [Saw Palmetto]

(sā'bal)

"The partially dried ripe fruit of *Serenoa serrulata* (Roemer and Shultes) Hooker filius (Fam. *Palmæ*)." *U. S.*

The *Saw palmetto* flourishes on the Atlantic coast from South Carolina to Florida, where it forms the so-called "palmetto scrub." Its stem, which is from 6 to 10 feet high, has a crown of large leaves, long petioled, with a circular fan-shaped leaf blade split at the edge into from 15 to 30 divisions, which are slightly cleft at their apices. The fruit is a one-sided blackish-brown drupe, from half an inch to one inch long; ovoid-oblong in shape, with a somewhat wrinkled exterior, and a sweetish, not agreeable taste. It occurs in a large panicle which in some cases may weigh as much as nine pounds.

Properties.—Sabal is officially described as follows: "Irregularly spherical to oblong-ovoid; 10 to 25 Mm. long, 10 to 15 Mm. in diameter; externally blackish-brown, shrivelled, somewhat oily; epicarp thin; sarcocarp about 1 Mm. thick, greenish-yellow, soft-spongy; endocarp thin, friable; seed hard, chocolate-brown; odor aromatic; taste sweetish, acid, and oily." *U. S.* In it Coblenz (*Proc. New Jersey Pharm. Assoc.*, 1895, 45) believes that he found, besides a volatile oil an alkaloid. In the studies of Sherman and Briggs (*Ph. Archiv.*, vol. 2) no alkaloid could be detected. Sieker (*Ph. Rev.*, 1897, 113) examined the fixed oil: the sp. gr. was 0.9138, and it was soluble in alcohol, ether, and petroleum benzin. By pressure the fruit yields about 1½ per cent. of a brownish-yellow to dark red oil, soluble in alcohol, ether, chloroform and benzene, and partly soluble in dilute solution of potassium hydroxide. It contains, according to Sherman and Briggs (*Ph. Archiv.*, 1899, 101; see also *Ph. Rev.*, 1900, 217) about 63 per cent. of free acids, and 37 per cent. of ethyl esters of these acids. The oil obtained exclusively from the nut was thick and of a greenish color, without fruity odor. It was a glyceride of fatty acids.

Uses.—The oil of saw palmetto is probably eliminated through the kidneys unchanged, although we know of no actual experiments to prove this, and appears to exert a stimulant alterative action upon the mucous membrane of the genito-urinary tract, similar to that of other alterative diuretics. Saw palmetto is milder and less stimulant than is cubeb or copaiba, or even the oil of sandal-wood. Like these drugs it also has the power of affecting the re-

spiratory mucous membrane, so that it has been used not only in *chronic* and *sub-acute* cystitis, but also in *chronic bronchitis*, *laryngitis*, and the catarrhs which accompany *asthma*, *phthisis*, and other more serious diseases of the lungs. It has been affirmed that saw palmetto is capable of increasing the nutrition of the testicles and of the mammae in functional atony of these organs, but this is very doubtful. It has been especially recommended in cases of *enlarged prostate* of old men; it is not probable that it has a direct influence upon the prostatic gland itself but there is much clinical testimony as to its value and it probably acts by reducing the catarrhal irritation and the relaxed condition of the mucous membrane of the bladder and urethra, which are almost universally present in prostatic hypertrophy. Dose of the fluidextract,¹ ten to twenty-five minims (0.6 to 1.6 Cc.). It is not official but is probably the best form of using the drug, the oil not being on the market.

Dose, fifteen grains (1 Gm.).

SABINA. U. S.

SAVIN

(sā-bi'nā)

"The tops of *Juniperus Sabina* Linné (Fam. *Conifera*)." *U. S.*

Sabinæ Cacumina; Summitates (Herba) Sabinæ, Savine Tops; Sabine, *Fr. Cod.*; Sevenbaum, Sadebaumsitzen, Sevenkraut, *G.*; Sabina, *It.*, *Sp.*

Juniperus Sabina, L., *Sp. Pl.* (1753) 1039; Willd., *Sp. Plant.* iv. 852; B. & T. 254.—This is an evergreen shrub from three to fifteen feet high, with numerous erect, pliant branches, much subdivided. The bark of the young branches is light green, that of the trunk rough and reddish brown. The leaves, which completely invest the younger branches, are numerous, small, erect, firm, smooth, pointed, dark green, glandular in the middle, opposite, and imbricated in four rows. The flowers are male and female on different trees. The fruit is a blackish-purple berry of an ovoid shape, marked with tubercles and the remains of the calyx and petals, and containing three seeds. The savin is a native of the south of Europe and the Levant, and grows wild in the neighborhood of the northwestern lakes of the United States.

The ends of the branches, and the leaves by which they are invested, are collected for

¹ *Fluidextract of Sabal*—Sieker proposed the following formula for this fluidextract: Moisten 1000 Gm. of saw palmetto, in No. 40 powder, with 300 Cc. of alcohol, and proceed to percolate with alcohol in the usual manner, reserving the first 850 Cc. of percolate, distilling the alcohol from the exhaust percolate, dissolving the extract in the reserved portion, and adjusting the volume of the fluidextract to 1000 Cc. with alcohol. The clear fluidextract so obtained has the yellowish brown color, odor and taste of the commercial type, a sp. gr. of 0.8807 at 25° C., and yielded 12.98 per cent. of oil and 13.6 per cent. of extract. (*Ph. Rund.*, Oct. 1895, 236.)

medicinal use in the spring. When dried they are very much faded in color. They are officially described as "short, thin, subquadrangular branchlets bearing leaves which are rather dark green, in four rows, opposite, scale-like, ovate-lanceolate, more or less acute, appressed, imbricated, having on the back a shallow groove containing an oblong or roundish gland; odor peculiar, terebinthinate; taste disagreeable, resinous and bitter." *U. S.* They have a strong, heavy, disagreeable odor, and a bitter, acrid taste. These properties, which are less striking in the dried than in the recent leaves, are owing to a volatile oil. (See *Oleum Sabinae*.) The leaves impart their virtues to alcohol and to water. C. H. Needles found in them volatile oil, gum, tannic or gallic acid, resin, chlorophyll, fixed oil, bitter extractive, lime, and salts of potassium. (*A. J. P.*, xiii. 15.)

In America the tops of *Juniperus virginiana*, or common red cedar, are sometimes substituted in commerce for savin, which they resemble closely, but from which they can be distinguished by some of their leaves being ternate, by having stone cells in the mesophyll, and by differing in odor and taste. In Europe savin is said to be adulterated with the tops of *J. phœnicea*, which contain volatile oil similar to that of *J. communis*. Such substitution is to be detected by the fact that in *J. phœnicea* the leaves are imbricated in spirals of five, and that in the mesophyll there are large stone cells which do not appear in the official species.

Uses.—Savin is highly irritant, and is supposed to have a special direction to the uterus. It has been much used in *amenorrhœa* and *atonic menorrhagia*, and occasionally as a remedy for worms. Chapman strongly recommended it in *chronic rheumatism*, and it is employed in Germany, both internally and externally, in *chronic gout*. In overdoses it may produce dangerous gastro-intestinal inflammation, and it should therefore be used with caution. In no case should it be employed when much general or local excitement exists. In pregnancy it should always be given with great caution. The dose of the fluidextract is from five to ten minims (0.3 to 0.6 Cc.); of the oil, three minims (0.2 Cc.). As an external irritant, savin is useful, in the form of cerate, for maintaining a discharge from blistered surfaces; but as in this country savin ointment is often feeble, either from the age of the drug or from the substitution of red cedar, it has fallen into disrepute. In powder or infusion, savin is used in Europe as an application to *warts*, *indolent* or *gangrenous ulcers*, *psora*, and *tinea capitis*, and the expressed juice of the fresh leaves, diluted with water, is sometimes used for similar purposes. Powdered savin should not be used after it has lost the green color, characteristic of the fresh drug.

Dose, five to ten grains (0.32 to 0.65 Gm.).

Off. Prep.—Fluidextractum Sabinae, *U. S.*

SACCHARUM. U. S. (Br.)

SUGAR [Cane Sugar]

(sắc'chạ-rũm)

"The refined sugar obtained from *Saccharum officinarum* Linné, and from various species or varieties of *Sorghum* (Fam. *Gramineæ*); also from one or more varieties of *Beta vulgaris* Linné (Fam. *Chenopodiaceæ*)." *U. S.* "A crystallized sugar, $C_{12}H_{22}O_{11}$, obtained from the juice of the sugar-cane." *Br.*

Saccharum Purificatum, Br.; Refined Sugar, Cane Sugar, Sucrose; Sucre de Canne, *Fr. Cod.*; Sucre, Sucre pur, Sucre en Pains, *Fr.*; Saccharum, *P. G.*; Weisses Zucker, Zucker, Rohrzucker, *G.*; Zucchero, *It.*; Azucar, Azucar refinado, *Sp.*

Saccharum officinarum, L., *Sp. Pl.* (1753) 54; Willd., *Sp. Plant.* i. 321; *Philos. Trans.* lxi. 207.—The sugar cane is an herbaceous plant, possessing a jointed, succulent rhizome, from which arise several shining, jointed, solid stems, from an inch to two inches in diameter, from six to twelve feet high, and containing a white and juicy pith. The color of the stem is yellow, greenish yellow, purple, or striped. The joints are about three inches apart, and give origin to the leaves, which embrace the stem at their base, are three or four feet long and about an inch wide, flat, acuminate, longitudinally striated, furnished with a white midrib, glabrous, finely dentate, and of a green color inclining to yellow. The flowers are pinkish, surrounded by a long silky down, and disposed in a large, terminal, nearly pyramidal panicle, composed of subdivided spikes, and two or three feet in length. The plant has a general resemblance to the Indian corn. Four varieties are mentioned: 1, the common, with a yellow stem; 2, the purple, with a purple stem and richer juice; 3, the gigantic, with a very large light-colored stem; and 4, the *Otaheitan*, which was introduced into the West Indies from the island of Tahiti (Otaheite) by Bougainville and Bligh, and is distinguished by its greater height, the longer intervals between its joints, and the greater length of the hairs which surround the flowers.

The sugar cane is cultivated by cuttings, which are planted in rows, and which, by giving rise to successive shoots, furnish five or six crops before the plants require to be removed. At the end of a year or more the plant flowers, but before this takes place the canes are richest in sugar and are cut down. The quantity of sugar which they yield is variable. According to Avequin of New Orleans, the proportion of cane sugar in the recent stalk is about 10 per cent.; of uncrystallizable sugar from $3\frac{1}{2}$ to 4 per cent. Cane juice is said to contain 17 per cent. of crystallizable sugar, though not more than 13 per cent. is extracted in practice.

Among the saccharine principles distinguished by the chemist are cane sugar, or sugar

properly so called, derived from the sugar cane, the beet, and the sugar maple, and having the formula $C_{12}H_{22}O_{11}$; lactose or milk sugar, and maltose, a product of the action of diastase upon cereals, possessing the same formula; glucose, including dextrose or grape sugar, levulose or fruit sugar, the mixture of the two produced by the hydrolysis of cane sugar and known as invert sugar, and that resulting from the change of starch and starch-containing cereals; arabinose, from gum arabic, agreeing with glucose in the formula $C_6H_{12}O_6$; mannite (mannitol), and duleite (duleitol), which are alcohol-like compounds closely related to the true sugars. Quereite, pinite, and inosite were formerly regarded as either pentatomic alcohols or glucoses, but are now considered to be hexahydro derivatives of a pentatomic phenol as yet unprepared. *Glucose*, or *grape sugar*, is conveniently obtained by spreading crystalline honey on porous tiles, dissolving what remains on their surface in alcohol, and crystallizing. The product is about one-fourth of the weight of the honey. It is also prepared from starch by the action of very weak sulphuric acid and this industry has assumed enormous proportions in this country in the last decade. In the report of the 1890 census, the capacity of the factories in the United States was estimated at 43,000 bushels of corn per day. In 1905 the annual production of glucose and grape sugar was from 250,000 to 300,000 tons.

The term glucose is applied to the syrupy product of this process, while the name grape sugar is limited to the solid substance from the same source. The process, in outline, is as follows: The corn is first soaked for two or three days in warm water, and is then ground on specially prepared stones with a stream of water. The meal is next passed into a trough, the bottom of which is made of fine bolting cloth. Here the starch is washed through and led to large tanks, where it is allowed to settle. It is next beaten up with sodium hydroxide, to separate the gluten, and the starch is again allowed to settle in long shallow troughs. The starch, washed from all adhering alkali, is next beaten up with water into a cream, and conducted into the converting tubs. These tubs are supplied with coils of copper steam piping, and are made of wood. Here the starch cream is treated with diluted sulphuric acid, and steam is allowed to bubble up through the mixture from small holes in the copper pipes. This process of conversion, which is called "open conversion," is completed in about two hours. Another method is called "close conversion." The substances are enclosed in stout copper cylinders and subjected to the action of superheated steam. This process occupies about fifteen minutes. After conversion, the acid is neutralized by marble dust and animal charcoal. Since the calcium sulphate which is formed in this operation is slightly soluble, barium carbonate has been used instead of marble dust, but its use has

not become general. After neutralization, the liquid is filtered through cloth and animal charcoal, and is then conveyed to the vacuum pan. When glucose syrup alone is desired, the process of conversion is stopped when the starch has disappeared, so that the syrup contains both glucose and dextrin, while when solid grape sugar is desired, the conversion is carried further to the change of dextrin into dextrose. Glucose can be obtained as a hydrate in small and laminated crystals from aqueous solution, and anhydrous in hard crystalline masses either from alcoholic solution or, by the process used by Arno Behr (*A. J. P.*, Aug. 1882, p. 397), from very concentrated aqueous solution. It is less sweet than cane sugar. It is also less soluble in water, and much more soluble in alcohol. It has the sp. gr. 1.54 to 1.57 when anhydrous. Strong mineral acids hardly act on grape sugar, but destroy cane sugar with facility. On the other hand, grape sugar is destroyed by alkalis, with which cane sugar forms definite compounds. Dissolved in water and subjected to prolonged ebullition, grape sugar undergoes very little alteration. Its solution rotates the plane of polarization of polarized light to the right, and is capable of undergoing the vinous fermentation directly, without passing through any intermediate state. It is characterized also, in boiling solution, by reducing alkaline copper tartrate, and by becoming brown by the action of the alkalis.

The name of *glucosides* has been given to certain organic substances which are resolvable, by the presence of acids, or other slight chemical influence, into glucose and some other proximate principle, as in the instance of one variety of tannic acid, which is resolved into glucose and gallic acid. E. Fischer announced (*Ber. d. Chem. Ges.*, 1893, 2400) the discovery of a general method for the formation of glucosides. He finds that, if a glucose be dissolved in an alcohol and gaseous hydrochloric acid be passed into the solution to saturation, the two compounds unite with the elimination of water to form a glucoside or ester of the two. He has found this reaction to extend to methyl, ethyl, propyl, isopropyl, amyl, allyl, and benzyl alcohols, to ethyleneglycol, and glycerin, and even to the oxyacids or alcohol acids like lactic acid. He has tested it for mannose, galactose, dextrose, fructose, gluco-heptose, arabinose, xylose, and rhamnose. *Fruit sugar*, or *levulose*, is an isomeric form of glucose, found in honey and in the juice of fruits; an uncrystallizable mixture of dextrose and levulose (both varieties of glucose) is generated from cane sugar by solution in water or weak acids, and long boiling. Hence it is present in molasses. An aqueous solution of this sugar, like grape sugar, is susceptible of the vinous fermentation without an intermediate change. In consequence of its effect on polarized light, it has been named by the French chemists *invert sugar* (*sucro interverti*), its rotatory power being the reverse

of that of the sugar from which it is produced. A solution of *cane sugar*, like that of grape sugar, has a rotating power to the right. When it ferments, it is first changed into uncrystallizable sugar, according to the reaction:

and, as the change proceeds, the rotating power to the right of the cane sugar gradually lessens and disappears, and is replaced by the rotating power to the left of the uncrystallizable sugar formed.

Classification of the Carbohydrates.—The group of the carbohydrates has been studied by Emil Fischer, who has not only made numerous syntheses in this group, but has greatly widened our knowledge of the relations of the several sugars, making necessary a more comprehensive classification. Thus, while no sugars are found in nature containing less than six atoms of carbon, synthetic compounds are formed belonging in the first or monosaccharide class which contain three, four, and five atoms of carbon, as well as others containing seven, eight, and nine atoms of carbon. The classification given below, is based on that of Tollens.

I. MONOSACCHARIDES.

Trioses.—Glycerose, $C_3H_6O_3$ (prepared from glycerin by oxidation).

Tetroses.—Erythrose, $C_4H_8O_4$ (prepared from erythrite by oxidation).

Pentoses.—Arabinose, $C_5H_{10}O_5$ (prepared by the action of dilute sulphuric acid upon lævo-rotatory gum arabic; xylose, $C_5H_{10}O_5$ (prepared by boiling beech wood and jute with dilute acids); rhamnose or isodulcitol, $C_6H_{12}O_6$ (CH₃)₆, methyl pentose (obtained in the decomposition of glucosides like quercitrin).

Hexoses.—Glucose or dextrose, $C_6H_{12}O_6$; fructose or levulose, $C_6H_{12}O_6$; mannose, $C_6H_{12}O_6$ (obtained by the careful oxidation of mannite); galactose, $C_6H_{12}O_6$.

Heptoses. $C_7H_{14}O_7$. Manno-heptose (obtained artificially from the corresponding mannose); gluco-heptose (obtained artificially from the corresponding glucose).

Octoses. $C_8H_{16}O_8$. Manno-octose (prepared from the corresponding mannose); gluco-octose (prepared from the corresponding glucose).

Nonoses. $C_9H_{18}O_9$. Manno-nonose (prepared from the corresponding mannose); gluco-nonose (prepared from the corresponding glucose).

II. DISACCHARIDES AND TRISACCHARIDES.

Tribioses and tetrabioses are as yet unknown.

Pentabioses.—Arabinon, $C_{10}H_{18}O_9$ (has been prepared by the moderated action of dilute sulphuric acid upon arabic acid).

Hexabioses.—Cane sugar, $C_{12}H_{22}O_{11}$; milk sugar, $C_{12}H_{22}O_{11}$; maltose, $C_{12}H_{22}O_{11}$; isomaltose, $C_{12}H_{22}O_{11}$; trehalose, $C_{12}H_{22}O_{11}$.

Hexatrioses.—Meletriase or raffinose, $C_{18}H_{32}O_{16}$; melezitose, $C_{18}H_{32}O_{16}$.

III. POLYSACCHARIDES.

(a) **Crystallizable polysaccharides.**—Gentianose, lactosin.

(b) **Uncrystallizable polysaccharides.** Starches, liehnin, inulin, glycogen, dextrin, natural gums, pectin substances, cellulose, lignin, tunicin.

Cane sugar is manufactured extensively on the continent of Europe from the beet, and this industry is now growing in this country, especially in California. It is also largely produced in Canada and the northern parts of the United States from the sap of the sugar maple (*Acer saccharinum*). Cane sugar may be obtained from cornstalks, and from the *Chinese sugar cane*, or *Sorghum saccharatum*, which latter source for a time assumed some importance in Kansas and the Northwest. In India, sugar is made from the sap of different species of palm. Crude *palm sugar* is called *jaggery*. Next in rank to the sugar beet as a source of cane sugar is the sugar cane, which is extensively cultivated in Africa, the East and West Indies (especially Cuba), Brazil, and some of our Southern States, particularly Louisiana.

Preparation and Purification.—The canes, when ripe, are cut down close to the earth, topped, and stripped of their leaves, and then crushed between a series of horizontally placed iron rollers in a mill, or they are cut in thin transverse slices and the juice extracted by diffusion with warm water. The juice, constituting 90 per cent. of the cane, though much less is actually obtained, is of a pale greenish color, sweet taste, and balsamic odor, and has a sp. gr. varying from 1.033 to 1.106. As it runs out it is received in suitable vessels, and, being quickly removed, is immediately mixed with lime, in the form of milk of lime, in the proportion of about 1 part of the earth to 800 parts of the juice, and heated in a boiler to 140° F. The exact proportion of the lime cannot be determined, as the juice varies in quality in different seasons; but the manufacturer should aim at leaving the juice still slightly acid. The gluten and albumen rise to the top, and form a thick scum, from underneath which the liquid is drawn off by a cock into a copper boiler, where it is concentrated by heat, the scum being carefully skimmed off as it forms. When sufficiently concentrated, the juice is transferred to shallow vessels called coolers, from which, when it assumes a granular aspect, it is drawn off into wooden vessels with perforated bottoms, the holes in which are temporarily plugged. At the end of twenty-four hours the liquid is strongly agitated with wooden stirrers, in order to accelerate the granulation of the sugar, which is completed in six hours. The stoppers are now removed, and the syrup is allowed to drain off from the sugar, which in this state is granular, of a yellowish color, and moist. The syrup, by a new evaporation, furnishes an additional portion of sugar, and the liquid which finally re-

mains, incapable of yielding more sugar with advantage, is called *molasses*. Sugar produced in this way is called "open pan" sugar. It is now almost completely displaced by "vacuum pan" sugar.

In the production of raw sugars by the vacuum pan process, the juice, after "defecation" with lime and removal of excess of lime by carbonic acid gas, is run through large filters of bone black, and then into a vacuum pan for concentration. The vacuum pan is a large evaporating pan, closed above by a dome-like top, which connects with an exhausting steam pump, so that the liquid can be concentrated under very reduced pressure. The heat is supplied by coils of steam pipes which run through the interior of the pan. The saccharine juice is evaporated in this until it begins to crystallize, and even after this fresh portions are added, so that the crystals already formed grow by accretion of fresh material. After the crystallization is complete, the warm mixture of crystals and syrup is run into "centrifugals," to which a rapid motion of revolution is given, and the crystals so drained and dried.

There is no doubt that a large proportion of the sugar is lost in the ordinary process of manufacture. Melsens of Brussels, proposed a process, which consists in the use of calcium bisulphite. This salt is alleged to act as an antiseptic, preventing the operation of any ferment; as an absorber of oxygen, opposing the action of that gas on the juice; as a clarifier, rendering insoluble at 100° C. (212° F.) all coagulable matters; as a bleacher of pre-existing coloring matters, and a preventive of the formation of new ones; and, lastly, as a substance furnishing a base to neutralize hurtful acids, which unite with the lime, displacing the weaker sulphurous acid. This process is now largely used, and calcium bisulphite is used in British Guiana and other sugar-producing countries in immense quantities. Emil Pfeiffer proposed another refining process, which consists in the use of acid calcium phosphate, an agent previously recommended by Brande. Reynoso considered alumina the best defecating agent, having succeeded by means of it in throwing down almost all impurities most hurtful. He adds the acid aluminum phosphate to the cane juice, and decomposes this with lime, by which the calcium phosphate is produced and alumina separated, and all these, with some lime in excess, cause the elimination of coloring and nitrogenous matters, so that there remain in the liquid only some of the salts which normally accompany the sugar in the juice. (*J. P. C.*, 4e sér., ii. 232.)

The refining of brown sugar forms a distinct branch of business, and the methods pursued have undergone many improvements. The sugar was first "melted"—that is, dissolved in hot water—and then clarified by heating it with bullock's blood. The clarified syrup was then strained through cloth filters, whereby it

was rendered limpid. The clear straw colored syrup from the bag filters was then run into the char filters,—that is, large filters filled with freshly ignited bone black. The syrup after filtration goes to the vacuum pans. This great step in advance was taken by Philip Taylor and Howard. The former introduced the improvement of heating the syrup with great rapidity by means of steam made to pass through a series of tubes traversing the boiler, and the latter devised the plan of causing the syrup to boil under a diminished pressure, created by a suction pump, set in motion by a steam engine, while it was heated by steam circulating round the boiler. In this way the syrup was made to boil at a lower temperature, and with a diminished contact of the air, and the loss of cane sugar by change into that which was uncrystallizable was in great measure avoided. Two, three, or even four vacuum pans may be coupled together, so as to economize fuel, and the vapors arising from one made to heat the next, in which a more perfect vacuum exists, allowing of evaporation at still lower temperatures. Such a combination is called a double, triple, or quadruple effect apparatus.

After the syrup is sufficiently concentrated by any one of these methods, it is transferred to coolers, where it is agitated to cause it to granulate. In this state it is poured into unglazed earthenware moulds of a conical shape, with a hole in the apex, which is stopped with a paper plug. The moulds are placed, with the apex downward, above stoneware pots, intended to receive the uncrystallizable syrup. When the mass has completely congealed, the moulds are unstopped, to allow the colored syrup to drain off. To separate the remains of this syrup, the operation called *claying* is performed. This consists in removing from the base of the loaf a layer of sugar about an inch thick, and replacing it with pure sugar in powder, which is covered with a mixture of pipe clay and water of about the consistence of cream. The water gradually leaves the clay, dissolves the pure sugar, and percolates the mass as a pure syrup, removing in its progress the colored syrup. Sometimes the purification is performed without the use of clay, by allowing a saturated solution of pure sugar to percolate the loaf. When all the colored syrup is removed, the loaf is taken out of the mould and placed in stoves to dry. It now constitutes *white* or *purified sugar*. The syrup which drains from the loaves contains a considerable quantity of cane sugar, and is used in subsequent operations. This process of forming *loaf sugar* by claying and displacing colored syrup by white syrup is now almost entirely replaced by the process already described under raw sugars of crystallizing in the vacuum pan and draining with a centrifugal. The syrups of lowest quality are employed in forming inferior white sugar, from which a syrup finally drains containing so

little cane sugar as not to repay the expense of extracting it. This constitutes *sugar-house molasses*. Good brown sugar, in the process of refining, yields about 70 per cent. of white sugar. The application of animal charcoal to the refining of sugar is now very extensive.

Commercial History.—Cane sugar was known to the ancients. It was originally obtained from India, where it was extracted from the sugar cane. About the period of the Crusades, the Venetians brought it to Europe; but at that time it was so scarce and costly as to be used exclusively as a medicine. Upon the discovery of the Cape of Good Hope and the maritime route to the East Indies, the commerce in sugar passed into the hands of the Portuguese. Subsequently the cultivation of the cane extended to Arabia, Egypt, Sicily, Spain, and the Canaries, and finally, upon the discovery of the New World, to America, where it was pursued with the greatest success, and continues to be so. In America it was produced most abundantly in the West Indies, which supplied also a part of the consumption of Europe. The Cuban production, which at one time amounted to over 750,000 tons, has lessened greatly in recent years because of the disturbed condition of the island. The production in Louisiana, once large, diminished under the competition of the foreign beet sugar production, but in recent years, under the stimulus of a bounty, it has increased, and now amounts to about 300,000 tons per year. However, the American production from the sugar beet has developed rapidly in the last decade, advancing from 10,000 tons in 1892 to 247,563 tons in 1903 and 170,135 tons in 1904. This production centres in California, Nebraska, Utah, and Michigan, but individual factories have been erected in New Mexico, Arizona, and as far east as New York State.

The following figures show the production of sugar throughout the world from the two main sources, the sugar cane and the sugar beet.

Beet sugar, 1903-4, 5,953,700 tons; 1904-5, 4,978,300 tons; 1905-6, 7,088,800 tons. Cane sugar, 1903-4, 4,244,200 tons; 1904-5, 4,627,800 tons; 1905-6, 4,947,500 tons. Total amount of sugars, 1903-4, 10,197,900 tons; 1904-5, 9,606,100 tons; 1905-6, 12,036,300 tons.

The importations of raw sugars into the United States for 1904 were 1,652,064 tons, valued at \$71,915,750 almost entirely from the sugar cane.

Properties.—Sugar, in a pure state, is a solid of a peculiar grateful taste, permanent in the air, phosphorescent by friction, and of the sp. gr. 1.6. It forms "white, dry, hard, distinctly crystalline granules, odorless, and having a purely sweet taste. Permanent in the air. The aqueous solution, saturated at 25° C. (77° F.), has a specific gravity of about 1.340, is miscible with water in all proportions, should be colorless, and is dextrogyrate. Soluble in 0.46 part of water, and in 137.2 parts of alcohol at 25° C. (77° F.); in 0.2

part of boiling water, and in 28 parts of boiling alcohol; also soluble in 80 parts of boiling absolute alcohol, but insoluble in ether, chloroform, or carbon disulphide. The aqueous or alcoholic solution of Sugar is neutral to litmus paper." *U. S.* "Colorless and inodorous separate crystals. Readily and completely soluble in half its weight of water, forming a clear bright syrup. When the syrup is heated to about 180° F. (82.2° C.) with solution of *potassio-cupric tartrate* or with solution of *copper sulphate* and excess of solution of *potassium hydroxide*, there should not result more than a trace of a red or yellowish precipitate (absence of glucose). Refined sugar should yield no reaction with the tests for calcium, chlorides, and sulphates." *Br.* Its solution, when thick and strong, is called *syrup*, and when alcohol is mixed with it, the sugar is gradually deposited in crystals. An aqueous solution of sugar, kept in a warm place, has the property of corroding iron, partially immersed in it, just above the line where the surface of the liquid touches the metal, and the solution itself becomes impregnated with ferrous oxide, and of a deep red-brown color. A similar effect is produced on lead, but zinc and copper are but slightly acted on. (J. H. Gladstone, *Annals of Pharmacy*, iii. 208.) A solution of sugar possesses the property also of dissolving a large quantity of calcium hydroxide, forming a compound called *calcium saccharate*. When a concentrated syrup is gently heated, and spirit added to it, the liquid, on cooling, forms white semi-transparent crystals of hydrated sugar, having the shape of oblique four-sided prisms, and called *rock candy*. When heated to 185° C. (365° F.), it melts into a viscid, colorless liquid, which on being suddenly cooled forms a transparent mass, called *barley sugar*. At a higher temperature (between 204.4° and 215.5° C. (400° and 420° F.) it loses two molecules of water, and is converted into a black porous mass, having a high lustre, called *caramel*.¹ At a still higher temperature it yields combustible gases, carbon dioxide, empyreumatic oil, and acetic acid, and there remains one-fourth of its weight of charcoal, which burns without residue. Sugar renders the fixed and volatile oils to a certain extent miscible with water, and forms with them an imperfect combination; such mixtures are called *oleo-saccharures*. When in solution, it is not precipitated by lead subacetate, a negative property which distinguishes it from most other organic principles.

¹ A coloring substance called *caramel brown* or *sucré couleur* is now largely manufactured from sugar by decomposing it by means of heat carefully applied. It is in the form of a stiff paste, in which it is used for coloring leather, or of a syrup, for coloring liquids. *Sucré couleur* is now extensively manufactured abroad for coloring rum and spirituous liquors, beer, and wine. It is made exclusively from starch sugar, either by a simple process of heating, or by heating with addition of sodium carbonate or ammonium carbonate. (For details, see *Starch, Glucose, Starch Sugar*, etc., by Wagner, translated by Frankel, H. C. Baird & Co., Phila.)

Tests.—"Both the aqueous and the alcoholic solution of Sugar should be clear and transparent. When kept in large, well-closed and completely filled bottles, the solutions should not deposit a sediment on prolonged standing (absence of *insoluble salts, ultramarine, Prussian blue*, etc.). If 1 Gm. of Sugar be dissolved in 10 Cc. of boiling water, the solution mixed with 4 or 5 drops of silver nitrate T.S., then about 2 Cc. of ammonia water added, and the liquid quickly brought to the boiling point, not more than a slight coloration, and no black precipitate, should appear in the liquid after standing at rest for five minutes (absence of *glucose*, and of more than a slight amount of *inverted sugar*)."
U. S. Sugar is sometimes adulterated with crystallized glucose, and it is a common practice among many sugar refiners to "blue" sugar to conceal the yellowish tint due to insufficient refining; ultramarine was formerly largely used but on account of the syrups made from sugar "blued" by ultramarine developing a disagreeable odor, refiners now use Prussian blue and some of the methylene blue dyes. See the official test above. Cane sugar may be distinguished from grape sugar by Trommer's test, which consists in the use of copper sulphate and potassium hydroxide. If a solution of cane sugar be mixed with a solution of copper sulphate, and potassium hydroxide be added in excess, a deep blue liquid is obtained, which on being heated lets fall, after a time, a little red powder. A solution of grape sugar, similarly treated, yields, by heat, a copious greenish precipitate which rapidly changes to scarlet and eventually to dark red. Böttger finds that, when a liquid containing grape sugar is boiled with sodium carbonate and some basic bismuth nitrate, a gray coloration or blackening of reduced bismuth is produced. Cane sugar, similarly treated, has no effect on the test. Donaldson's test for sugar in the *animal fluids* is formed of 5 parts of sodium carbonate, 5 of potassium hydroxide, 6 of potassium bitartrate, 4 of copper sulphate, and 32 of distilled water. A few drops of this solution being added to an animal fluid, and the mixture heated over a spirit-lamp, a yellowish-green color is developed, if sugar be present. J. Horsley's test for sugar in diabetic urine is an alkaline solution of potassium chromate, a few drops of which, boiled with the urine, will make it assume a deep sap-green color. M. J. Nicklé recommends carbon tetrachloride as a test for distinguishing glucose from cane sugar. This liquid mixed with cane sugar in a glass tube, kept for some time near 100° C. (212° F.), causes a darkening of the sugar, gradually increasing until it becomes black. Glucose undergoes no such change. (*J. P. C.*, 4e sér., iii. 119.)

Action of Acids and Alkalies.—The mineral acids act differently on cane sugar according as they are concentrated or dilute. Strong nitric acid, with the assistance of heat, converts it into oxalic acid. (See *Oxalic Acid*.)

The same acid, when weak, converts it into *saccharic acid*, confounded by Scheele with malic acid. Concentrated sulphuric acid chars it. Diluted hydrochloric acid, when boiled with cane sugar, converts it into a solid, brown, gelatinous mass. Weak sulphuric acid, by a prolonged action at a high temperature, converts cane sugar, first into uncrystallizable sugar, afterwards into grape sugar, and finally into *ulmin* and *ulmic acid*. Vegetable acids are supposed to act in a similar way. Maumené found that cane sugar undergoes the change into uncrystallizable sugar when kept for a long time in aqueous solution, as well as when heated with acids. When the boiling with acids is prolonged for several days in open vessels, oxygen is absorbed, and, besides ulmin and ulmic acid, formic acid is generated. Soubeiran admits the change of the uncrystallizable into grape sugar, but attributes it to a molecular transformation of the sugar, independently of the action of the acid, as, according to his observation, the conversion takes place only after rest. In confirmation of his views, this chemist states that he found the same changes to be produced by boiling sugar with water alone. Not only does cane sugar change into the uncrystallizable variety when boiled with water, but, as clearly shown by an experiment of E. M. Rault, in aqueous solution, under the influence of light, at ordinary temperatures, it slowly changes into glucose; this alteration does not take place in the dark. (*P. J.*, Jan. 1872, p. 643.)

Cane sugar unites with the alkalies and some of the alkaline earths, forming definite combinations which render the sugar less liable to change. It also unites with lead monoxide. Boiled for a long time with aqueous solutions of potassium hydroxide, the liquid becomes brown, formic acid is produced, and two new acids are generated,—one brown or black and insoluble in water, called *melassic acid*, the other colorless and very soluble, named *glucic acid*. Alkalies and the alkaline earths are said to lessen the rotatory power of sugar in relation to polarized light, but the sugar recovers its power when the alkali is saturated. (*J. P. C.*, 4e sér., iv. 314.) The action of acids and alkalies on cane sugar explains the way in which lime acts in the manufacture and refining of sugar. The acids naturally existing in the saccharine juice have the effect of converting the cane sugar into uncrystallizable sugar, by which a loss of the former is sustained. The lime, by neutralizing these acids, prevents that result. An excess of lime, however, must be carefully avoided, as it injures the product of cane sugar in both quantity and quality. The change in sugar which precedes fermentation, namely, the conversion of cane sugar into the uncrystallizable kind, points to the necessity of operating on the juice before that process sets in, and hence the advantage of grinding canes immediately after they are cut, and boiling the juice at once.

Molasses is of two kinds, the West India and sugar-house. *West India molasses* is a black thick liquid, of a peculiar odor and sweet empyreumatic taste. When mixed with water and with the skimmings of the vessels used in the manufacture of sugar, it forms a liquor which, when fermented and distilled, yields rum. *Sugar-house molasses, golden drips, or grocer's syrup* is thicker than the West India molasses, and has a different flavor; as found in commerce, it is largely adulterated with glucose. Its sp. gr. is about 1.4, and it contains about 75 per cent. of solid matter. Both kinds of molasses contain uncrystallizable sugar, more or less cane sugar which has escaped separation in the process of manufacture or refining, and gummy and coloring matter.

Diabetic Sugar.—The sugar found in urine is almost exclusively dextrose, $C_6H_{12}O_6$. It may be recognized by its reducing action upon Trommer's solution or by Fehling's test, by its producing a yellow or brown color in contact with alkalies, slowly in the cold, rapidly on heating, by its uniting with phenylhydrazine to form a crystalline glucosazone, by its power of fermenting with yeast, and by its dextro-rotatory character. The tests for sugar in urine should always be preceded by tests for albumin, which latter, if present, should be removed by coagulation and filtration. Traces of sugar are said to be found normally in urine, but this never amounts to more than .01 per cent., while from 3 to 5 per cent. of reducing sugar is often found in the urine of persons suffering from diabetes mellitus.

Uses.—As an aliment and condiment cane sugar is enormously used by all civilized and semi-civilized nations. As a carbohydrate it is nearly equivalent to starch in its nutritive value, by its digestion largely adding to the fatty tissues of the body; but, as it contains no nitrogen, it is incapable of sustaining life by itself. It seems to be worked up in the alimentary canal with much more difficulty than other hydrocarbons, and its excessive use is very apt to lead to acid dyspepsia. *Glucose, or grape sugar*, on account of its lack of sweetness, is not much used for sweetening, but it exceeds cane sugar in food value on account of its being more readily digested.

As a demulcent, cane sugar has been used to some extent in *catarrhal affections*, especially of the respiratory tract, and S. A. Cartwright of New Orleans (*B. M. S. J.*, vols. xlvii. and li.), affirms that the vapor of boiling cane juice is of very great value in the treatment of *bronchitis and consumption*. According to S. Meslach, glucose, when given in doses of from six to six and a half ounces per day in the form of the concentrated syrup, acts as a powerful diuretic, and is very useful in the treatment of *cardiac dropsy*. If the kidneys be healthy, the glucose is said not to appear in the urine. The celebrated grape cure of Europe is said to act by virtue of the glucose in the grape.

The discovery of Minkowski (*T. M.*, 1892), that in dogs, after extirpation of the pancreas, levulose, given in moderate quantities, is consumed in the system, has led to the use of it as a food substitute for true sugar in *diabetes* with some success. As much as two ounces of it a day are sometimes well borne, but levulose frequently appears in the urine when more than one ounce has been given daily and rarely should this amount be exceeded.¹ According to Lepine, levulosuria is likely to occur when there is hepatic disease. Levulose has no direct influence upon the disease but is simply a useful and harmless addition to the dietetics. Under the name of *diabetin* it has been largely advertised as a proprietary preparation. Levulose has been strongly recommended in *phthisis*, in the dose of 4 to 6 tablespoonfuls a day, also as a substitute for sugar of milk for infants when an aperient property is not desired.

Sugar is much used for the purposes of preserving organic substances. It is probable that it acts by producing rapid exosmosis of the fluids of the fermentative organisms, its diluted solution being in fact prone itself to undergo fermentative change. All the different kinds of sugar susceptible of the alcoholic fermentation have this power. (Louis Mandl, *A. G. M.*, 5e sér., xvi. 49, Juillet, 1860.) In pharmacy, sugar is employed to render oils miscible with water, to cover the taste of medicines, to give them consistency, to preserve them from change, and to protect certain ferruginous preparations from oxidation. Accordingly, it enters into the composition of several mixtures, pills, and powders, of syrups and confections, and of all the troches. *Molasses* is used as an excipient for pills, and on account of its hygroscopic properties it prevents hardening.

Off. Prep.—Used in the preparation of official confections, pills, powders, masses, effervescent salts, mixtures, and many syrups.

SACCHARUM LACTIS. U. S., Br.

SUGAR OF MILK

(sāc'cha-rūm lăc'tis)

$C_{12}H_{22}O_{11} \cdot H_2O = 357.48$

"A peculiar crystalline sugar obtained from the whey of cows' milk by evaporation, and purified by recrystallization." *U. S.* "A crystallized sugar, $C_{12}H_{22}O_{11} \cdot H_2O$, obtained from the whey of milk." *Br.*

Lactin, Milk Sugar; Lactose; Sucre de Lait, *Fr.* Cod.; Saccharum Lactis, *P. G.*; Milchzucker, *G.*; Latosio, Zucchero di latte, *It.*; Lactosa, Azúcar de leche, *Sp.*

¹ According to J. B. Haycraft, patients with chronic diabetes can destroy 50 Gm. of levulose per diem. In some acute cases a part of the levulose given is burnt up, a part is changed into dextrose, and a third part passes as such into the urine. Rabbits can convert levulose into glycogen, the glycogen so formed accumulating in the liver. (*Zeit. f. Physiol. Chem.*, 1894.)

Preparation.—Sugar of milk is found only in milk, of which it forms about 5 per cent. (Boussingault). It is manufactured largely in Switzerland and the Bavarian Alps, especially from the whey left over in cheese making. In preparing it, milk is first coagulated by the addition of a little diluted sulphuric acid, and the resulting whey boiled down to about one-fifteenth of its original bulk into a brown, viscid, sweetly saline mass, which is put into tubs, where, in from twenty-four to forty-eight hours, the sugar crystallizes in a bright yellow granular mass, constituting the so-called "sugar-sand," which is afterwards decolorized by animal charcoal and repeated crystallizations. (*Am. Drug.*, Sept. 1884.) Within recent years the numerous "creameries" in the United States have produced milk sugar in such large quantities as a by-product that its importation from Switzerland has almost ceased. The American method of manufacturing sugar of milk is radically different from that followed abroad, and it thus described by LaWall (*Alumni Report Philadelphia Coll. Pharmacy*, April, 1902): The whey left after the first curdling of the milk (by the separator system) is run into vats, and treated with about 1 per cent. of hydrochloric acid to remove remaining proteid matters, the liquid being heated to the boiling point, and exactly neutralized with calcium hydroxide. The whey is then generally filtered through a filter press and evaporated in vacuo to a thick syrup, run into pans, and allowed to stand for two days, when granular crusts form. These are then centrifuged and washed with cold water to remove calcium chloride and soluble impurities, and the washings are reserved for future operations. The crude milk sugar is of a very light yellow color, and has little taste or odor. It is redissolved in water and the solution filtered through bone black in percolators. The colorless syrupy percolate is concentrated in vacuo to a pasty mass, which is placed in a centrifuge and washed with cold water. The mass is then dried on strainers in a drying chamber at 60° C. (140° F.), powdered in a ball mill, and bolted.

The casein obtained by acidulation of the skim milk, and subsidence, is washed and heated with water containing a small amount of sulphuric acid, to remove impurities. The moist pulpy mass left after the removal of the water is then shredded by means of cutting knives run by a high-speed engine, the flakes being removed in wire gauze frames and rapidly dried with a current of air at 140° F. It is then powdered with high-speed disintegrators. See a paper on the American Milk Product Industry by J. W. England. (*Proc. A. Ph. A.*, 1902, 354.)

Properties.—In "white, hard, crystalline masses, or a white powder feeling gritty on the tongue, odorless, and having a faintly sweet taste. Permanent in the air. On incinerating a portion, the percentage of ash remaining should not exceed 0.25 percent. Soluble in 4.79 parts of water at 25° C. (77° F.), and in 1

part of boiling water; insoluble in absolute alcohol, ether, or chloroform. An aqueous solution of Sugar of Milk is neutral to litmus paper, and is dextrogyrate. On adding to 5 Cc. of a hot, saturated aqueous solution of Sugar of Milk an equal volume of sodium hydroxide T.S., and gently warming, the liquid will turn yellow and finally brownish-red. On the further addition of a few drops of cupric sulphate T.S., a brick-red precipitate will appear. If about 1 Gm. of powdered Sugar of Milk be sprinkled upon about 5 Cc. of cold sulphuric acid (sp. gr. 1.84) contained in a flat-bottomed dish, and covered with a watch-glass, the acid may acquire a greenish or reddish, but no brown or brownish-black color within half an hour (absence of *cane-sugar*). An aqueous solution of Sugar of Milk (1 in 10) mixed with a few drops of hydrochloric acid should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If 1 Gm. of powdered Sugar of Milk be boiled for five minutes with 50 Cc. of distilled water and the solution cooled, no blue coloration should be produced upon the addition of one drop of iodine T.S. (absence of *starch*)." *U. S.* "In crystals or in crystalline masses, grayish-white, hard, odorless, faintly sweet. Soluble in 7 parts of cold water, and in about 1 part of boiling water. It should not leave more than 0.25 per cent. of ash when incinerated with free access of air. 1 gramme dissolved in 10 cubic centimetres of water gives a red color with solution of phenol-phthalein after the addition of three drops of the volumetric solution of sodium hydroxide (limit of lactic acid)." *Br.*

In commerce sugar of milk frequently occurs in cylindrical masses, the axis of which is a wooden stick, around which the crystals have been deposited. Experiments have shown that much of the milk sugar of commerce contains micro-organisms which have resulted from the decomposition of animal constituents in milk, and the tests of the Pharmacopœias do not exclude such impurities. (*D. C.*, 1893, 250; *Bull. Pharm.*, 1893, v. 5; *P. J.*, 1894, 853.) Its sp. gr. is 1.54. It is not susceptible of the vinous fermentation by the direct influence of yeast; but after the action of dilute acids, which first convert it into a variety of glucose, it is capable of furnishing a spirituous liquor. It is well known that both mares' and cows' milk, after becoming sour, are capable of forming an intoxicating drink, by fermentation. By the action of nitric acid, sugar of milk is converted into mucic acid. When anhydrous it consists of $C_{12}H_{22}O_{11}$; when crystallized, of $C_{12}H_{22}O_{11} + H_2O$. (Staedeler and Krause.) These formulas make anhydrous sugar of milk isomeric with cane sugar. Sugar of milk, when treated with weak sulphuric acid, is inverted or changed into a mixture of galactose and dextrose, both of the formula $C_6H_{12}O_6$. The galactose crystallizes in fine needles, fusing at 163° C. (325.4° F.).

Sugar of milk is sometimes adulterated with cane sugar or glucose; Hynson and Dunning (*Proc. A. Ph. A.*, 1901, 207) give the following tests for cane sugar and glucose: The test solution is composed of resorcinol 3 parts, hydrochloric acid 1 part, alcohol 100 parts. Dissolve 0.1 Gm. of the suspected milk sugar in a few drops of water contained in a porcelain dish and add to this solution 5 or 6 drops of the test solution. Evaporate slowly over a spirit lamp and allow the outer edge of the solution to boil a little, then tip the dish to one side. On the surface left moist by the receding liquid continue the heat gently. If a trace of cane sugar be present there will appear flashes of vermilion color over the surface treated. If there be an appreciable amount (5 to 10 per cent.) of cane sugar present, a vermilion mirror will be formed which can be more clearly seen upon carefully evaporating the entire solution. The evaporation must take place slowly as the sugars will easily char if exposed to too much heat. A brownish red color quickly charring and not spreading must not be mistaken for cane sugar. This coloration is caused by the milk sugar but need not be confused with the vermilion coloration of cane sugar.

Uses.—Sugar of milk has been recommended as a non-nitrogenous, bland article of diet in consumption and other wasting diseases, especially when there is extreme irritability of the stomach. According to S. Meslach, Zavadsky, and Germajn Sée, it is an active hydragogue diuretic, which may often be used with great advantage in the treatment of cardiac dropsy. If the kidneys be sound, the lactose is said not to appear in the urine. It has been given by the authorities quoted in doses varying from three-quarters of an ounce to six ounces a day, administered in concentrated syrup or in milk.

Off. Prep.—Used as a diluent in *Extractum Nucis Vomice*, *U. S.*, *Br.*; *Extractum Opii*, *U. S.*; *Extractum Physostigmatis*, *Br.*; *Extractum Quassia*, *U. S.*; *Extractum Strophanthi*, *Br.*; *Pilula Podophylli*, *Belladonnae et Capsici*, *U. S.*; *Pulvis Ipecacuanhae et Opii*, *U. S.*; *Trituratio Elaterini*, *U. S.* (*Br.*).

SAFROLUM. U. S.

SAFROL [Synthetic Oil of Sassafras]

(săf-rô'lŭm)

$C_{10}H_{10}O_2 = 160.86$

"The methylene ether of allyl pyrocatechol [$C_6H_5.C_6H_5.(OOCH_3)$ 1:3:4], found in oil of sassafras, camphor oil, and other volatile oils, purified, if necessary, by repeated chilling and crystallization." *U. S.*

Safrol, *Fr.*, *G.*

Preparation.—Safrol is found in oil of sassafras often in the proportion of 80 per cent., but commercially it is obtained from the red oil of camphor, by fractional distillation, the

portion boiling at about 230° C. (446° F.) contains the safrol, this is cooled and the crystals separated. (See *Oleum Sassafras*, p. 875.)

Properties.—It is officially described as "a colorless or faintly yellow liquid with a sassafras-like odor. Specific gravity: 1.105 to 1.106 at 25° C. (77° F.). Boiling point: about 233° C. (451.4° F.). It is optically inactive. On cooling to -20° C. (-4° F.) or below, it solidifies to a mass of crystals, which do not melt below 11° C. (51.8° F.). Soluble in about an equal volume of strong alcohol, and in about 30 parts of 70 percent. alcohol. Miscible in all proportions with ether and chloroform." *U. S.* Physiologically and therapeutically, safrol is equivalent to oil of sassafras.

Dose, five to ten minims (0.3 to 0.6 Cc.).

SALICINUM. U. S., *Br.*

SALICIN

(săl-i-cī'nŭm)

$C_{13}H_{18}O_7 = 283.99$

"A glucoside obtained from several species of *Salix* and *Populus* (Fam. *Salicaceae*). Salicin should be kept in well-stoppered bottles." *U. S.* "A crystalline glucoside, $C_{13}H_{18}O_5.O.C_6H_4.CH_2OH$, obtainable from the bark of various species of *Salix*, and of *Populus*." *Br.*

Orthohydroxybenzylglucoside; *Salicine*, *Fr.*; *Salicin*, *G.*; *Salleina*, *It.*

The discovery of salicin is claimed by Buchner of Germany, and Fontana and Rigatelli of Italy; but Leroux of France, deserves the credit of having first accurately investigated its properties. The following is Merck's process for its extraction. A boiling concentrated decoction of the bark is treated with litharge until it becomes nearly colorless. Gum, tannin, and extractive matter, which would impede the crystallization of the salicin, are thus removed from the liquid, while a portion of the oxide is dissolved in combination probably with the salicin. To separate this portion of oxide, sulphuric acid is first added, and then barium sulphide, and the liquor is filtered and evaporated. Salicin is deposited, and may be purified by repeated solution and crystallization. Erdmann has given another process. Sixteen ounces of the bark are macerated for twenty-four hours in four quarts of water mixed with two ounces of lime, and the whole is then boiled for half an hour. The process is repeated with the residue. The decoctions having been mixed, and allowed to become clear by subsidence, the liquor is poured off, concentrated to a quart, then digested with eight ounces of ivory black, filtered, and evaporated to dryness. The extract is exhausted by spirit containing 28 per cent. of alcohol, and the tincture evaporated so that the salicin may crystallize. This is purified by again dissolving, treating with ivory black, and crystallizing.

Merck obtained 251 grains from 16 ounces of the bark and young twigs of *Salix Helix*, and Erdmann 300 grains from the same quantity of the bark of *Salix pentandra*. It may probably be obtained from any of the willow barks having a bitter taste. T. Fawcett states that the best material for preparing salicin is undoubtedly the willow peelings, obtained "as refuse from a basket factory, and known in Belgium as "rood schors." David Brown states that the peelings are produced from *Salix fragilis*, while Crispo considers the source to be *Salix purpurea*. These peelings should be used soon after they are stripped from the twigs, and the method of preparing salicin may be conducted as follows: Macerate willow peelings in water for some hours at a temperature as much below the boiling-point as will exhaust them. Strain and remove all moisture from the mass by hydraulic pressure. Evaporate the fluidextract thus formed to a low bulk (*in vacuo*). Precipitate the tannin and extractive by treating the liquid successively with quick lime, lead acetate and lead subacetate, in the order named. Remove an excess of any of these precipitants with oxalic acid. Filter and evaporate the clear solution until crystals appear. This treatment generally sufficed to obtain a satisfactory product, but sometimes a final purification with animal charcoal was necessary. (P. J., June 6, 1903, 784.) For a paper by Jowett on the percentage of salicin obtained from various kinds of willow bark see Y. B. P., 1902, 483, and 1903, 474. Braconnot procured it from various species of *Populus*, particularly *P. tremula*, or European aspen.

Properties.—When pure, salicin is in white, shining, slender crystals, inodorous, but very bitter, with the peculiar flavor of the bark. It is soluble in cold water, much more so in boiling water, soluble in alcohol, and insoluble in ether and oil of turpentine. It neutralizes neither acids nor salifiable bases, and is not precipitated by any reagent. Concentrated sulphuric acid decomposes it, receiving from it an intense and permanent bright-red color, and producing a new compound called *rutulin*. It is officially described as in "colorless, silky, shining, crystalline needles, rhombic prisms, or a white crystalline powder; odorless, and having a very bitter taste. Soluble in 21 parts of water, and in 71 parts of alcohol at 25° C. (77° F.), in 3.3 parts of water at 80° C. (176° F.), and in 22 parts of alcohol at 60° C. (140° F.); insoluble in ether and chloroform. It melts at 201.4° C. (394.5° F.). Upon ignition, it is consumed, leaving no residue. Its aqueous solution is levogyrate and neutral to litmus paper. On heating a small portion of Salicin in a test-tube until it turns brown, then adding a few Cc. of water, and afterwards a drop of ferric chloride T.S., a violet color will be produced. Sulphuric acid produces a red color, which disappears upon the addition of water. Upon gently heating

0.1 Gm. of Salicin with 0.2 Gm. of potassium dichromate and 2 Cc. of diluted sulphuric acid, the odor of salicylic aldehyde will be developed. Sulphuric acid containing a trace of molybdic acid produces with Salicin a violet color, changing to a deep brownish-red. Sulphuric acid containing a trace of potassium iodate produces a dark red color, changing to deep purple. Sulphuric acid containing about one-fifth of its volume of solution of formaldehyde produces a deep purplish-red color. If to a small quantity of Salicin a few drops of nitric acid be added, the liquid evaporated to dryness, and the resulting yellowish residue treated with ammonia water and heated upon a water-bath with a fragment of potassium cyanide, a blood-red color will be developed. The aqueous solution of Salicin is not precipitated by tannic or picric acid T.S., nor by mercuric potassium iodide T.S. (absence of, and difference from, *alkaloids*)." U. S. "Colorless shining trimetric tabular crystals, with a very bitter taste. Soluble in 28 parts of cold water or 60 parts of alcohol (90 per cent.); insoluble in ether. Colored red by sulphuric acid. A small quantity heated with a little potassium bichromate, a few drops of sulphuric acid, and some water, yields salicylic aldehyde, recognizable by its odor of meadow-sweet. The crystals melt when heated, and evolve salicylic aldehyde. On heating to redness in air they leave no residue (absence of mineral impurity)." Br. It belongs to the class of glucosides, being resolved by boiling with diluted hydrochloric and sulphuric acids into grape sugar and *saligenin*, according to the reaction:

Saligenin, which is ortho-oxybenzyl alcohol, $\text{C}_6\text{H}_4(\text{OH})\text{CH}_2\text{OH}$, is converted by further boiling with dilute acids into a resinous body, *saliretin*, $\text{C}_{14}\text{H}_{14}\text{O}_8$. Nitric acid produces with salicin at first two principles called respectively *helicin*, $\text{C}_{13}\text{H}_{18}\text{O}_7$, and *helicoidin*, $\text{C}_{10}\text{H}_{14}\text{O}_{14}$, and afterwards picric and oxalic acids. (J. P. C., xxx. 43.) Distilled with potassium dichromate and sulphuric acid, salicin yields, among other products, a volatile oleaginous liquid, identical with one of the components of oil of spirea, and recognized as *salicyl aldehyde*, $\text{C}_7\text{H}_6\text{O}_2$ (*salicylous acid*), while saligenin, $\text{C}_7\text{H}_6\text{O}_3$, is the alcohol, and salicylic acid, $\text{C}_7\text{H}_5\text{O}_3$, the acid corresponding. The synthesis of salicin has been effected by Michael (A. J. P., 1879, 492), who obtained first *helicin* by the reaction of acetochlorhydrase and salicyl aldehyde, and, by the action of nascent hydrogen upon this, salicin.

Uses.—Salicin acts upon the stomach probably as a simple bitter, and after absorption as a feeble and uncertain form of salicylic acid, since it is rapidly, although not completely, decomposed in the system, the products of its change appearing in the urine fifteen to thirty minutes after the ingestion of a single dose. The elimination is partly as salicin, partly as salicylic acid, partly as a salicyluric acid, and

partly as saligenin. It has been highly recommended as a substitute for salicylic acid in *rheumatism* by MacLagan and others, but since it owes its activity to its conversion in the blood into salicylic acid and since this conversion is uncertain, salicin is greatly inferior to the salicylates, and is at present rarely employed. Salicin has been used as an antiperiodic. One or two drachms may be given in the intermission.

Dose, from ten to thirty grains (0.65 to 2.0 Gm.).

SALVIA. U. S.

SALVIA [Sage]

(sāl'vī-ā)

"The dried leaves of *Salvia officinalis* Linné (Fam. Labiatæ)." U. S.

Garden Sage, Meadow Sage, Save, Picked Sage; Sauge officinale, *Fr. Cod.*; Sauge, *Fr.*; Folia Salvise, *P. G.*; Salbeiblätter, *Salbel, G.*; Salvia, *It., Sp.*

Salvia officinalis, L., *Sp. Pl.* (1753) 23; Willd., *Sp. Plant.* i. 129; B. & T. 206.—Common garden sage is a perennial plant, about two feet high, with a quadrangular, pubescent, branching, shrubby stem, furnished with opposite, petiolate, ovate-lanceolate, crenulate, wrinkled leaves, of a grayish-green color, sometimes tinged with red or purple. The flowers are blue, variegated with white and purple, and are disposed on long terminal spikes, in distant whorls, each composed of a few flowers, and provided with ovate, acute, deciduous bracts. The calyx is tubular and striated, with two lips, of which the upper has three acute teeth, the under two. The corolla is tubular, bilabiate, ringent, with the upper lip concave, and the lower divided into three rounded lobes, of which the middle is the largest. The filaments are supported upon short pedicels, to which they are affixed transversely at the middle.

Sage grows spontaneously in Southern Europe, and is cultivated abundantly in our gardens. There are several varieties, differing in the size and color of their flowers, but all possessing the same medicinal properties. The flowering period is in June, at which time the plant should be cut, and dried in a shady place. The leaves are officially described as "long and stoutly petiolate, the blade elliptical or ovate-oblong, 3 to 7 Cm. long, obtuse or subacute at the summit, rounded or subcordate at the base, finely crenulate, thick, grayish-green, very pubescent, especially on the under surface, conspicuously reticulate-veined; odor aromatic; taste aromatic, bitter, and somewhat astringent." U. S.

Both these and the flowering summits have a strong, fragrant odor, and a warm, bitterish, aromatic, somewhat astringent taste. They abound in a volatile oil, which may be obtained separate by distillation with water. Muir (*J. Chem. S.*, 37, p. 678) found it to contain a

terpene boiling at 156° C. (312.8° F.), another boiling at 171° C. (339.8° F.), *thujone*, $C_{10}H_{16}O$, a liquid boiling at from 197° to 203° C., and ordinary camphor, $C_{10}H_{16}O$. In the fresh oil the first terpene predominates. On standing, the amount of *thujone* increases, and then the camphor. The oil from English leaves contains also a sesquiterpene, $C_{15}H_{24}$, of the boiling point 260° C. (500° F.). Wallach (*Ann. Ch. Ph.*, 1889) states that the first portions contain *pinene* and *cineol*, but the greater portion consists of *thujone*, $C_{10}H_{16}O$ (formerly called *salviol*). Ferrous sulphate strikes a black color with infusion of sage.

Uses.—Sage unites slightly tonic, astringent, and aromatic properties. By the ancients it was highly esteemed; it is at present little used, except as a condiment, but has been given in *dyspepsia*, also for *colliquative sweats*. The dose of the powdered leaves is from twenty to sixty grains (1.3 to 3.9 Gm.). Dose of the infusion (1 oz. in 1 pint of boiling water), two fluidounces (60 Cc.). According to Cadéac and Meunier (*Lyons Méd.*, May, 1891), the volatile oil of sage is a violent epileptiform convulsant, resembling in its action the oil of absinthe, but less powerful.

Dose, from twenty to sixty grains (1.3 to 3.9 Gm.).

SAMBUCCI FLORES. Br.

ELDER FLOWERS

(sām-bū'cī flō'rēs)

"The flowers of *Sambucus nigra*, Linn., separated from the stalks." Br.

Sambucus, Elder, U. S. 1890; Sweet Elder, Black Elderberry; Sureau, *Fr. Cod.*; Fleurs de Sureau. Hollunder, Fliederblumen, *G.*; Sambuco, *It.*; Sauco (Flor de), *Sp.*

Sambucus nigra, L., Willd., *Sp. Plant.* i. 1595; B. & T. 137.—The common elder of Europe differs from the American most obviously in its size, the former approaching in height that of a small tree. The stem is much branched towards the top, and has a rough whitish bark. The leaves are narrower. The flowers are small, whitish and in five-parted cymes. The ovary consists of but three carpels, there being five cells in *S. canadensis*, L. The berries are larger in the European elder, globular, and blackish purple when ripe.¹ G. De Sanctis (*Gazz. Chim. Ital.*, 1895, xxv. 1, vol. xlix.) obtained conine from the leaves and stems of *Sambucus nigra*.

Sambucus canadensis, L., *Sp. Pl.* (1753) 269; Willd., *Sp. Plant.* i. 1494; B. & T. 138. The flowers of our indigenous common elder were dropped from the U. S. P. at the Eighth

¹ A fungus growing on this plant, called *fungus sambuci*, has been used as a local application in *conjunctivitis*. According to Steckel, it is capable of taking up from 9 to 12 times its weight of water. (*N. R. Pharm.*, xiii. 476, 1864.)

Revision. The plant is a shrub from six to ten feet high, with a branching stem, covered with a rough gray bark, and containing a large spongy pith. The small branches and leaf-stalks are very smooth. The leaves are opposite, pinnate, sometimes bipinnate, and composed usually of five to nine oblong-oval, acuminate, smooth, shining, deep-green leaflets; the veins of the under surface are somewhat pubescent. The flowers are small, white, and disposed in loose cymes; the cream-colored corolla is wheel-shaped, with five stamens on the tube. The berries are small, globular, and deep purple when ripe. The shrubs grow in low, moist grounds, along fences, and on the borders of small streams, throughout the United States, from Canada to the Carolinas, and westward as far as Arizona and Texas. It flowers from May to July, and ripens its fruit early in autumn. The flowers, which are official in the Br. Pharm., have an aromatic though rather heavy odor. The berries as well as other parts of the plant are employed, in domestic practice, for the same purposes as the corresponding parts of the European elder, to which this species bears a close affinity.

Properties.—The British Pharmacopœia thus describes elder flowers: "Elder Flowers are small; calyx superior, five-toothed; corolla flat, rotate, deeply five-lobed, creamy-white, with five stamens inserted within the tube; anthers yellow. They have a slightly bitter taste, and a sweet, faint, not altogether agreeable odor." Br. The flowers of *S. canadensis* were described in the U. S. Pharmacopœia 1890 as follows:

"The flowers are, when fresh, about 5 Mm. broad, and after drying shrivelled; calyx superior; minutely five-toothed; corolla originally cream-colored, after drying pale brownish-yellow, wheel-shaped and five-lobed, with five stamens on the short tube; odor peculiar; taste sweetish, somewhat aromatic and bitterish. The peduncles and pedicels of the inflorescence should be rejected." U. S. 1890. The flowers yield their active properties to water by infusion, and when distilled give over a small proportion of volatile oil, which on cooling assumes a butyraceous consistence and contains an appreciable portion of ammonia. The berries are nearly inodorous, but have a sweetish, acidulous taste, dependent on the presence of saccharine matter and malic acid. Their expressed juice is susceptible of fermentation, and forms a vinous liquor used in Northern Europe. It is colored violet by alkalies, and bright red by acids, and the coloring matter is precipitated blue by lead acetate. The inner bark is without odor. Its taste is at first sweetish, afterwards slightly bitter, acrid, and nauseous. Both water and alcohol extract its virtues, which are said to reside especially in the green layer between the liber and the epidermis. According to Simon, the active principle of the inner bark of the root is a soft resin, which

may be obtained by exhausting the powdered bark with alcohol, filtering the tincture, evaporating to the consistence of syrup, then adding ether, which dissolves the active matter, and finally evaporating to the consistence of a thick extract. Of this, twenty grains produce brisk vomiting and purging. (*Ann. Ph. Ch.*, xxxi. 262.) The bark, analyzed by Kramer, yielded an acid called by him *viburnic acid* (which has proved to be identical with *valeric acid*), traces of volatile oil, albumen, resin, fat, wax, chlorophyll, tannic acid, grape sugar, gum, extractive, starch, pectin, and various alkaline and earthy salts. (*Chem. Gaz.*, May, 1846; from *A. Pharm.*) C. G. Traub found in the bark valeric acid, volatile oil, fat, resin, tannin, sugar, and coloring matter. (*A. J. P.*, 1881, p. 392.) J. B. Metzgar made a partial examination of the fruit and found sugar, gum, tannin, fat, and a resinous body. (*A. J. P.*, 1881, p. 553.) It was also examined by F. F. Lyons (*A. J. P.*, 1892, p. 1), who found 0.5 per cent. of a volatile oil, an amorphous yellow compound of a glucosidal character, and a tannin. The volatile oil of elder flowers was examined by W. J. Bush & Co. (*C. D.*, 1897, 53.) It has the sp. gr. 0.827, and is solid at ordinary temperatures like oil of rose. The liquid portion possesses the fragrance of fresh elder blossoms.

Uses.—The flowers are gently excitant and sudorific, but are seldom used. The berries are diaphoretic and aperient, and their inspissated juice has been used as an alternative in *rheumatism* and *syphilis* in doses of from one to two drachms (3.9 to 7.7 Gm.); also as a laxative in doses of half an ounce (15.5 Gm.) or more. The inner bark is a hydragogue cathartic, and in large doses emetic. It has been employed in *dropsy*, *epilepsy*, and as an alternative in various chronic diseases. An ounce may be boiled with two pints of water to a pint, and four fluidounces (118 Cc.) given for a dose. It is also used in vinous infusion. The leaves are not without activity, and the young leaf-buds are said to be a violent and even unsafe purgative. The juice of the root has been highly recommended in *dropsy* as a hydragogue cathartic, sometimes acting as an emetic, in the dose of a tablespoonful, repeated *pro re nata*. The fruits of the California species *S. glauca* and *S. racemosa* are said to be used as food by the Indians. According to Combemale, confirmed by Lemoine, the aqueous solution of the European elder, *S. nigra*, is a very active diuretic, also causing in the lower animals, when given in sufficient amount, a pronounced fall of temperature, pulse, and respiration. It was found very useful in *cardiac* and *renal dropsies*. The drug itself sometimes caused vomiting and purging, but this effect never followed the use of the decoction.

Dose, from one to two drachms (3.9 to 7.7 Gm.); as a laxative, half an ounce (15.5 Gm.) or more.

Off. Prep.—Aqua Sambuci, Br.

SANGUINARIA. U. S.

SANGUINARIA (Bloodroot)

(sân-gui-nă-ti-ă)

"The dried rhizome of *Sanguinaria canadensis* Linné (Fam. *Papaveraceæ*), collected after the death of the foliage." U. S.

Red Puccoon, Tetterwort, Red Indian Paint; Sangulnaire, Fr.; Blutwurz, G.

Sanguinaria canadensis, L., *Sp. Pl.* (1753) 505; Willd., *Sp. Plant.* ii. 1140; Bigelow, *Am. Med. Bot.*, i. 75; Barton, *Med Bot.*, i. 31; B. & T. 20.—The bloodroot, or, as it is sometimes called, *puccoon*, is an herbaceous or perennial plant. The root (rhizome) is horizontal, abrupt, often contorted, about as thick as the finger, two or three inches long, fleshy, of a reddish-brown color on the outside, and brighter red within. It is furnished with numerous slender roots, and makes offsets from the sides, which succeed the old plant. From the end of the rhizome arise the scape and leaf-stalks, surrounded by the large sheaths of the bud. These spring up together, the folded leaf enveloping the flower-bud, and rolling back as the latter expands. The leaf, which stands upon a long channelled petiole, is reniform, somewhat heart-shaped, deeply lobed, smooth, yellowish green on the upper surface, paler or glaucous on the under, and strongly marked by orange-colored veins. The scape is erect, round, and smooth, rising from a few inches to a foot, and terminating in a single flower. The calyx is two-leaved and deciduous. The petals, varying from seven to fourteen, but usually about eight in number, are spreading, ovate, obtuse, concave, mostly white, but sometimes slightly tinged with rose or purple. The stamens are numerous, with yellow filaments shorter than the corolla, and orange oblong anthers. The ovary is oblong and compressed, with a sessile, persistent stigma. The capsule is oblong, acute at both ends, one-celled, two-valved, and contains numerous oval, reddish-brown seeds. The whole plant is pervaded by an orange-colored sap, which flows from every part when broken, but is of the deepest color in the rhizome. The bloodroot is one of the earliest and most beautiful spring flowers of the Northern United States, growing abundantly in loose, rich soils and shady situations. After the fall of the flower the leaves continue to grow, and by the middle of summer have become so large as to give the plant an entirely different aspect. Except the seeds, all parts of the plant are active.

The dried rhizome is in pieces from one to three inches long, from a quarter to half an inch or more in thickness, flattened, faintly annulated, much wrinkled and twisted, often furnished with abrupt offsets and many short fibres, of a reddish-brown color externally, with a spongy uneven fracture, the surface of which is at first bright orange, or whitish, with nu-

merous small red resin-cells, but becomes of a dull brown by long exposure. It is officially described as "of horizontal growth, cylindrical, often somewhat branched, 2 to 7 Cm. long, 5 to 15 Mm. in diameter; externally reddish-brown, slightly annulate; fracture short and somewhat waxy, brownish-red, or yellowish-white with numerous reddish resin cells; odor slight, the powder sternutatory; taste persistently acrid and bitter." U. S. For an interesting microscopical description of the rhizome by E. S. Bastin, see *Pharm.*, 1885, p. 201. The color of the powder is a brownish orange-red. *Sanguinaria* has a faint narcotic odor, and a bitterish very acrid taste, the pungency of which remains long in the mouth and fauces. It yields its virtues to water and alcohol. Dana of New York, obtained from it an alkaloid, denominated by him *sanguinarine*, by infusing the finely powdered root in hot water or diluted hydrochloric or acetic acid, precipitating with ammonia water, collecting the precipitated matter, boiling it in water with pure animal charcoal, filtering off the water, treating the residue left upon the filter with alcohol, and finally evaporating the alcoholic solution. (*Ann. Lyc. of Nat. Hist. New York*, ii. 250.) It may also be conveniently procured by a process similar to that employed by Probst for obtaining chelerythrine from celandine. This consists in forming a strong ethereal tincture of the root, passing through this hydrochloric acid gas, drying the precipitated hydrochloride, which is insoluble in ether, dissolving it in hot water, filtering, precipitating by ammonia, drying the precipitate, dissolving it in ether, decolorizing by animal charcoal, precipitating by means of hydrochloric acid gas, and decomposing the hydrochloride as before. (*Chem. Gaz.*, i. 145.)

G. König (*A. J. P.*, 1891, p. 457) has reinvestigated the constituents of *S. canadensis* and gave us a clear understanding of them. He found *chelerythrine*, which is present in greatest quantity, *sanguinarine*, β - and γ -homochelidonine, and *protopine*. Chelerythrine crystallizes with a molecule of alcohol which is not separated at 150° C. Its formula is $C_{21}H_{17}NO_4$, and it is identical with the alkaloid extracted from *Chelidonium majus*. The salts are lemon-yellow. Sanguinarine has the formula $C_{20}H_{15}NO_4$ (Schmidt, $C_{19}H_{15}NO_4$), and is very similar to chelerythrine in its properties. It crystallizes with one-half molecule of H_2O , and melts at 211° C. Its salts are red. The base named γ -homochelidonine is probably identical with that separated by Selle from *Chelidonium majus*, and its formula is $C_{22}H_{21}NO_4$. The fourth alkaloid, *protopine*, has been prepared from *Chelidonium majus*, from *Sanguinaria canadensis*, and from opium, all three of the specimens being identical. Its formula is $C_{20}H_{17}NO_5$, and it melts at 204° C. The virtues of the root are said to be rapidly deteriorated by time. Thos. M. Newbold extracted from *sanguinaria* a non-volatile liquid acid (*sanguinarinic acid*) (*A. J. P.*, 1866, p. 496), which

L. C. Hopp has shown to be a solution of impure citric and malic acids. Schlotterbeck (*Ph. Rev.*, 1900, 358) examined sanguinarine nitrate of commerce and found it to consist mainly of chelerythrine, with some sanguinarine and traces of protopine and homochelidonine; he believes that chelerythrine should be called sanguinarine. For methods of assay of sanguinaria see *A. J. P.*, 1896, 305; *M. R.*, 1900, 451; *Proc. A. Ph. A.*, 1903, 284.

Uses.—Sanguinaria is an acrid emetic, with stimulant narcotic powers. In small doses it excites the stomach and accelerates the circulation; more largely given, it produces nausea and consequent depression of the pulse, and in the full dose it occasions active vomiting. It is also expectorant, and is said to be emmenagogue. The effects of an overdose are violent emesis, a burning sensation in the stomach, tormenting thirst, faintness, vertigo, dimness of vision, and alarming prostration. (For fatal cases, see *Am. J. M. S.*, N. S., ii. 506.) Snuffed up the nostrils, bloodroot excites much irritation, attended with sneezing. Upon fungous surfaces it acts as an escharotic. It has been used in various diseases, but is at present never employed, except as a stimulant expectorant in chronic bronchitis or in the advanced stages of the acute disorder. Twenty grains (1.3 Gm.) of it are said to usually act as a violent emetic.

Wm. Tully found the alkaloid *sanguinarine* (chelerythrine) to produce vertigo, dilatation of the pupil, a haggard expression of the face, nausea, coldness of the extremities, cold sweats, and diminished frequency with irregularity of the pulse. R. P. Thomas of Philadelphia, who experimented with it on himself and others, gave the following statement of its powers. In doses varying from one-twelfth to one-eighth of a grain (0.005 to 0.008 Gm.) it acted as an expectorant, without disturbing the stomach. One-sixth or one-fourth of a grain (0.01 to 0.016 Gm.), given every two or three hours, generally produced nausea, and sometimes vomiting. Half a grain (0.032 Gm.) in solution, given at intervals of ten minutes, almost invariably vomited after the second or third dose. Under the influence of one-eighth or one-sixth of a grain (0.008 or 0.01 Gm.), given every three hours, for two days or more, the pulse was generally reduced from five to fifteen beats in the minute. He found no alternative effect, and none of any kind directly upon the liver. (*Proc. Am. Med. Ass.*, 1863, p. 219.) Robert Meade Smith found that the alkaloid in large doses produced in mammals vomiting, purging, collapse, convulsions, and death from asphyxia, the convulsions being spinal, but associated with loss of reflex activity and depression of the spinal motor centres. The same authority states that moderate doses cause a rise of arterial pressure by stimulation of the vasomotor centre, while toxic doses depress the pressure, partly by a direct action upon the heart, partly by paralyzing the vasomotor centres. Hans

Meyer (*A. E. P. P.*, xxix.) found in the frog that sanguinarine first stimulates and then paralyzes spinal-motor ganglia; on the blood pressure it acted much as described by Smith.¹ Sanguinaria is rarely given in substance.

Dose, U. S. P., two grains (0.13 Gm.).

Pterocarpus santalinus, L., *Sp. Pl.* (1871) 318; Willd., *Sp. Plant.* iii. 906; Woody., *Med. Bot.* 430, t. 156; B. & T. 82.—This is a large tree, with alternate branches, and petiolate ternate leaves, each leaflet being ovate, blunt, somewhat notched at the apex, entire, veined, smooth on the upper surface, and hoary beneath. The flowers are yellow in axillary spikes, and have a papilionaceous corolla, of which the vexillum is obcordate, erect, somewhat reflexed at the sides, toothed and waved, the alæ spreading with their edges apparently toothed, and the carina oblong, short, and somewhat inflated. The tree is a native of India, attaining the highest perfection in mountainous districts, and inhabiting especially the mountains of Coromandel and Ceylon. It is said that it is everywhere rare, and that plantations of it are being formed. Its wood is the official *red saunders*, though there is reason to believe that the products of other trees are also sold by the same name.

The wood comes in heavy, irregular, roundish or angular billets of various size and thickness,

¹ *Acetum Sanguinariae*, U. S. 1880. *Vinegar of Sanguinaria*. (*Vinaigre de Sanguinaire*, Fr.; *Blut-wurzel-Essig*, G.)—"Sanguinaria, In No. 30 powder, ten parts [or one and three-fourths ounces av.]; Diluted Acetic Acid, a sufficient quantity, to make one hundred parts [or one pint]. Moisten the powder with *fec* parts [or one fluidounce] of Diluted Acetic Acid, pack it firmly in a conical glass percolator, and gradually pour Diluted Acetic Acid upon it until one hundred parts [or one pint] of filtered liquid are obtained." U. S. 1880. *Vinegar of Sanguinaria* may also be prepared by macerating the powder in one pint of Diluted Acetic Acid for seven days, expressing the liquid, and filtering through paper. It is efficient, and of a deep-red color. On standing, a deposit is always noticed upon the sides of the vessel containing it, and the color pales.

A syrup may be formed from this vinegar by the addition of sugar, as in the syrup of squill. The dose of the vinegar of bloodroot as an emetic is three or four fluidrachms (11.25 or 15 Cc.); as an alternative and expectorant, from fifteen to thirty minims (0.9 to 1.8 Cc.). It has been used as a local remedy in ringworm and other cutaneous diseases, and has been found by R. G. Jennings efficient as a gargle in the sore throat of scarlet fever.

externally brown from exposure, internally of a deep blood-red color, on transverse section variegated with zones of a lighter red. The structure is heavy, compact, and fibrous. In the pharmacies red saunders is usually kept in the shape of small chips, or raspings, or coarse powder, of a deep reddish-brown color, slightly astringent in taste, and when rubbed of a faint peculiar odor. It has little odor or taste. Red saunders is officially described as follows: "Usually in chips, or a coarse, brownish-red powder; in transverse section slightly radiate, with numerous concentric rings, the medullary rays being 1 cell in width; nearly inodorous and almost tasteless. Red Saunders imparts a red color to alcohol, but not to water." *U. S.* It imparts a red color to alcohol, ether, and alkaline solutions, but not to water, and a test is thus afforded by which it may be distinguished from some other coloring woods. The alcoholic tincture produces a deep violet precipitate with ferrous sulphate, a scarlet with mercuric chloride, and a violet with the soluble salts of lead. The coloring principle, which was separated by Pelletier and called by him *santalin*, is of a resinous character, scarcely soluble in cold water, more so in boiling water, very soluble in alcohol, ether, acetic acid, and alkaline solutions, but slightly in the fixed and volatile oils, with the exception of those of lavender and rosemary, which readily dissolve it. It is precipitated when acids are added to the infusion of the wood, prepared with an alkaline solution. Weyermann and Haefely have found it to possess acid properties, and give it the formula $C_{15}H_{14}O_5$. (*Ann. Ch. Ph.*, 74, p. 226.) Weidel (*Wien. Akad. Ber.*, lx. p. 388), by extracting the red saunders with potassium hydroxide, precipitating with hydrochloric acid, and again extracting from the purified precipitate with ether, obtained a colorless crystalline principle, which he calls *santal*, $C_8H_8O_3 + \frac{1}{2}H_2O$.

Cazeneuve and Hugonng (*C. R. A. S.*, 104, 1722, 1725) have described two crystalline principles which they have extracted from red saunders, *pterocarpin*, $C_{20}H_{16}O_6$, and *homopterocarpin*, $C_{24}H_{24}O_6$, of which the former fuses at 152° C. and the latter at from 82° to 86° C. The wood has no medicinal virtues, and is employed solely for the purpose of imparting color.

SANTONICA. U. S.

SANTONICA [Levant Wormseed]

(san-tŏn'ī-cā)

"The dried unexpanded flower-heads of *Artemisia pauciflora* (Ledebour) Weber (Fam. Compositae)." *U. S.*

Turkestan, Aleppo, Alexandria or European Wormseed; Santonici Semen, Semen Cina, Flores Artemisia; Semen Sanctum; Semen-contra, Semenine ou Barbotine, *Fr. Cod.*; Flores Cinae, *P. G.*; Wurmsamen, Zitwersamen, *G.*; Santonico, *It.*, *Sp.*

Artemisia maritima, L., *Sp. Pl.* (1753) 846,¹ is a small, semi-shrubby perennial, from whose oblique, knotted rootstalks arise numerous leafy shoots and flowering stems. The glabrous and woody stems bear on their many branches numerous small (one inch long) bi- to multi-pinnatifid leaves, while the leaves of the flowering stems are very minute, the upper ones simple. The flower heads are small, numerous, one-tenth of an inch long, with from twelve to eighteen involucre scales, and from three to five flowers. The plant varies very greatly, and several species have been made out of its varieties. The form whose floral buds are said to resemble most closely the commercial drug has been named *A. cina* by Berg and Schmidt (t. 29, c.), and *A. pauciflora* by Weber (*Stechm. de Artem.*, 1775, 26). Following Bentley and Trimen, 157, the revisers of the *U. S. Pharm.* 1890 recognized the specific distinctness of the variety *pauciflora* and adopted the name given by Weber; but the propriety of this seems doubtful, since the researches of the Russian botanists Besser and Ledebour indicate that the forms are not specifically distinct, but are merely varieties of one plant, which has an extremely wide distribution in the northern hemisphere; from the old marshes of the British Islands it has spread along the coasts of the Baltic and the Mediterranean and eastward over the saline soils in Hungary, through Southern Russia and Central Siberia, to Chinese Mongolia. Nor do Engler and Prantl recognize the species *A. pauciflora*, Weber. They consider with Willkomm that the origin of wormseed is *A. cina*, Berg. (See also *P. J.*, 1872, 762.)

The British Pharmacopœia under the head of *Santoninum* refers the source to *A. maritima* var. *Stechmanniana*, Besser. In European commerce there are two kinds of wormseed, one called *Aleppo*, *Alexandria*, or *Levant wormseed*, the other *Barbary wormseed*. The *Barbary wormseed* is thought by some to be derived from *Artemisia judaica*, by others from *A. Sieberi*² of Besser (*A. glomerata* of Sieber), and from *A. ramosa*, C. Smith, all of which grow in Palestine and Arabia. It consists of broken peduncles, having the calyx sometimes attached to their extremity. The calyx is also sometimes separate, consisting of very small linear obtuse leaflets. The flowers are wanting, or are in the shape of minute globular buds. All these parts are covered with a whitish down, which serves to distinguish this variety from the wormseed of the Levant. It is, moreover, lighter and more colored than the latter. Its odor and taste are the same. The Levant wormseed is the *santonica* of the *U. S. Pharmacopœia*. It is

¹Heckel and Schlagdenhauffen (*C. R. A. S.*, 804) find that *Artemisia gallica* contains santolin, essential oil, and probably an alkaloid.

²*A. Sieberi* is in all probability, however, but a variety of the very variable *A. herba-alba*, which is used by the Arabs under the name of "*chili*" as a vermifuge, and in which Battandier found two resins and a large quantity of essential oil, but no santolin.

officially described as "heads 2 to 4 Mm. long, oblong-ovoid, slightly flattened, obtuse, consisting of an involucre of about 12 to 18 closely imbricated, glandular scales with broad mid-ribs, enclosing 4 to 5 rudimentary florets. Santonica has the appearance of a granular, yellowish-green or greenish-brown, somewhat glossy powder; odor strong, peculiar, somewhat camphoraceous; taste aromatic and bitter." U. S. Astolfi (*Ph. Ztg.*, 1893, 333) gives the following test for recognizing adulteration of santonica. 1 Gm. of the suspected drug is finely pulverized and then agitated with 10 Cc. of absolute alcohol; the whole is heated to boiling, filtered, a piece of potassium hydroxide is added to the filtrate, which is then heated. If the drug is pure, the liquid will acquire a pronounced red color; if falsified, the color will be yellow; and if no santonica be present, the liquid will be colored but faintly, if at all.¹

Most of the wormseed of commerce comes from the steppes of the northern portion of Turkestan to the great Nizhni-Novgorod fair, whence it finds its way to Moscow and Western Europe. The export from this region is said to have reached 1600 tons annually, but has largely declined, because the conquest of Turkestan by Russia led to the erection in Orenburg and Tschimkent of factories for the manufacture of santonin, which is now sent from there into commerce. The yearly consumption of santonin throughout the world is estimated at about twenty-five tons, and of this at least twelve tons are produced in the factories just spoken of. The santonin in the plants is said to reach its maximum proportion in July and August, and to disappear immediately after the flowering.

Wormseed contains a volatile oil, but it owes its efficiency to *santonin*. (See *Santoninum*.) According to Merck, the mother liquors in the manufacture of santonin from the seeds of *Artemisia maritima* yield a crystalline principle, $C_{15}H_{18}O_3$, which has been named *artemisin*. It is freed from santonin by recrystallization from chloroform. It melts at $200^{\circ} C$, gradually turns yellow in the air, and is more readily soluble in water and in dilute alcohol than is santonin. It gives a fugitive carmine red color when heated with aqueous or alcoholic sodium hydroxide, and is apparently a

hydroxy-santonin. (*P. J.*, 1896, 484.) *Dose*, of artemisin, 1-640th of a grain (0.0001 Gm.). The oil of santonica, according to Wallach (*Ann. Ch. Ph.*, 225, 314, and 227, 277), is mostly made up of *cineol*, $C_{10}H_{18}O$, which is isomeric with borneol, and seems to be identical with the cajuputol of cajuput oil, together with some *dipentene*. Wormseed is rarely used in this country in substance. It is stated that artemisin is a powerful stimulant to the mucous membrane and muscles of the alimentary canal and that its addition to the simple bitters greatly increases their activity.

Dose, of santonica, ten to thirty grains (0.65 to 2.0 Gm.).

SANTONIN

(săn-tō-nī'nŭm)

$C_{15}H_{18}O_3 = 244.29$

"The inner anhydride or lactone of santonie acid, obtained from Santonica. It should be kept in dark amber-colored vials and in a dark place." U. S. "A crystalline principle, $C_{15}H_{18}O_3$, prepared from santonica, the dried unexpanded flower-heads or capitula of *Artemisia maritima*, var. *Stechmanniana*, Besser." Br.

Santonine, Anhydride Santonique. *Fr. Cod.*; Santonium, *P. G.*; Santonin, *G.*; Santonina, *It., Sp.*

The present U. S. P. and the Br. Ph. 1898 very properly omit processes for the preparation of santonin. (See U. S. D., 17th ed., 1191.)

By the U. S. process of 1870, which was taken from Wittstein's *Pharmaceutical Chemistry*, the santonica is first exhausted by digestion with diluted alcohol, in connection with slaked lime,—the latter substance being employed to combine with the santonin and remove coloring matter which may subsequently embarrass the proceedings. The tincture thus obtained, having been reduced by the distillation of the alcohol to little more than an aqueous solution, is filtered and treated with acetic acid in slight excess, by which the santonin is separated from the lime which holds it in solution, and, being itself insoluble, is gradually deposited in a crystalline state. The remainder of the process is intended simply to obtain the crystals free from coloring matter, and otherwise pure.

The British (1885) process, which is that of Mialhe somewhat modified (*P. J.*, 1864, 635), spares the expenditure of alcohol in the exhaustion of the santonica, by boiling it originally with water in connection with lime, and differs also from the preceding in precipitating the santonin by hydrochloric instead of acetic acid. The purification is effected in the same manner, except that solution of ammonia is employed in the washing, probably to remove the last trace of acid. Wormseed of Aleppo yields from 1.2 to 1.4 per cent. of santonin. (*J. P. C.*, Mars, 1864, p. 241.) It has been

¹ For a method of valuing santonica, by Dragendorff, see *Proc. A. Ph. A.*, xxvi, 229.

Ehling's Process for valuing Santonica.—Five parts of santonica and one part of milk of lime were boiled for two hours in a considerable quantity of dilute alcohol and the liquid poured off after cooling; this treatment was repeated at least twice more, and the alcohol was then distilled off from the united extracts. The residual liquid was then saturated in the cold with carbonic acid, filtered off from the precipitate after standing some hours, and the filtrate evaporated to dryness. The residue was triturated with animal charcoal and alcohol of specific gravity 0.935, and the paste rinsed into a retort, where it was digested with a measured quantity of alcohol. After boiling, the contents of the retort were thrown on a filter, washed with hot alcohol, and the alcohol driven off from the filtrate, from which, after some hours, crystals of santonin separated. (*P. J.*, 1886, p. 449.)

intimated to us that the large manufacturers of santonin, abroad, first distil off from the santonica its volatile oil, which has some commercial value in Europe, and that the process for preparing santonin is probably facilitated thereby, the affinity of the oil for the santonin making the latter more difficult of purification.

Santonin has been lowered in price since the erection of a factory in Tschimkent, Turkestan, where the Levant wormseed can be furnished cheaply; the process used there is to treat the wormseed with milk of lime; the calcium santonate formed is next treated with sodium hydroxide and carbon dioxide; the sodium santonate is then decomposed by sulphuric acid. The acid liquid, on refrigeration, lets fall the santonin in crystals.

Properties.—Santonin is in "colorless, shining, flattened rhombic prisms; odorless, and nearly tasteless when first put into the mouth, but afterwards developing a bitter taste; permanent in the air, but turning yellow on exposure to light. It sublimes without decomposition, and is soluble in alkalies and in most volatile and fatty oils. Santonin which has become yellow may be converted into white crystals by recrystallization from alcohol. Soluble in 5300 parts of water, 34 parts of alcohol, 78 parts of ether, and in 2.5 parts of chloroform at 25° C. (77° F.); soluble in 800 parts of water at 80° C. (176° F.), and in 5 parts of alcohol at 60° C. (140° F.). It melts at 170.3° C. (338.5° F.). When ignited, it is consumed, leaving no residue. Its solutions are lævogyrate and neutral to litmus paper. If 0.5 Gm. of Santonin be heated with 5 Cc. of alcoholic potassium hydroxide T.S., a red color will be developed. Upon shaking 0.01 Gm. of Santonin with a cold mixture of 1 Cc. each of sulphuric acid and water, heating to 100° C. (212° F.), and adding a minute trace of very dilute solution of ferric chloride, a violet color will result. Sulphuric acid added to Santonin should not produce more than a faintly yellow color (absence of sugar and other readily carbonizable organic impurities). If 2 Gm. of Santonin be boiled with 80 Cc. of water and 5 Cc. of diluted sulphuric acid, and the liquid, after frequent shaking, be allowed to become cold and then filtered, mercuric potassium iodide T.S., or iodine T.S., should produce no cloudiness in 10 Cc. of the filtrate, mixed with 10 Cc. of distilled water, even after standing for three hours (absence of alkaloids)." U. S. "Colorless flat rhombic prisms, feebly bitter, fusible and volatile when gently heated. Scarcely soluble in cold and sparingly in boiling water; soluble in 4 parts of chloroform, in 40 parts of cold and in 3 parts of boiling alcohol (90 per cent.). Sunlight renders it yellow. Added to warm alcoholic solution of potassium hydroxide, it yields a violet-red color. It is not dissolved by diluted mineral acids. Heated to redness, with free access of air, it burns without leaving any residue (absence of mineral impurity)." Br. For a test

for santonin, see *Ph. Era*, 1898, 210. The air has no effect upon it, but it becomes yellow on exposure to sunlight. According to Sestini, the santonin is changed, through the influence of light, into formic acid, and an uncrystallizable substance, much more soluble in alcohol and ether than santonin itself, which he calls *photosantonin acid*, $C_{15}H_{22}O_5$, and a red resinous substance. If the santonin be in alcoholic solution, after several months of exposure to sunlight it is changed into the ethyl ether of photosantonin acid. In its relations to polarized light it is very strongly lævogyrate, and retains this property with acids, though losing it entirely when combined with salifiable bases. (Buignet, *J. P. C.*, Janv. 1862, p. 26.)

When warmed with alkalies, santonin is changed into monobasic *santoninic acid*, $C_{15}H_{20}O_4$, while concentrated baryta water changes it on prolonged boiling into the isomeric *santononic acid*. Schmidt (*J. P. C.*, 4e sér., iii. 394) disproved the previously accepted statement that santonin was a glucoside; but Hesse (*Ber. d. Chem. Ges.*, vi. 1280) found santonin to be the anhydride of *santoninic acid*, and prepared this acid by adding an excess of diluted hydrochloric acid to an aqueous solution of the sodium salt, and adding ether, from which the acid may be recovered by evaporation. When santononic acid is heated to 120° C. (248° F.), it is resolved into santonin and water. It has a strongly acid reaction, and decomposes sodium and calcium carbonate.¹ For a history with

¹ *Sodium santoninate* (*Sodii Santoninas*) was official in the *Pharmacopœia Germanica* of 1872, and was recognized in the U. S. P. 1880. It may be prepared by adding santonin to a hot solution of sodium hydroxide as long as it is dissolved; if the liquid is allowed to evaporate slowly, the crystals of sodium santoninate are obtained. It was officially described as in "colorless, transparent, tabular, rhombic crystals, slowly colored yellow by exposure to light, slightly efflorescent in dry air, odorless, having a mildly saline and somewhat bitter taste, and a slightly alkaline reaction. Soluble in 3 parts of water, and in 12 parts of alcohol at 15° C. (59° F.), in 0.5 part of boiling water, and in 3.4 parts of boiling alcohol. When heated to 100° C. (212° F.), until it ceases to lose weight, the salt loses 18 per cent. of its weight (water of crystallization). At a higher heat it chars and finally leaves an alkaline residue, which imparts an intense yellow color to a non-luminous flame. The aqueous solution, on the addition of hydrochloric acid, deposits a crystalline precipitate which is soluble in chloroform, and which yields, with alcoholic solution of potassa, a scarlet-red liquid gradually becoming colorless. A five-per-cent. aqueous solution of the salt should not be precipitated nor be rendered turbid by sodium carbonate test-solution (absence of alkaline earths), nor by picric or tannic acids (absence of alkaloids)." U. S. 1880. This salt was very properly dropped at the U. S. P. 1890 revision, because it is more easily absorbed than santonin in crystals, and therefore much more dangerous to the patient and much less destructive to intestinal worms. It must be remembered that serious poisoning from santonin has frequently occurred, notwithstanding its difficulty of absorption.

Santonin and Sodium Albuminate.—Pavesi prepares this as follows: 1 part of santonin, 4 parts of sodium bicarbonate, and 2 parts of dried soluble albumin are warmed with a sufficient quantity of water at 60° to 70° F. until all are dissolved, and then evaporated to dryness at a very gentle heat. The santonin and sodium albuminate forms brilliant white scales, soluble in water. The mineral acids precipitate santonin and albumin, with disengagement of carbon dioxide. The reasons for which Pavesi gives the preference to this combina-

a review of the chemical constituents and decomposition products of santonin see Y. B. P., 1901, 487. Santonin is now considered to be the inner anhydride or lactone of santonioic acid.

Cannizzaro and Carnelutti (*Ber. d. Chem. Ges.*, xvi. 2685) have shown that santonioic acid breaks up on high heating into *propionic acid*, $C_3H_5O_2$, and *dihydrodimethylnaphthol*, $C_{10}H_7(CH_3)_2.OH$, and distilled over zinc dust it gives a mixture of dimethylnaphthol, $C_{10}H_8(CH_3)_2.OH$, dimethylnaphthalene, $C_{10}H_8(C_2H_5)_2$, and propylene.² *Santonone*, $(C_{15}H_{17}O_2)_2$, a decomposition product of santonin, is made by gradually adding zinc dust to a hot solution of santonin in acetic acid, preferably in the presence of a little platinum tetrachloride. It forms silky white needles, is very soluble in benzene, less so in hot alcohol, ether, or diluted acetic acid, and insoluble in water.

Uses.—Santonin has been used by oculists as a stimulant to the optic nerve in tobacco amaurosis and other forms of *amaurosis*; it is strongly commended in *amenorrhœa* by Bergy, but is chiefly used as a vermicide against the *lumbricoid worm*. In overdose it produces a poisoning whose symptoms are giddiness, mental apathy or stupor, great paleness and coldness of the surface, vomiting, profuse sweating, trembling, mydriasis, and finally loss of consciousness, with convulsions, often violent and accompanied by opisthotonos and emprostotonos and failure of respiration. Xanthopsia is an early and characteristic symptom. All objects appear discolored, generally yellow, but frequently green, and sometimes blue. At the same time the urine is tinged of a yellow or a green color, and so rapidly does the san-

tonin pass, that the change of color in the urine has been observed at the end of 16 minutes.¹ (*J. P. C.*, Août, 1863, p. 161.) These effects were formerly thought to be due to the staining of the aqueous humor but are more probably to be attributed to a direct action on the retina. In regard to the minimum fatal dose, two grains are said to have killed a feeble child five years old, and one six or seven years old is said to have suffered death from six grains after development of hæmaturia (*B. G. T.*, lxxiv. 362); four grains produced very serious symptoms in a child four years old. (*P. J.*, ix. 696.) The xanthopsia and discolored urine make the diagnosis of santonin poisoning easy. According to Crouzel the addition of alkalies to the urine will demonstrate the presence of santonin, before the coloration is pronounced, by the development of a characteristic carmine-red tint.

The santoninates are inferior to santonin, being more soluble, and for the same reason the principle is preferable in its natural crystalline form to the powder. Santonin is best administered in the form of lozenges made with sugar and tragacanth (for formula, see *A. J. P.*, vi. 124), which, if the unbroken crystals are used, can be rendered very pleasant to the taste, so that children will eat them as candy. The dose of santonin for a child two years old is from one-fourth to one-half grain (0.016 to 0.032 Gm.).

Dose, two to four grains (0.13 to 0.26 Gm.).

SAPU. U. S. (Br.)

SOAP [White Castile Soap]

(sā'pō)

"Soap prepared from sodium hydroxide and olive oil." *U. S.* "Soap made with sodium hydroxide and olive oil; containing about 30 per cent. of water." *Br.*

Sapo Durus, *Br.*; Hard Soap, Castile Soap; Savon medicinal, *Fr.* *Cod.*; Savon amygdalin, Savon blanc, Savon d'Espagne, *Fr.*; Sapo medicatus, *P. G.*; Medizinische Seife, Oel-Sodaseife, Seife, Spanische Seife, *G.*; Sapone medicinale, S. amigdalinu, Sapone duro, *It.*; Jabon de aceite de olivas, Jabon, *Sp.*

Soaps embrace all those compounds which result from the reaction of salifiable bases with fats and oils. Fats and oils, as has been explained under the titles *Adeps* and *Olea*, consist generally of three glyceryl esters, two solid, differing in fusibility, called *stearin* and *palmitin*, and one liquid, called *olein*. Stearin is found most abundantly in fats which are firm and solid, as suet and tallow, and palmitin and olein in the oils. When the fats and oils undergo *saponification* by reaction with a salifiable

tion over the use of santonin alone are the following. The after-effects of santonin, among others, that of yellowness of vision, are entirely obviated; the preparation is not decomposed in the stomach, because the sodium bicarbonate in the combination retains the santonin in solution, the coagulation of the albumin is prevented, gently purgative sodium salts are introduced into the body, and finally, by the disengagement of a small quantity of carbon dioxide, an active digestion is produced. It is not at all probable that these assertions are correct, but more extended research is justifiable.

²The physiological and medicinal properties of various derivatives of santonin have been studied by F. Coppola and by Cannizzaro. Of the more important of these derivatives, *photosantonioic acid* and *photosantonin* are said to be narcotics; while *isophotosantonin* and *isophotosantonioic acid* are not hypnotics, but convulsants. It is asserted that *santonioic acid* is fully as efficacious as santonin as a germicide, but is much less poisonous to the higher animals than santonin, being absorbed and eliminated very slowly as santonin. It is insoluble in water, easily soluble in oils and fats, but not in organic acids, and is not acted upon by the gastric juice. P. Gucci prepares santoninoxime as follows. Boil a mixture of five parts of santonin, four parts of hydroxylamine hydrochloride, fifty parts of alcohol, and three to four parts of calcium carbonate for six to seven hours on a water-bath, and add an excess of boiling water to the clear solution. The yield is 80 per cent. of the santonin employed. It crystallizes from alcohol in white, lustrous needles which melt at 218° to 219° C., and dissolves readily in alcohol and ether but very sparingly in boiling water. In hot solutions of alkaline hydroxides and carbonates it dissolves, being precipitated unchanged on the addition of an acid. On being warmed with very dilute hydrochloric acid, the santonin is quantitatively reproduced. It is lævo-rotatory. It can be borne in two or three times larger doses than santonin. (*Gazz. Chim. Ital.*, xix. 367 to 382.)

¹According to Walter G. Smith, the yellow color imparted to urine by santonin is distinguished from that produced by other substances by becoming purplish red on the addition of ammonia or other alkali. (*P. J.*, Dec. 1870, p. 528.) For researches upon the character of the urinary coloring matter, consult the same paper.

base, these three esters are decomposed into fatty acids peculiar to each, discovered by Chevreul, and called stearic, palmitic, and oleic acids, which unite with the base to form the soap, and into a sweet basic principle called glycerin (glycerol), which is set free. Hence it follows that stearin is a stearate of glyceryl, C_8H_5 , the radical of the triatomic alcohol glycerol, $C_3H_5(OH)_3$, palmitin a palmitate, and olein an oleate, and that the fats and oils are mixtures of these three fatty salts. Hence, also, it is obvious that soaps are mixed stearates, palmitates, and oleates of certain bases.

Stearic acid, $C_{18}H_{36}O_2$, is a firm white solid, like wax, fusible at $69.2^\circ C.$ ($157^\circ F.$), greasy to the touch, pulverizable, soluble in alcohol, very soluble in ether, but insoluble in water. In the impure state it is used as a substitute for wax in making wax candles. *Palmitic acid*, $C_{16}H_{32}O_2$, forms a white scaly mass, and melts at $62^\circ C.$ ($143.6^\circ F.$). *Oleic acid*, $C_{18}H_{34}O_2$, is an oily liquid, insoluble in water, soluble in alcohol and ether, lighter than water, crystallizable in needles, a little below $0^\circ C.$ ($32^\circ F.$), and having a slight odor and a pungent taste. (See *Acidum Oleicum*.) *Glycerin* is described under a separate head. (See *Glycerinum*.)

Soaps are divided into the soluble and the insoluble. The soluble soaps are combinations of the fatty acids with sodium, potassium or ammonium hydroxides; the insoluble consist of the same acids united with earths and metallic oxides. It is the soluble soaps only that are detergent, and to which the name *soap* is usually applied. Several of the insoluble soaps are employed in pharmacy, as, for example, the lead monoxide soap, or lead plaster, and the lime soap, or lime liniment. (See *Emplastrum Plumbi* and *Linimentum Calcis*.) The two official soaps are of the soluble kind. One is a soda soap, made with olive oil (Castile soap), the other a potassium soap (soft soap). (See *Sapo Mollis*.) The soap of ammonia is noticed elsewhere. (See *Linimentum Ammoniac*.)

The consistence of the fixed alkaline soaps depends partly on the nature of the oil or fat, and partly on the alkali present. Soaps are harder the more stearate and palmitate they contain, and softer when the oleate predominates, and, as respects the alkali present, they are harder when formed with sodium hydroxide, and softer when containing potassium hydroxide. Hence it is that of pure soaps, considered as salts, sodium stearate is the hardest and least soluble, and potassium oleate the softest and most soluble.

Preparation.—The following is an outline of the process for making soap. The oil or fat is boiled with a solution of caustic alkali, beginning with a weak solution, and as saponification proceeds using a stronger lye until the whole forms a thick mass, which can be drawn out into long clear threads. After the soap is completely formed, the next step is to sepa-

rate it from the excess of alkali, the glycerin, and the redundant water. This is effected by adding common salt, or a very strong alkaline lye, in either of which the soap is insoluble. The same end may be attained by boiling down the solution until the excess of the alkali forms a strong alkaline solution, which acts the same part in separating the soap as the addition of a similar solution. As soon as the soap is completely separated, it rises to the surface, and, when it has ceased to froth in boiling, it is ladled out into wooden frames to congeal, after which it is cut into bars by means of a wire. The soap, as first separated, is called *grain soap*. It may be purified by dissolving it in an alkaline lye and separating it by common salt. During this process the impurities subside, and the soap combines with more water, and hence it becomes weaker, although purer and whiter. If the grain soap be not purified, it will form *marbled soap*,—the colored streaks arising principally from an insoluble soap of oxidized iron. Sometimes the marbled appearance is produced by adding to the soap, as soon as it is completely separated, a fresh portion of lye, and immediately afterwards a solution of ferrous sulphate. The greenish-black ferrous hydroxide is precipitated, and gives rise to dark-colored streaks, which, by exposure to the air, become red in consequence of the conversion of the black hydroxide into the ferric hydroxide.

When commercial toilet soap is required, the *grained soap*, or, as it is sometimes called, *boiled soap*, is often remelted, perfumed, and worked over by the process of *milling*, *plotting*, and *moulding*, whereby the soap is brought into the desired shape for popular use. The *cold process* is also used, and is preferred by many because of its simplicity and economy. The following (from Sadtler's *Industrial Organic Chemistry*, 1906, 64) gives the outlines of the process. The so-called "cold process" requires the use of exact weights of well-refined fats and of caustic soda of a given specific gravity (from 32° to $36^\circ B.$), the quantities being such that only just enough soda is present to completely saponify the fat. The materials are allowed to stand together for a short time and then thoroughly mixed in a copper provided with steam agitating paddles, and kept at a temperature of not over $120^\circ F.$ The reaction proceeds rapidly, and after some fifteen minutes the materials have so far united that they will not separate on standing, although the complete saponification of the charge may require days. They are then run out into the cooling frames. It is obvious that soaps made in this way retain all the glycerin originally combined with the fatty acids disseminated through the particles of soap, and belong to the class of "filled" or "padded" soaps. When coconut oil alone is used, the temperature of working in this cold process need not be higher than $75^\circ F.$ in summer and $90^\circ F.$ in winter; if one-half tallow, from 104°

to 108° F., and if two-thirds tallow, from 113° to 120° F. is necessary. A well-refined tallow can be saponified in this way, too, and rosin may be added.¹

¹The following very practical process is by W. J. Menzies (C. D., Aug. 1880):

On the Manufacture of Soap in small Quantities without Boiling.—Take exactly 10 lbs. of double-refined 98 per cent. powdered sodium hydroxide (Greenbank), put it in any can or jar with 45 lbs. (4½ gallons) of water, stir it once or twice, when it will dissolve immediately and become quite hot; let it stand until the lye thus made is cold. Weigh out, and place in any convenient vessel for mixing, exactly 75 lbs. of clean grease, tallow, or oil (not mineral oil). If grease or tallow be used, melt it slowly over the fire until it is liquid and just warm,—say temperature not over 37.7° C. (100° F.). If oil is used, no heating is required. Pour the lye slowly into the melted grease or oil in a small stream continuously, at the same time stirring with a flat wooden stirrer about three inches broad; continue gently stirring until the lye and grease are thoroughly combined and in appearance like honey. Do not stir too long, or the mixture will separate itself again. The time required varies somewhat with the weather and the kind of tallow, grease, or oil used; from 15 to 20 minutes will be enough. When the mixing is completed, pour off the liquid soap into any old square box for a mould sufficiently large to hold it, previously dampening the sides with water so as to prevent the soap sticking. Wrap up the box well with old blankets, or, better still, put it in a warm place until the next day, when the box will contain a block of 130 lbs. of soap, which can afterwards be cut up with a wire. Remember the chief points in the above directions, which must be exactly followed. The lye must be allowed to cool. If melted tallow or grease be used, it must not be more than warm. The exact weights of double-refined 98 per cent. powdered sodium hydroxide and tallow or oil must be taken; also the lye must be stirred into the grease, not the grease or oil added to the lye. If the grease or tallow used be not clean, or contain salt, it must be "rendered," or purified, previous to use, that is to say, boiled with water, and allowed to become hard again to throw out the impurities. Any salt present will spoil the whole operation entirely, but discolored or rancid grease or tallow is just as good as fresh for soap making purposes.

If the soap turn out streaky and uneven, it has not been thoroughly mixed. If very sharp to the taste, too much sodium hydroxide has been taken. If soft, mild, and greasy, too little soda has been used. In either case it must now be thrown into a pan and brought to a boil with a little more water. In the first case boiling is all that is necessary; in the other instances a very little oil or a very little more of the double refined powdered sodium hydroxide must be added to the water. These things will never happen, however, if the directions be exactly followed, and after the soap has been made several times with the experience thus gained the process is extremely easy. Beef tallow makes the hardest soap, mutton fat a rather softer soap; of oils, cotton-seed is the cheapest and best, but the soap is much softer, lathering very freely indeed. Ordinary household fat or drippings will make a nice soap, and in many places can be obtained at a very trifling cost and in exchange for goods sold. Such grease, however, must be carefully examined for salt, which it often contains. It will be evident that any smaller quantity of soap can be made at a time, according to the above directions, by taking the ingredients in exact proportion. It is not advisable to make more than double the quantity prescribed, as it is difficult to work more by hand. By making successive batches, however, a single person can make two tons of soap in a day simply with apparatus (pans, etc.) obtainable in any household.

By adding a few drops of essential oil just when the mixing is completed, a toilet soap is produced. Oil of mirbane (artificial almond oil) is the cheapest, but the perfume is not nearly so pleasant as real almond oil, citronella, or oil of cloves. If made with clean grease or tallow or light-colored oil, the soap produced is quite white.

Sometimes a little coloring matter will make soap sell better, although of no better quality. Half an ounce of potassium dichromate dissolved in the lye will give a green color; 1 lb. of palm oil melted

The official soap (*Sapo*, U. S.; *Sapo Durus*, Br.) is an olive oil soda soap, made on the same general plan as that just explained.

Common soap is also a soda soap; but instead of olive oil it contains solid animal fats. This soap corresponds with the white soap of northern European countries and of the United States, and is formed usually from barilla and tallow. In Scotland it is manufactured from kelp and tallow. It was introduced into the U. S. Pharmacopœia of 1860 as the only proper soap for making opodeldœ; but, as this preparation was discarded, this variety of soap was dismissed along with it.

Besides the official soaps of the U. S. and Br. Pharmacopœias, there are many other varieties, more or less used for medicinal or economical purposes. The official soap of the French Codex (1837), called *amygdaline soap* (almond oil soap), is formed of sodium hydroxide and almond oil, and is directed to be kept for two months exposed to the air before being used. *Starkey's soap*, also official in the Codex, is prepared by uniting, by trituration, equal parts of potassium carbonate, oil of turpentine, and Venice turpentine. *Beef's marrow soap* is a fine animal oil soap, also included in the French standard of pharmacy. *Windsor soap* is a scented soda soap, made of one part of olive oil and nine parts of tallow. *Eau de luce* (*aqua lucis*) is a kind of liquid soap, formed by mixing a tincture of oil of amber and balsam of Gilead with ammonia water. *Transparent soap* is prepared by saponifying kidney fat with soda free from foreign salts, drying the resulting soap, dissolving it in alcohol, filtering and evaporating the solution, and running it into moulds when sufficiently concentrated. The soap is yellow or yellowish brown, and preserves its transparency after desiccation. Harding (*Proc. Minn. Pharm. Assoc.*, 1896, 116) states that sugar is used in soap to give it transparency and sodium carbonate to give firmness. The German transparent soap always contains a large quantity of cocoanut-oil soap. *Palm soap* is prepared from sodium hydroxide and palm oil, to which tallow is added to increase its

with the tallow or oil, a yellow color; or a good brown can be secured by burning ½ lb. of sugar in a saucepan until black, then dissolving it in a pint of water, and adding it to the melted tallow before mixing.

A very cheap and good jelly soft soap can be made with soap. Take 5 lbs. of the hard soap, crush it down or cut it up into as small pieces as possible; put this into a pan or boiler with 10 gallons of water if a strong hard tallow soap; if an oil soap, only half the quantity of water (5 gallons); just bring it to a boil, and stir well, to thoroughly dissolve all the pieces of hard soap; pour or ladle it into any can, tub, or barrel that is tight, and leave it to cool for two or three days. This will give about 80 lbs. of jelly soft soap at an exceedingly small cost. Of course, if made from colored and scented hard soap it will be a colored and scented jelly soap. This is a good way of working up the scraps and bits of soap after cutting up. It is a very different article, however, from a real potash soap, which should invariably be used for washing woollens. It is possible to produce this real potash soft soap in the cold by a process somewhat similar to the above.

firmness. If it be wanted white, the palm oil may be bleached by heat, potassium dichromate with sulphuric acid, chlorine, or exposure to the sun. This soap has a yellowish color, and the agreeable odor of violets derived from the oil. *Soap balls* are prepared by dissolving soap in a little water and then forming it with starch into a mass of the proper consistence. *Common yellow soap* (*rosin soap*) derives its peculiarities from an admixture of rosin and a little palm oil with the tallow employed, the oil being added to improve its color. Sodium silicate has to some extent been substituted for rosin, as more economical. (*A. J. P.*, 1863, p. 466.) Large quantities of lard oil (nearly pure olein) are manufactured into soap.¹

All the varieties of soap, except a few of the fancy sort and the olive oil soaps, are manufactured in the United States. The latter are mainly imported from France, Italy, and Spain.

Properties.—Soap, whatever may be its variety, has the same general properties. Its aspect and consistence are familiar to every one. Its odor is peculiar, and its taste slightly alkaline. It is usually somewhat heavier than water, and therefore sinks in that liquid. Exposed to heat it quickly fuses, swells up, and is decomposed. It is soluble in water, and more readily in hot than in cold. Potassa soaps and those containing oleic acid are far more soluble than the soda soaps, especially those in which the stearates and palmitates predominate. Acids added to an aqueous solution of soap combine with the alkali, and set free the oily acids, which, being diffused through the water, give it a milky appearance. Its decomposition is also produced by metallic salts, which invariably give rise to insoluble soaps. Soap is soluble in cold and abundantly in boiling alcohol. This solution constitutes the *tincture of soap*, and forms a very convenient test for discovering lime in natural waters. As the tincture sometimes gelatinizes, it is proposed by Bjorklund to remedy this inconvenience by employing soap in the undried state, that is, containing a large proportion of water. (*J. P. C.*, 4e sér., ii. 179, 1865.) The efficacy of soap as a detergent depends upon its hydrolytic decomposition when in solution, whereby alkali is liberated which saponifies and emulsifies grease and fatty substances rendering them readily removable in the washing processes. The chief adulterations in soap are lime, silica, gypsum, heavy spar, steatite, pipe-clay, and sodium sulphate. When adulterated with these substances, it will not be entirely soluble in alcohol. According to Riegel, glue is

an occasional adulteration in Spanish soap, discoverable also by its insolubility in alcohol. The same impurity is sometimes found in other soaps. Soap is officially described as “a white or whitish solid, hard, yet easily cut when fresh, having a faint, peculiar odor free from rancidity, a disagreeable, alkaline taste, and an alkaline reaction. Soluble in water and in alcohol, more readily with the aid of heat. On placing 0.5 Gm. of Soap, together with about 10 Cc. of alcohol, in a tared beaker containing 1 Gm. of dry, clean sand, evaporating the resulting solution of the Soap to dryness, and drying the residue at 110° C. (230° F.), to a constant weight, the loss should not exceed 36 percent. (absence of an undue amount of water). An alcoholic solution of Soap (1 in 25) should not gelatinize on cooling (absence of animal fats). An aqueous solution of Soap 1 in 20) should remain unchanged in color upon the addition of ammonium sulphide T.S.; and upon acidulating another portion of the solution with hydrochloric acid and filtering, the filtrate should remain unchanged in color when an equal volume of hydrogen sulphide T.S. is added and the mixture is allowed to stand well stoppered in a warm place for half an hour (absence of metallic impurities). On dissolving 20 Gm. of Soap in alcohol, with the aid of heat, transferring the undissolved residue, if any, to a tared filter, and washing it thoroughly with boiling alcohol, it should, after drying, weigh not more than 0.8 Gm. (limit of sodium carbonate, etc.); of this residue not more than 0.2 Gm. should be insoluble in water (limit of silica and other accidental impurities). If a solution of 5 Gm. of Soap in 50 Cc. of hot water be mixed with 3 Cc. of tenth-normal oxalic acid V.S., the subsequent addition of a few drops of phenolphthalein T.S. should produce no pink or red tint (limit of alkalinity).” *U. S.* “Grayish-white, dry, inodorous; becomes horny and pulverizable when kept in dry warm air. Easily moulded when heated. Soluble in alcohol (90 per cent.), especially on warming. Soluble in 20 parts of cold water, and in 1½ parts of hot water. It should not contain more alkaline hydroxide or carbonate than is allowed under ‘Sapo Animalis.’ It does not impart a greasy stain to white unglazed paper (absence of free oil). Incinerated it yields an ash which does not deliquesce (absence of potassium soap). It should lose about 30 per cent. of moisture when dried at 230° F. (110° C.)” *Br.*

Olive oil soda soap (*Sapo*), otherwise called *Castile* or *Spanish soap*, is a hard soap, and is presented under two principal varieties, the white and the marbled. *White Castile soap*, when good, is of a pale grayish-white color, incapable of giving an oily stain to paper, devoid of rancid odor or strong alkaline qualities, and entirely soluble both in water and in alcohol. It should not feel greasy, nor grow moist, but, on the contrary, should become

¹ Upon the supposition that the detergent properties of soap depend exclusively on the alkali it contains, and are consequently proportionate to the quantity of that ingredient, a mode of estimating the relative value of soaps has been suggested by R. Graeger, based on the molecular weight of the fatty constituent,—those soaps being the strongest of which the acid has the lowest combining number. (*See A. J. P.*, 1861, p. 355.)

dry by exposure to the air, without exhibiting any saline efflorescence. This variety of soap contains about 21 per cent. of water. Sometimes it contains a larger proportion of water, with which the soap is made to combine by the manufacturer, with the fraudulent intention of increasing its weight. Soap thus adulterated is known by its unusual whiteness, and by its suffering a great loss of weight in a dry air. The proportion of water may be ascertained by introducing the soap into a saturated solution of sodium chloride, and boiling, when the soap, nearly free from water, concretes into a solid mass. *Marbled Castile soap* is harder, more alkaline, and more constant in its composition than the other variety. It contains about 14 per cent. of water. Having less water than the white Castile, it is a stronger and more economical soap, but at the same time is less pure. The impurity arises from the veins of marbling, consisting of ferruginous matters, as already explained, and from various substances added as make-weights. Soap made with animal fat, with the probable addition of sodium silicate, has been sold for Castile soap. The Italian brands of Castile soap which have been so largely used in past years are rapidly depreciating in quality; they are now chiefly made from cotton seed oil and other substitutes for olive oil.

Animal oil soda soap (*Sapo Vulgaris*) is a hard soap, of a white color, inclining to yellow. It is made from tallow and sodium hydroxide. This soap possesses the same general properties as the olive oil soda soap.

Composition.—It has been already explained that soap consists of certain fatty acids united with an alkali. As olive oil is a compound of olein with palmitin and small quantities of the esters of other fatty acids, so the official "soap" is a mixed sodium oleate and palmitate. The former official "common soap" is principally a sodium stearate, and "soft soap," as defined in the Br. Pharmacopœia, is a mixed potassium palmitate and oleate. The table below, from Roscoe & Schorlemmer, gives an excellent view of the composition of commercial soap.¹

Incompatibles.—Soap is decomposed by all the acids, earths, and earthy and metallic salts. Acids combine with the alkali, and set free

the fatty acids of the soap; the earths unite with the fatty acids, and separate the alkali, while the earthy and metallic salts give rise, by double decomposition, to an insoluble soap of their base, and a saline combination between their acid and the alkali of the soap. Hard waters, in consequence of their containing salts of lime, decompose and curdle soap. They may be rendered soft, and fit for washing, by adding sufficient sodium or potassium carbonate to precipitate all the lime.

Uses.—Soap possesses the properties of a laxative, antacid, and antilithic. It acts like an alkaline base and was formerly used to some extent internally, but has been entirely superseded by more elegant alkaline compounds, except in laxative preparations, especially in combination with rhubarb. In *constipation* of the bowels, particularly when arising from hardened fæces in the rectum, a strong solution of soap, especially of soft soap, forms a useful enema. When the latter is used, two tablespoonfuls may be dissolved in a pint of warm water. In pharmacy, soap is frequently employed for the purpose of giving a proper consistence to pills; but care must be taken not to associate it with a substance which may be decomposed by it. It is also an ingredient in some liniments and plasters. In toxicology it is used as a chemical antidote for the mineral acids, and should always be resorted to in poisoning by these agents, without a moment's delay, and its use continued until magnesia, chalk, or sodium or potassium bicarbonate can be obtained. The mode of administration in these cases, is to give a teacupful of a strong solution of soap every three or four minutes, until the patient has taken as much as he can swallow.

Dose, five grains to half a drachm (0.32 to 2.0 Gm.), given in pill.

SAPO ANIMALIS. Br.

CURD SOAP

(sā'pō ān-j-mā'lis)

"Soap made with sodium hydroxide and a purified animal fat consisting principally of stearin; containing about 30 per cent. of water." *Br.*

Sapo Sebacinus; Sapo domesticus; Animal Soap, Tallow Soap, Stearin Soap; Savon animal, *Fr. Cod.*; Hausseife, Talgseife, Stearinseife, *G.*; Sapone animale, *It.*; Jabon animal, *Sp.*

The British Pharmacopœia 1898 has retained curd soap in its list, and thus describes it: "White or with a very light grayish tint; dry; nearly inodorous; becomes horny and pulverizable when kept in dry warm air. Easily moulded when heated. Soluble in alcohol (90 per cent.), especially on warming. Sparingly soluble in cold water; soluble in hot water. 5 grammes of the dried and powdered soap, digested in boiling alcohol (90 per cent.), filtered while hot, and the filter washed thoroughly with more of the boiling alcohol, yield a filtrate which should not afford a red or pink coloration with solution of phenolphthalein (limit of alkaline hydroxide); and the filter, when washed with hot water, will yield a solution which, on adding solution of phenolphthalein, should not require more than 3 cubic centimetres of decinormal volumetric solution of sulphuric acid to discharge the resulting red color (limit of alkaline carbonate). It does not impart a greasy stain to white unglazed paper (absence of free oil and fat). Incinerated it yields an ash which does not deliquesce (absence of potassium soap). It should lose about 30 per cent. of moisture when dried at 230° F. (110° C.)." *Br.*

Soap made from animal oils and fats is very largely used for all domestic purposes; it is preferred pharmaceutically for making *solid opodeldoc* because of its partial insolubility in the hydro-alcoholic solvent. (See p. 1088.)

SAPO MOLLIS. U. S., Br.

SOFT SOAP [Green Soap]

(sā'pō mōl-lis)

"Soap made with potassium hydroxide and olive oil." *Br.*

Sapo Viridis, U. S. P. 1880; Savon mou, Savon vert, Savon à Base de Potasse, *Fr.*; Sapo Kalinus, *P. G.*; Kaliseife, Schmierseife, *G.*; Sapone di potassa, *It.*

* "Linseed Oil, four hundred grammes [or 14 ounces av., 48 grains]; Potassium Hydroxide, ninety-five grammes [or 3 ounces av., 154 grains]; Alcohol, forty cubic centimeters [or 1 fluidounce, 169 minims]; Water, a sufficient quantity. Heat the Linseed Oil in a

deep, capacious vessel, on a water-bath or steam-bath, to a temperature of about 70° C. (158° F.). Dissolve the Potassium Hydroxide in four hundred and fifty cubic centimeters [or 15 fluidounces, 104 minims] of Water, warm the solution to about 70° C. (158° F.), add it to the Linseed Oil, and mix thoroughly; then incorporate the Alcohol and continue the heat (without stirring) until a small portion of the mixture is found to be soluble in boiling Water without the separation of oily drops. Then allow the mixture to cool, and transfer it to suitable vessels. The Potassium Hydroxide used in this process should be of the full strength directed by the Pharmacopœia (85 percent.). Potassium Hydroxide of any other strength, however, may be used, if a proportionately larger or smaller quantity be taken, the proper amount for the above formula being ascertained by dividing 8075 by the percentage of absolute Potassium Hydroxide contained therein." *U. S.* The above process was first introduced into the U. S. P. 1890 with the view of affording a soft soap for medicinal purposes which shall be of uniform strength. Domestic soft soap is prepared on the same general principles as hard soap, potassium hydroxide being employed as the alkali, and a fatty matter, rich in olein, as the oil. The French soft soap is made with the seed oils, such as rape seed, hemp seed, etc.; the Scotch and Irish, with fish oil and some tallow, and our own, with refuse fat and grease. A lye of wood ashes is the form of potassium usually employed. In forming this soap it is necessary that it should continue dissolved in the alkaline solution, instead of being separated from it. Hence soft soap is a potassium soap completely dissolved in the solution of its alkali, which is present in excess. As made in this country, it is usually semi-fluid, slippery, capable of being poured from one vessel to another, and of a dirty brownish-yellow color and varying strength.

Properties.—It is officially described as "a soft, unctuous, yellowish-brown mass, having a characteristic odor and an alkaline taste. An aqueous solution shows an alkaline reaction to red litmus paper. If to a solution of 5 Gm. of Soft Soap in 50 Cc. of water, 2 drops of phenolphthalein T.S. be added, not less than 2.3 Cc. nor more than 4.5 Cc. of tenth-normal oxalic acid V.S. should be required to discharge the red tint (limit of free alkali). Soluble in hot water to a nearly clear liquid; also in hot alcohol without leaving more than 3 percent. of insoluble residue." *U. S.* "Yellowish-white, sometimes yellowish-green, almost inodorous, of an unctuous consistence. Readily soluble in alcohol (90 per cent.), especially on warming, the liquid, on filtration, yielding not more than 3 per cent. of residue (limit of potassium carbonate, insoluble soaps, etc.). It should not contain more alkaline hydroxide or carbonate than is allowed under 'Sapo Animalis.' It does not impart an oily stain to paper (ab-

sence of free oil). Incinerated it yields an ash which is very deliquescent, and which should afford no reaction with the tests for copper." *Br.*

For more than one hundred years, under the name of "green soap," there has been used in Europe a soap made by saponifying linseed, rape seed, or other vegetable oils with various refuse oils, usually including fish oils, an excess of potassium hydroxide, and a little sodium hydroxide. The green color of this soap was probably due to the presence of chlorophyll in the impure vegetable oils used. This green soap, or so-called "German soap," was formerly imported into America, but at present has been almost entirely superseded by soft soap made in this country, from which it does not differ in the nature of its active constituents or in its therapeutic properties.

If a green soap be wanted, it may be made by the process given in the foot-note.¹ The soft soap of France, formerly the *savon vert* of the French Codex, has a greenish color and usually the consistence of a soft ointment. It is made of hemp seed oil, or sometimes of the dregs of olive oil, and potassium hydroxide. G. M. Beringer (*Proc. A. Ph. A.*, 1903, 420) prefers to use Malaga olive oil in making green soap and M. I. Wilbert (*Proc. A. Ph. A.*, 1904, 228) extracts the green coloring matter from hemp seed by macerating 25 parts of ground hemp seed with alcohol and obtains 100 parts of a tincture; by substituting an equal measure of this tincture for the quantity of alcohol used in the official process, a green soap can be made, which will have the color which is regarded by some as a very important characteristic.

Uses.—Soft soap is used in medicine almost exclusively in the treatment of *eczema rubrum*, although sometimes used in other diseases of the skin in which a very powerfully stimulant application is desired. It acts chiefly by virtue of the excess of potassium hydroxide, which enables it to destroy fatty matters rapidly, to remove exudation, and to affect the nutrition of the skin. The tincture, the form in which it is usually employed, may be well rubbed upon the part, either in full strength or diluted, and

immediately afterwards the skin must be well washed to remove the alkali, and then zinc oxide or other bland ointment applied.

SARSAPARILLA. *U. S. (Br.)*

SARSAPARILLA

(sär-sä-pä-ril'lä)

"The dried root of *Smilax medica* Chamisso and Schlechtendal, *Smilax ornata* Hooker, *Smilax papyracea* Duhamel, or a dried root known commercially as Honduras Sarsaparilla, which is probably obtained from *Smilax officinalis* Kunth (Fam. *Liliaceæ*)." *U. S.* "The dried root of *Smilax ornata*, Hook. f. Imported from Costa Rica and commonly known as Jamaica sarsaparilla." *Br.*

Sarsæ Radix, Br.; Jamaica Sarsaparilla; Salsepareille, *Fr. Cod.*; Radix Sarsaparillæ, *P. G.*; Sarsaparille, Sarsaparilla, *G.*; Salsapariglia, *It.*; Zarzaparrilla (Raiz de), *Sp.*

In the present state of our knowledge, it is impossible to decide with positiveness from what species the several commercial varieties of the drug are respectively derived. The matter is made more difficult by the observation of H. H. Rusby that the sarsaparilla which was undoubtedly grown in Honduras and which was believed by Rusby to be derived from *S. ornata* or possibly a distinct species, could not be differentiated from true Jamaica sarsaparilla. (*D. C.*, Nov. 1903.) The root (rhizome) of *Smilax China*, a native of China and Japan, has been employed under the name of *China Root* for similar purposes with the official sarsaparilla. As it occurs in commerce, it is in pieces from three to eight inches long and an inch or two thick, usually somewhat flattened, more or less knotty, often branched, of a brownish or grayish-brown color externally, whitish or of a light flesh-color internally, without odor, and of a taste flat at first, but afterwards very slightly bitterish and somewhat acrid, like that of sarsaparilla. The root of *Smilax aspera* is said to be employed in the south of Europe as a substitute for sarsaparilla; but it has little reputation. The East India sarsaparilla, which was at one time referred to this species of smilax, is the product of *Hemidesmus indicus*.² (See *Hemidesmus*.) All the species of smilax are climbing or trailing plants, with prickly stems,—a character expressed in the name of the medicine, which is derived from two Spanish words (*zarzaparrilla*), signifying a small thorny vine.

The official species of smilax are as follows: *S. officinalis*, H. B. K., *Nov. Gen. et Sp.* (1815), 271.—In this species the stem is twin-

¹ "German Soft Soap."—E. B. Shuttleworth has furnished the following process for its preparation. "In a clean pot or dish, preferably of iron or copper, and capable of containing at least three times the quantity, put one part by weight of linseed oil; heat gently, and add, in two portions, three parts in all, by measure, of liquor potassæ, *U. S. P.* or *B. P.*, providing either come up to the standard requiring 5.8 and 5.84 per cent. of potassium hydrate. Boil quietly and stir frequently until the mass becomes clear, which with four ounces of oil and twelve ounces (fluid) of liquor will require about one hour, and with ten pounds of oil about five hours. If, during the process, the mass becomes too thick to stir easily, add a little water. Allow the soap to become cool, but, before it sets, work in the coloring matter, which must be previously prepared by boiling finely-powdered indigo with water until the color is formed into a thin paste. Twenty grains of indigo, boiled with one and a half ounces of water until the mixture is reduced to about one drachm, will answer for the soap from four ounces of oil. The soap must not be too hot, nor must it be reboiled after adding the coloring matter, or the green will be destroyed." (*Can. Pharm. Journ.*, June, 1878.)

² Under the name of *Raiz de china de Méjico*, the Mexican Pharmacopœia recognizes the root of *S. rotundifolia* as diaphoretic and depurative, but, according to Malsch, this reference is incorrect. (See *A. J. P.*, 1879.)

ing, angular, smooth, and prickly; the young shoots are unarmed; the leaves ovate-oblong, acute, cordiform, five- or seven-nerved, coriaceous, smooth, twelve inches long and four or five broad, with footstalks an inch long, smooth, and furnished with tendrils. The young leaves are lanceolate-oblong, acuminate, and three-nerved. Large quantities of the root are said to be sent down the Magdalena River to Mompox and Carthagena.

S. ornata, Lemaire, *Illust. Hort.* xii.—This plant was recognized by both Flückiger and Hanbury, and by Bentley and Trimen as *S. officinalis*, and was described by Lemaire with a query to it to express his doubtfulness of its specific distinctness. The species is, however, now generally accepted. The plant has large 7-nerved leaves resembling *S. officinalis*. It is especially distinguished by the young leaves being mottled with white. See *Botanical Magazine*, vol. 115. t. 7054.

S. papyracea, Duham., *Arb.*, ed. Nov. 1, 242, is said to have foliage like *S. officinalis*, with a multiangular stem, with squamiform thorns on the angles, and petioles which are vaginate for one-fourth their length. It is thought to be the source of Para sarsaparilla.

S. medica, Schlecht. et Cham., in *Linnaea* (1831), 47.—This species has an angular stem, armed with straight prickles at the joints, and a few hooked ones in the intervals. The leaves are smooth, bright green on both sides, shortly acuminate, five-nerved, with the veins prominent beneath. They vary much in form, the lower being cordate, auriculate-hastate, the upper cordate-ovate. In the old leaves the petiole and midrib are armed with straight subulate prickles. The inflorescence is an umbel of from eight to twelve flowers, with a smooth axillary peduncle and pedicels about three lines long.

The medicinal species of *Smilax* grow in Mexico, Guatemala, and the warm latitudes of South America. The roots are very long and slender, and originate in great numbers from a common head or rhizome, from which the stems of the plant rise. The whole root with the rhizome is usually dug up, and as brought into market exhibits not unfrequently portions of the stems attached, sometimes several inches in length. The commercial sarsaparillas are conveniently divided into the mealy and non-mealy sarsaparillas. The first class comprises especially the Honduras, Guatemala, and Brazilian varieties; the second the Jamaica, Mexican, and Guayaquil sarsaparillas. A very convenient key for distinguishing the commercial sarsaparillas by certain anatomical characters has been devised by Lueresen in his *Handbuch der Medicin-pharm. Botanik*, ii. 404.

Honduras sarsaparilla is the variety most used in this country. Regarding the botanical origin of this drug little or nothing is definitely known, but it is believed by many botanists to be obtained from *S. officinalis*. It is brought from the Bay of Honduras, and

comes in bundles two or three feet long, composed of several roots folded lengthwise, and secured in a compact form by a few circular turns. These are packed in bales imperfectly covered with skins, each bale containing one hundred pounds or more. The roots are usually connected at one extremity in large numbers in a common head, to which portions of the stems are also attached. In some bundles are many small fibres, either lying loose or still adhering to the roots. The roots externally are a dirty grayish or reddish-brown; the cortical portion beneath the epidermis often appears amylaceous when broken.

The Jamaica or red sarsaparilla of foreign writers is little known by that name in the United States. The island of Jamaica is merely its channel of exportation to Europe.

Jamaica or red sarsaparilla is collected in Central America, especially in Costa Rica, and is the product of *S. ornata*, Hook. (see *Botan. Mag.*, cxv. 1889, t. 7054). It owes its name to the fact that it has been largely exported to Europe through the island of Jamaica. As found in commerce it is in rolls from twelve to eighteen inches long by four or five in thickness, composed exclusively of long slender many-radicle roots very loosely held together by a few turns. Sometimes it is pressed into large bales. It is further to be distinguished from Honduras sarsaparilla by its dark color, the greater abundance of coarse rootlets, the less quantity of starch, its relatively thick cortex, and its less sharp taste. Its epidermis is also redder than is commonly the case with Honduras sarsaparilla.

Cultivated Jamaica Sarsaparilla (*Roja Inglesa*) occurs in thick short rolls and is especially characterized by its yellow-brown or orange color. According to W. B. Hemsley Hooker's I. P. pl. 2589, it is the product of *S. utilis*, Hemsley, a species related to *S. ornata*, from which it differs by its long pediculated simple umbels.

The Mexican or Vera Cruz sarsaparilla is derived from *S. medica*. Although sometimes in bundles, it commonly comes in large, rather loose bales, weighing about two hundred pounds, bound with cords or leather thongs, and usually containing the roots folded upon themselves, and separately packed. These, as in the Honduras sarsaparilla, consist of a head or caudex with numerous long radicles, which, however, are somewhat smaller than in that variety, and have a thinner bark. They are often also much soiled with earth. It contains but little starch and has quadrangular endodermal cells, with thickened walls, and more or less oval lumen. It was formerly little esteemed; but, from the acrid taste which it possesses, it is probably of equal value to the other kinds. It is probably derived from *Smilax medica*.

Another variety is the Caracas sarsaparilla, brought in large quantities from La Guayra. It is in oblong packages, of about one hundred

pounds, surrounded with broad strips of hide, which are connected laterally with thongs of the same material, leaving much of the root exposed. The roots, as in the last variety, are separately packed, but more closely and carefully. The radicles are often very amylaceous internally, in this respect resembling the following variety.

The *Brazilian*, or, as it is called in Europe, the *Lisbon* or *Pará sarsaparilla*, is not very plentiful in commerce. It comes from the ports of Pará and Maranh, in cylindrical bundles from three to five feet in length by about a foot in thickness, bound about by close circular turns of a very flexible stem, and consisting of unfolded roots, destitute of caudex (rhizome) and stems, and having few radical fibres. It was also shown in the Brazilian exhibit in the Centennial Exhibition, neatly cut and tied into bundles about a foot long and eight inches in diameter. It is the variety of which Hancock speaks as celebrated throughout South America by the name of *Sarsa of the Rio Negro*, and is considered the most valuable variety of the drug. It is distinguished by the thinness of its cortex, the large amount of starch that it contains and its large, radially elongated endodermal cells. It was said by Martius to be derived from *Smilax syphilitica*; but Hancock considers that portion of it which comes from the Rio Negro, and is shipped at Pará, as the product of an undescribed species, certainly not *S. syphilitica*. As determined by Richard, it is the product of the *S. papyracea* of Poir.

The variety described by Bentley under the name of *Guatemala sarsaparilla* was collected in the province of Sacatapeques, about ninety miles from the sea. It is in cylindrical bundles about two feet eight inches long by four inches in diameter, composed of separate roots, arranged in parallel order, without rootstalk, and bound together by a few turns of the flexible stem of a monocotyledonous plant. The bundles resemble the Brazilian in arrangement, but are much less compact. It is amylaceous, has considerable acrimony, and is probably one of the most efficient varieties. Bentley ascribes it to *S. papyracea*. For a particular description of the root, see *P. J.*, xii. 472.

Guayaquil sarsaparilla, according to Spruce, grows in valleys on the western slopes of the equatorial Andes. It is usually not in bundles, but carelessly packed in bales. "The rhizome and a portion of the stem are often present, the latter being round and prickly. The root is dark, large, and coarse-looking, with a good deal of fibre. The bark is furrowed, rather thick, and not mealy in the slenderer portions of the root, which is near the rootstalk; but, as the root becomes stout, so its bark becomes smoother, thicker, and amylaceous, exhibiting when cut a fawn-colored or pale yellow interior."

Properties.—The dried sarsaparilla roots are several feet in length, about the thickness of a

goose-quill, cylindrical, more or less wrinkled longitudinally, flexible, and composed of a thick exterior cortical portion, covered with a thin easily separable epidermis, of an inner layer of ligneous fibre, and of a central pith. The epidermis is of various colors, generally ash-colored, grayish brown, or reddish brown, and sometimes very dark. It is composed of several rows of elongated flattened cells, with their walls thickened by secondary deposits. The cortical portion is in some specimens whitish, in others brown, and not infrequently of a pink or rosy hue. It is occasionally white, brittle, and almost powdery like starch. It is formed of a loose parenchymatous tissue, whose cells are often loaded with starch and raphides. Between it and the woody centre is a circle of small cells, which form the so-called nucleus sheath. The woody part is usually very thin and composed of longitudinal fibres, which allow the root to be split with facility through its whole length. Its vascular bundles contain pitted ducts and prosenchymatous cells. Scattered vascular bundles sometimes occur in the central medulla, which is composed of large medullary cells. The cells of the endoderm are nearly square in transverse section, and uniformly thickened.

Sarsaparilla in its ordinary state is nearly or quite inodorous, but in decoction acquires a decided and peculiar odor. To the taste it is mucilaginous and very slightly bitter, and, when chewed for some time, produces a disagreeable acid impression, which remains long in the mouth and fauces. It is officially described as "usually more than 1 M. in length, and 4 to 6 Mm. thick, with few or many fine roots adhering; externally varying from light gray-brown and smooth, with few deep and sharp wrinkles, to dark or orange-brown and less smooth, and with more and smaller wrinkles; internally whitish, with a thick, mealy or sometimes horny cortex, a circular wood-zone, and a thick pith; fracture tough; nearly inodorous; taste mucilaginous, somewhat sweetish and bitter, slightly acid. The thick, woody, knotty rhizome, if present, should be removed." *U. S.* The root is efficient in proportion as it possesses this acrimony, which is said by some authors to be confined to the cortical portion, while the ligneous fibre and medullary matter are insipid and inert. Hancock avers that all parts are equally acid and efficacious. The truth is probably between the two extremes, and, as in most medicinal roots, it must be admitted that the bark is more powerful than the interior portions, while these are not wholly inactive. The virtues of the root are communicated to water, cold or hot, but are impaired by long boiling. They are extracted also by diluted alcohol. According to Hancock, the whole of the active matter is not extracted by water. In South America it is the custom to prepare sarsaparilla by digestion in wine or spirit, or by infusion in water with additions which may produce the vinous

fermentation and thus add alcohol to the menstruum. The same result, as to the superior efficacy of alcohol as a solvent of the acrid principle of sarsaparilla, has been obtained by the French experimentalists. It has been suggested that sarsaparilla, the virtues of which are admitted to be impaired by long boiling, might also be injured by the degree of heat applied in the water or steam bath. But the contrary appears to have been proved by J. F. Judge of Cincinnati. (*Proc. A. Ph. A.*, 1873, p. 595.)

Parillin. (Smilacin. Pariglin. Salseparin. Paralimic acid.)—The crystalline principle in which the virtues of sarsaparilla reside is now called *parillin*. It was first discovered by Pallotta, who described it in 1824 under the name of *pariglin*. Subsequently, Folchi supposed that he had found another principle, which he called *smilacin*. Flückiger recommends the preparation of *parillin* by exhausting the crushed root with warm alcohol and distilling the tincture until the residue weighs one-sixth of the root. It is then gradually mixed with one and a half times its weight of water, and after several days the liquid is decanted from the light yellow precipitate, which is then mixed with about half its volume of alcohol, transferred to a filter, and washed with alcohol of 20 or 30 per cent. because *parillin* is less soluble in weak alcohol than in strong alcohol. The yield was 0.18 and 0.19 per cent. It is white, inodorous, almost tasteless in the solid state, but bitter, acrid, and nauseous when dissolved in alcohol or water. It is very slightly soluble in cold water, but more readily in boiling water, without crystallizing on cooling. It is very soluble in alcohol, especially at the boiling temperature. Ether and the volatile oils also dissolve it. Its aqueous solution has the property of frothing very much on agitation. According to Flückiger, concentrated sulphuric acid yields a yellow solution, which, on absorbing moisture, gradually turns cherry-red; warm diluted sulphuric acid colors *parillin* greenish, then red, and finally brown; phosphoric acid has a similar reaction, but the color is more greenish-yellow. The aqueous solution is precipitated by alcoholic solution of lead acetate, by lead subacetate, and by tannin, and when warmed reduces alkaline copper tartrate, but does not react with other tests for sugar until after it has been boiled with a dilute acid, when the solution acquires a green fluorescence. This is best observed if a trace of *parillin* is dissolved in warm concentrated sulphuric acid, and disappears on dilution with water or on neutralizing with ammonia. *Parillin* is not sternutatory; its acrid taste is best observed in alcoholic solution. (See *A. J. P.*, xii. 245.) The solutions of *parillin* are without acid or alkaline reaction. By treatment with dilute mineral acids, it is resolved into *parigenin* and sugar. Poggiale found *parillin* both in the cortical and in the medullary part of the root, but most largely in the former. W. von Schulz

(*P. J.*, 1892, 6) has shown that Dragendorff's *smilacin* or *sarsaparill-saponin*, $C_{20}H_{32}O_{10}$, *sarsa-saponin*, $C_{22}H_{36}O_{10}$, discovered by himself, and Flückiger's *parillin*, $C_{26}H_{44}O_{10}$; are three homologous compounds all belonging to the same series, having the general formula $C_nH_{2n-8}O_{10}$. These three all split up into *sarsa-sapogenin* (parigenin of Flückiger) and one or more molecules of glucose on boiling with dilute acids. Kobert (*A. J. P.*, 1892, 465) comes to practically the same results, stating the constituents to be *parillin* ($C_{26}H_{44}O_{10} + 2\frac{1}{2}H_2O$), insoluble in water; *saponin* (*sarsaparill-saponin*), $5(C_{20}H_{32}O_{10} + 2\frac{1}{2}H_2O)$, soluble in water; and *sarsa-saponin*, $12(C_{22}H_{36}O_{10} + 2H_2O)$, easily soluble in water, and the most poisonous of the constituents.

The sarsaparilla of commerce is apt to be nearly if not quite inert, either from age, or from having been obtained from inferior species of *Smilax*. This inequality of the medicine, with the improper modes of preparing it long in vogue, has probably contributed to its variable reputation. The only criterion of good sarsaparilla to be relied on is the taste. If it leave a decidedly acrid impression in the mouth after having been chewed for a short time, it may be considered efficient; if otherwise, it is probably inert. Various false sarsaparillas have been sent into commerce from South America. For description by C. Hartwich see *A. Pharm.*, July, 1902.

Uses.—Few medicines have undergone greater changes of reputation. About the middle of the sixteenth century it was introduced into Europe as a remedy for the venereal disease, in which it had been found very useful in the recent Spanish settlements in the West Indies. After a time it fell into disrepute, and was little employed until about a century ago, when it was again brought into notice by Fordyce and others, as a useful adjuvant and corrigent of mercury in *lues venerea*. Since that period very different opinions have been entertained of it. Some, among whom was Cullen, considered it wholly inert; others, on the contrary, have had the most unbounded confidence in its powers. The probable cause of much of this discrepancy has been already mentioned. Experience, among both regular practitioners and empirics, would seem to have placed its efficacy beyond reasonable doubt. Its most extensive and useful application is in the treatment of *secondary syphilis* and *sypiloid diseases* and that shattered state of the system which sometimes follows the imprudent use of *mercury* in these affections. It is also employed, though with less obvious benefit, in *chronic rheumatism*, *scrofulous affections*, certain *cutaneous diseases*, and other depraved conditions of health. Its mode of action is less evident than its ultimate effects. It is said to increase the perspiration and urine; but, allowing it to do so, the effect is too slight to explain its remedial influence, and even that which is produced has been ascribed by some

to the medicines with which it is generally associated, or to the liquid in which it is exhibited. In this ignorance of its precise *modus operandi*, we call it an alternative.

Sarsaparilla may be administered in the form of infusion, compound decoction, compound syrup, or fluidextract. A beer made by fermenting an infusion of the drug with molasses is said to be a popular remedy in South America.¹ The smoke of sarsaparilla has been highly recommended in asthma. (*J. P. C.*, xviii. 221.)

Dose, thirty to sixty grains (2 to 3.9 Gm.).

Sassafras variifolium, Salisb., O. Kuntze; *Sassafras Sassafras*, Karsten, *Deutsch. Fl.* (1880-83).—*Laurus Sassafras*, Linn., *Sp. Pl.* 1753.—*Laurus variifolia*, Salisb., *Prodromus*, etc., 1796.—*Sassafras officinale*, Nees and Esenbeck and Ebermaier, 1830.—This is an indigenous tree, of medium size, rising in favorable situations from thirty to fifty feet, with a trunk about a foot in diameter. In the Southern States it is sometimes larger, and in the northern parts of New England is little

more than a shrub. The bark of the stem and large branches is rough, deeply furrowed, and grayish; that of the extreme branches or twigs is smooth and beautifully green. The leaves, which are alternate, petiolate, and downy when young, vary much in their form and size even upon the same tree. Some are oval and entire, others have a lobe on one side, but the greater number are three-lobed. Their mean length is four or five inches. The flowers, which appear before the leaves, are small, of a pale greenish-yellow color, and disposed in racemes which arise from the branches below the leaves and have linear bracts at their base. The corolla is divided into six oblong segments. The male flowers have nine stamens; the hermaphrodite, which are on a different plant, have only six, with a simple style. The fruit is an oval drupe, about as large as a pea, of a deep blue color when ripe, and supported on a red pedicel, enlarged at the extremity into a cup for its reception. For the microscopical character of the root and bark, see E. S. Bastin, *A. J. P.*, June, 1895. See also *Ph. Rev.*, 1899, 450.

The sassafras is common throughout the United States, and extends into Mexico. The fresh flowers have a slightly fragrant odor, and almost all parts of the plant are more or less aromatic. The best time for collecting the pith is after the occurrence of frost in autumn, and the same is the case also with the bark of the root. The wood of the root is brownish white, the bark spongy and divisible into layers. Although the *Br. Ph.* recognizes the whole root as official, the activity resides in the bark, which alone should be employed.

Bark of Sassafras Root.—As found in commerce, this is usually in small irregular fragments, sometimes invested with a brownish epidermis, sometimes partially or wholly freed from it, of a reddish or rusty cinnamon hue, very brittle, and presenting when freshly broken a lighter color than that of the exposed surfaces. The living bark is nearly white, but becomes colored, on exposure, immediately after collection. It is officially described as "in irregular transversely curved, reddish-brown pieces, of variable length and 0.5 to 5 Mm. thick; outer surface nearly smooth; inner surface obscurely short-striate; soft, fragile, with a short, corky fracture; strongly fragrant; taste mucilaginous, aromatic, and astringent." *U. S.* These properties are extracted by water and alcohol. According to Reinsch, the bark contains a heavy and light volatile oil, camphorous matter, fatty matter, resin, wax, a peculiar decomposition product of tannic acid called *sassafrid*, tannic acid, gum, albumen, starch, lignin, and salts. (See *Oleum Sassafras*, page 875.) The sassafrid bears some analogy to cinchonic red, and, like it, appears to be a derivative of the tannin, which exists in much larger proportion in the fresh bark than in that long kept. (Procter, *A. J. P.*, 1866, p. 490.) Owing to its volatile oil and

¹ *Sarsaparilla Beer*.—The following is Hancock's formula. "Take of Rio Negro sarsa, bruised, 2 pounds; bark of guaiac, powdered, 8 ounces; raspings of guaiac wood, anise-seeds, and licorice root, each 4 ounces; mezereon, bark of the root, 2 ounces; treacle [molasses], 2 pounds; and a dozen bruised cloves; pour upon these ingredients about four gallons of boiling water, and shake the vessel thrice a day. When fermentation has well begun, it is fit for use, and may be taken in the dose of a small tumblerful twice or thrice a day." This formula is worthy of attention; but the bark of guaiacum, which is not kept in the shops, might be omitted, or replaced by the wood.

tannic acid, the bark of sassafras root is an aromatic stimulant and astringent. It is used almost exclusively as an adjuvant to other more efficient medicines, the flavor of which it improves, while it renders them more acceptable to the stomach. The volatile oil may be used as an aromatic. In overdoses it is capable of producing marked narcotic poisoning, and it is said to act upon the lower animals as a narcotic. John Bartlett has reported several cases in which its use apparently caused abortion.

Sassafras Pith.—This is in slender cylindrical pieces, very light and spongy, about 5 Mm. in diameter, with a mucilaginous taste, and in a slight degree the characteristic flavor of the sassafras. It is officially described as "in more or less cylindrical, often curved or coiled pieces of variable length and about 5 Mm. in diameter, whitish, very light, with a slight odor and a mucilaginous taste. When macerated in water Sassafras Pith yields a mucilage which is not precipitated upon the addition of alcohol." *U. S.* It abounds in a gummy matter, which it readily imparts to water, forming a limpid mucilage, which is not precipitated by alcohol, but has much less tenacity than that of gum arabic and will not answer as a substitute in the suspension of insoluble substances. This mucilage is much employed as a soothing application in inflammation of the eyes, and forms an agreeable and useful drink in *dysenteric, catarrhal, and nephritic* diseases. It may be prepared by adding a drachm of the pith to a pint of boiling water.

Dose, of sassafras bark, one to two drachms (3.9 to 7.7 Gm.).

SCAMMONIÆ RADIX. *Br.*

SCAMMONY ROOT

(sca-mo-ni-æ rā'dix)

"The dried Root of *Convolvulus Scammonia*, *Linn.*" *Br.*

The root of the scammony is recognized by the British Pharmacopœia solely for the preparation of the resin. It is officially described as "brownish-gray or yellowish gray, tapering or nearly cylindrical roots, varying usually from one to three inches (two and a half to seven and a half centimetres) or more in diameter. The Root is frequently contorted and the surface longitudinally furrowed. It is enlarged at the crown, and bears the remains of slender aerial stems. The fracture is very coarsely fibrous; internally the color is light or dark gray. The section exhibits an abnormal wood, consisting of numerous irregularly arranged wood bundles; and, when examined under the microscope, appears beset with starch

grains of characteristic shape, and, especially in the cortical region, with resin-cells. Odor characteristic; taste at first somewhat sweet, afterwards slightly acrid. It yields to alcohol (90 per cent.) a resin which should have the properties of Scammony Resin." *Br.* The wood consists of compressed pale brown, coarsely porous, usually subdivided fibres in a parenchymatous tissue similar to the bark. For microscopic structure, see *Dragendorff's Jahresbericht*, 1875.¹

The root of the male jalap (*orizaba root*, *Purgo macho*) has recently largely replaced in commerce the scammony root on account of its containing a much larger percentage of resin chemically indistinguishable from that of scammony. The Levant or true scammony root, it is said, averages a little under 9 per cent. of resin, while the Mexican root² usually yields over 15 per cent. Male jalap occurs in transverse pieces one half to an inch in thickness and two to four inches in diameter or in the case of the smaller roots in pieces three or four inches long sometimes obliquely cut, the transverse slices show concentric rings with protruding coarse fibres which at once distinguishes it from the true scammony in which the vascular bundles are scattered.

¹ Large quantities of a false scammony root of unknown botanical origin have appeared in the London market. The root is 2 to 3 inches in diameter with a thin, brittle, blackish-brown bark, and on transverse section six or seven rings of wood. It is odorless and tasteless. (See *P. J.*, May, 1901, 596.)

² *Mexican Scammony Root.*—Mexican scammony root has been identified by E. M. Holmes as being undoubtedly the root of *Ipomœa orizabensis*, and is described as follows: The appearance is quite characteristic and quite different from that of scammony root. It occurs mostly in transverse slices, showing concentric rings, from which coarse fibres protrude on both of the transverse surfaces. The sections are mostly those of the larger portion of the root, and vary from 2 to 3 in. or more in diameter, but are only about ½ in. to ¾ in. in thickness. The smaller roots are about 1 in. or so in diameter, but are frequently 3 or 4 in. long; a few pieces are obliquely cut. The concentric arrangement of the vascular bundles at once distinguishes it from the root of *Convolvulus scammonia*, in which they are scattered and somewhat rounded, forming islands, as it were, in the softer tissue. It appears that during 1903 there was an importation of over 3,000 bags, which sold readily to the German makers of scammony resin. Analyses made showed from 6.4 to 22.2 per cent. of resin, but most of it yielded about 17 per cent. While chemically there appears to be no difference between scammony resin and the resin of *Ipomœa orizabensis*, it remains to be ascertained if they are identical in their physiological action. At the request of Holmes, Harold Dean determined the amount of resin in a specimen and, in a separate paper, gives the method employed and the results, as follows: The drug was powdered, exhausted by percolation with alcohol (90 per cent.), the greater part of the alcohol distilled off, and the resulting strong tincture poured into three times its volume of water. The resin separated as a mass of honey-like consistence. It was well washed with boiling water until the washings were free from sugar and from color, and then dried on a water bath until the weight was constant. The yield of resin amounted to 18.5 Gm. from 100 Gm. of the powdered drug; this is the highest percentage yet recorded from this source. The dried resin was pale brown, and almost entirely soluble in ether, the insoluble portion from 18.5 Gm. weighing less than 0.25 Gm. It had the general characters of scammony resin. The powdered drug, dried at 100° C., yielded 9.89 per cent. of ash. (*P. J.*, March 5, 1904, 226, 327.)

Uses.—Scammony root in substance is not used medicinally, but solely for making resin of scammony.

Scammonium Alepense; Scammonée d'Alep, Fr. Cod.; Scammonium, G.; Scamonea, It.; Escamonea, Sp.

Convolvulus Scammonia, L., Sp. Pl. (1753) 55; Willd., Sp. Plant. i. 845; B. & T. 187. This vine has a perennial, tapering root, from three to four feet long, from nine to twelve inches in circumference, branching towards its lower extremity, covered with a light gray bark, and containing a milky juice. The stems are numerous, slender, and twining, extending sometimes fifteen or twenty feet upon the ground or on neighboring plants, and furnished with smooth, bright green, arrow-shaped leaves, which stand alternately upon long footstalks. The flowers are placed in pairs, or three together, upon the peduncles, which are round, axillary, solitary, and of nearly twice the length of the leaf. The plant is a native of Syria, Anatolia, and the Archipelago.

Scammony is collected, according to Russell, in the following manner. In the month of June, the earth is cleared away from about the root, the top of which is cut off obliquely about two inches from the origin of the stems. The milky juice which exudes is collected in shells, or other convenient receptacle, placed at the most depending part of the cut surface. A few drachms only are collected from each root. The juice from several plants is put into any convenient vessel, and concretes by time. In this state it constitutes genuine scammony, but is very seldom exported. It is generally prepared for the market by admixture, while it is yet soft, with the expressed juice of the stalks and leaves, with wheat flour, chalk, ashes, fine sand, etc., and it has been supposed that scammony sometimes consists wholly or in great part of the expressed juice of the root evaporated to dryness by exposure to the sun or by artificial heat. According to Landerer, the roots from which the juice has been collected are in some places boiled with water in copper vessels, and the extract added to the juice, not so much with the purpose of adulteration as under the impression that it favorably modifies the action of the drug. Scammony is exported chiefly from Smyrna, though small quantities are said to be sent

out of the country at Alexandretta, the seaport of Aleppo. Pereira was informed by a merchant who resided in Smyrna that it is brought in a soft state into that city upon camels, and afterwards adulterated by individuals called scammony makers. The adulteration appears to be conducted in conformity with a certain understood scale, more or less foreign matter being added according to the price. The materials employed are chiefly chalk and some kind of flour or meal. Very little comparatively is exported perfectly pure. We obtain scammony either directly from Smyrna, or indirectly through some of the Mediterranean ports.¹

¹An interesting account of the collection and preparation of scammony in Anatolia, in the vicinity of Smyrna, has been communicated by S. H. Maltass to the P. J., xiii. 264. The juice is collected in the same manner as described by Russell in reference to Syria. The product, however, of each plant is somewhat less. In some districts, according to Maltass, ten plants produce only a drachm of scammony; in others the average from each root is a drachm, and in a good soil a plant four years old will yield two drachms. The juice received in the shells is mixed with another portion scraped from the cut surface of the root, and this mixture is the pure or *lachryma scammony*. Only a small quantity of this is taken to Smyrna, the greater part being adulterated by the peasants before it reaches the markets. Sometimes the juice is worked up with a decoction of the roots, in which case it is black, heavier than the preceding, and not so easily broken. Sometimes they add a calcareous earth, in a proportion varying from 10 to 150 per cent. The kind thus prepared is usually kept for some time in Smyrna, and is apt to ferment, so as to become porous and lose its gloss. It is in irregular lumps, and is the kind usually sold in London as *lachryma scammony*. Another kind sold in London in rough lumps, and probably under the same name, is prepared in the interior of the country by mixing the juice with wheat starch, ashes, earthy matters, gum arabic or tragacanth, and sometimes wax, yolk of egg, pounded scammony roots and leaves, flour, or resin. A kind much used in Great Britain is prepared by the Jews in Smyrna, and is in the form of cakes as described in the text. It is of two qualities. The *first quality* is prepared by mixing *skilip* (which is an inferior kind of scammony scraped at Angora) and consists of from 30 to 40 per cent. of juice and 60 to 70 of starch) with 60 per cent. of inferior scammony from the neighborhood of Smyrna; the *second quality*, by mixing *skilip* with about 30 per cent. of the latter kind, and adding about 10 per cent. of gum arabic and black-lead. The *first quality* contains about 50 per cent. of resin, the second about 30 per cent. For an account of specimens of scammony sent by Maltass from Smyrna, see a paper by D. Hanbury in P. J. (xiii. 268).

Ch. Bouller of Algiers, gives the following account of the collection of scammony in the north-western parts of Anatolia. The plant is not cultivated, but grows in rocky places covered with brushwood. At the flowering period, about the end of June and beginning of July, the peasants go forth in search of localities among the mountains where it is most abundant, and, having satisfied themselves on this point, return home, provide themselves with the requisite implements, and set out for the place of collection. Clearing away the brushwood and stems, the peasant digs deeply around the root, then cuts off the top obliquely, and affixes a mussel shell to the root so as to receive the juice as it flows from the dependent part. He then passes on to other plants, upon which he operates in like manner. After a time he retraces his steps, and empties the shells successively into a tinued copper vessel. Next day he goes over the same ground, and scrapes with a knife from the cut surface the juice which has in the mean time flowed out and partly concreted. This he mixes with that previously collected, and, when his vessel is full, takes it to some neighboring market, where it is bought up and sent to the wholesale druggists at Constantinople and Smyrna. The juice reaches the market in a pasty state, and whitish like cheese,

The name of *Aleppo scammony* was formerly given to the better kinds of the drug, and of *Smyrna scammony* to those of inferior quality,—the distinction having probably originated in some difference in the character of the scammony obtained at these two places. But no such difference now exists, as scammony is brought from Smyrna of every degree of purity. It has been customary, in this country, to designate the genuine drug, of whatever quality, as Aleppo scammony, while the name of Smyrna scammony has been given to a spurious article manufactured in the south of France, and to other factitious substitutes. It is quite time that these terms should be altogether abandoned. We shall treat of the drug under the heads of genuine and factitious scammony.

Genuine Scammony.—This is sent into commerce in drums or boxes, and is either in irregular lumps, in large solid masses of the shape of the containing vessel, into which it appears to have been introduced while yet soft, or in circular, flattish or plano-convex cakes. It seldom reaches us in an unmixed state. Formerly small portions of pure scammony were occasionally to be met with in Europe, contained in the shells in which the juice was collected and dried. This variety, denominated *scammony in shells*, is now scarcely to be found. The pure drug is called *virgin scammony*. It is in irregular pieces, often covered with a whitish-gray powder, friable and easily broken into small fragments between the fingers, with a shining grayish-green fracture soon passing into greenish black, and exhibiting under the microscope minute air-cells and numerous gray semi-transparent splinters.¹ It is easily pulverized, affording a pale ash-gray powder. When rubbed with water it readily forms a milky emulsion. It has a rather strong, peculiar odor, comparable to that of old cheese. The taste is feeble at first, and afterwards somewhat acrid, but without bitterness. It gives no evidence, when the requisite tests are applied, of the presence of starch or calcium carbonate, leaves but a slight residue when burned, and yields about 80 per cent. of its weight to ether. Considerable quantities of what is called virgin scammony have been imported into this country since the drug-law went into operation; but, though some specimens are tolerably pure, the drug, on the whole, falls far short of the proper standard. E. R. Squibb examined many specimens, and found the proportion of resin to vary from 25 to 79.7 per cent.; only two or three, out of more than 30 examined, approaching the latter de-

gree of purity within 10 per cent. Squibb gives the following description of the drug imported as *virgin scammony*. "It generally occurs in solid square tin boxes, containing 25 to 28 pounds each. Occasionally, however, it is in round wooden boxes or drums of a similar capacity. The scammony is in irregular, rough and fissured masses of various sizes, sometimes porous, but commonly solid, hard, and semi-resinous, having a tough, dull fracture. It is of a very dark grayish-green color internally, often nearly black, but more of an ash color externally. It is rarely dry enough to be pulverulent, yet still more rarely too moist to be rubbed into coarse powder, and it generally loses 6 per cent. in drying sufficiently to make a fine powder." (A. J. P., Jan. 1863, p. 49.)

Properties.—The official description and tests for scammony are as follows: "In circular cakes or irregular, angular pieces of various sizes, greenish-gray or brownish-black, often covered with a grayish-white powder; very brittle, breaking with an angular fracture, porous and of a resinous lustre; internally of a uniform brownish-black color, more or less translucent in thin fragments; odor peculiar, somewhat cheese-like; taste slightly acrid. Scammony is easily reduced to an ash-gray powder, which when triturated with water yields a greenish emulsion that does not effervesce on the addition of diluted hydrochloric acid; a decoction of Scammony, when cold, does not become blue with iodine T.S.; an alcoholic solution is not colored blue on the addition of tincture of ferric chloride; not less than 75 per cent. should be soluble in ether, and when the residue left on the evaporation of the ethereal solution is dissolved in a hot solution of potassium or sodium hydroxide, it is not reprecipitated on the addition of diluted sulphuric acid; ash not more than 3 percent." *U. S.* "It should afford only the slightest reactions with the tests for starch, and should yield at least 70 per cent. of resin soluble in ether, and not more than 3 per cent. of ash on incineration. An alcoholic solution should not afford a blue color with *test-solution of ferric chloride* (absence of guaiacum resin)." *Br.*

The form of scammony chiefly found in our markets is that in circular cakes. These are sometimes flattish on both sides, but generally somewhat convex on one side and flat on the other, as if dried in a saucer or other shallow vessel. They are from four to six inches in diameter, and from half an inch to an inch and a half or even two inches thick in the centre, and are often found in fragments. They are hard and heavy, with a faintly shining roughish fracture, and when broken exhibit in general a structure very finely porous, sometimes almost compact, and in a very few instances cavernous. Their color externally is a dark ash or dark olive or slate color approaching to black; internally somewhat lighter and grayish, with an occasional tinge of green

except where exposed to the air. It is in these centres of trade, or on its way from the collectors, that the drug undergoes the various sophistications to which it is subjected.—the peasant himself being usually honest and not disposed to adulterate. (*Ibid.*, April, 1860, p. 521.)

¹ According to Maltass, the purest scammony has a reddish-black fracture, unless it has been mixed with water in its preparation, in which case it is black and very glossy. (*P. J.*, xiii. 266.)

or yellow, but deepening by exposure. The small fragments are sometimes slightly translucent at the edges. The mass, though hard, is pulverizable without great difficulty, and affords a light-gray powder. It imparts to water with which it is triturated a greenish milky appearance. The odor is rather disagreeable, and similar to that of the pure drug. The taste, very slight at first, becomes feebly bitterish and acrid. This kind of scammony is never quite pure, and much of it is considerably adulterated. In some of the cakes calcium carbonate is the chief impurity; in others the adulterating substance is probably meal, as evidences of the presence of starch and lignin are afforded, and in others, again, both these substances are found. Christison discovered in the chalky specimens from 15 to 38 per cent. of calcium carbonate; in the amylaceous, from 13 to 42 per cent. of impurity. It was probably the flat, dark-colored, compact, difficultly pulverizable, and more impure cakes that the name of *Smyrna scammony* was formerly given. These have been erroneously ascribed by some to *Periploca secamone*, a plant growing in Egypt.

Scammony is ranked among the gum-resins. It is partially dissolved by water, much more largely by alcohol and ether, and almost entirely, when pure, by boiling diluted alcohol. Its active ingredient is resin, which constitutes from 80 to 90 per cent. of pure dry scammony. (See *Resina Scammonii*.) The gum-resin has been analyzed by various chemists, with varying results, as the character of the specimens examined is insufficiently determined by the terms Aleppo and Smyrna scammony employed to designate them. The resin is now known to be identical with that found in the root of the Mexican *Ipomœa orizabensis*, known in commerce as male jalap, and the name *jalapin* is given to it. (See *Jalap*.) Bouillon-Lagrange and Vogel obtained from 100 parts of Aleppo scammony, 60 of resin, 3 of gum, 2 of extractive, and 35 of insoluble matter; from the same quantity of Smyrna scammony, 29 parts of resin, 8 of gum, 5 of extractive, and 58 of vegetable remains and earthy substances. It is obvious that both the specimens upon which they operated were very impure. Marquart found in pure scammony (*scammony in shells*) 81.25 per cent. of resin, 3.00 of gum with salts, 0.75 of wax, 4.50 of extractive, 1.75 of starchy envelopes, bassorin, and gluten, 1.50 of albumen and lignin, 3.75 of ferruginous alumina, chalk, and magnesium carbonate, and 3.50 of sand.

Christison found different specimens of pure scammony to contain, in 100 parts, from 77 to 83 parts of resin, from 6 to 8 of gum, from 3.2 to 5 of lignin and sand, and from 7.2 to 12.6 of water, with occasionally a little starch, probably derived accidentally from the root, and not in sufficient quantity to cause a cold decoction of the gum-resin to give a blue color with iodine. Hanbury of London, found 91.1

per cent. of resin in the purest scammony in shells. As already stated, scammony is seldom quite pure as found in commerce. Much of it contains not more than 50 per cent. of the resin, some not more than 42 per cent., and the worst varieties as little as 10 per cent., or even less. Sometimes the cakes are of good quality on the outside, and inferior within. In view of this uncertainty as to the strength of scammony, it is undoubtedly best to abandon its internal use altogether, employing only the resin, which is of uniform strength. Indeed, the resin has been officially substituted for the gum-resin in the compound extract of colocynth. Aslanoglu (*Chem. News*, 1901, 682) proposed a quantitative valuation of scammony based on its treatment with ether and oil of turpentine; see also Dowzard's method (*P. J.*, April, 1904, 469).

Factitious Scammony. Montpellier Scammony.—Much spurious scammony was manufactured in the south of France, said by Guibourt to be made from the expressed juice of *Cynanchum monspeliacum* (*C. acutum*, L.), incorporated with various resins and other purgative substances. Thorel, however, a pharmacist of Avallon, denies that this plant is employed in its preparation. (*J. P. C.*, xx. 107.) It has been occasionally imported into the United States and sold as Smyrna scammony. It is usually in flat semicircular cakes, four or five inches in diameter and six or eight lines thick, blackish both externally and within, very hard, compact, rather heavy, of a somewhat shining and resinous fracture, a feeble balsamic odor wholly different from that of genuine scammony, and a very bitter nauseous taste. When rubbed with the moistened finger it becomes dark gray, unctuous, and tenacious. We have seen another substance sold as Smyrna scammony, which was obviously spurious, consisting of blackish, circular, flat cakes, or fragments of such cakes, rather more than half an inch thick, very light, penetrated with small holes, as if worm-eaten, and when broken exhibiting an irregular, cellular, spongy texture. It is affirmed that a resin obtained from the root of *Convolvulus althæoides* of Southern Europe is sometimes substituted for scammony. Pereira described a factitious substance sold as *Smyrna scammony*, which was in circular flat cakes about half an inch thick, blackish, and of a slaty aspect, breaking with difficulty, of a dull, black fracture and of the sp. gr. 1.412. Moistened and rubbed, it had the odor of guaiac; the adulteration was also detected by chemical tests.

Uses.—Scammony is an energetic cathartic, likely to occasion griping, and sometimes operating with harshness. It was known to the ancient Greek physicians, and was much employed by the Arabians, who used it as a purgative and externally in skin diseases. On account of its occasional violence, it is seldom administered, except in combination with other cathartics, the action of which it promotes,

while its own harshness is mitigated.¹ It should be given in emulsion with mucilage, sugar, almonds, licorice, or other demulcent, and its disposition to gripe may be counteracted by the addition of an aromatic.

Dose, from five to ten grains (0.32 to 0.65 Gm.).

SCILLA. *U. S.*, Br.

SQUILL

(scil'la)

"The bulb of *Urginea maritima* (Linné) Baker (Fam. *Liliaceæ*), deprived of its dry, membranaceous outer scales, cut into thin slices and carefully dried, the central portions being rejected." *U. S.* "The bulb of *Urginea Scilla*, *Steinh.*, divested of its dry membranous outer scales, cut into slices, and dried." *Br.*

Squills; Scille, *Fr. Cod.*; Bulbus Scillæ, *P. G.*; Meerzwiebel, *G.*; Scilla, *It.*; Escila (Bulbo de), *Cebolla albarrana*, *Sp.*

For *Urginea*, *Br. Add.*, see PART II.

Urginea maritima (L.), Baker, *Journ. Linn. Soc.* (1873), 221.—*Urginea Scilla*, Steinheil, *Ann. Sci. Nat.* (1834), 330.—*Scilla maritima*, L., *Sp. Pl.* (1753) 308; Willd., *Sp. Plant.* ii. 125.—This is a perennial plant, with fibrous roots proceeding from the bottom of a large bulb, which sends forth several long, lanceolate, pointed, somewhat undulated, shining, deep-green leaves. From the midst of the leaves a round, smooth, succulent flower-stem rises, from one to three feet high, terminating in a long, close spike of whitish flowers. These are destitute of calyx, and stand on purplish peduncles, at the base of each of which is a linear, twisted, deciduous floral leaf. The squill grows on the sea coast of Spain, France, Italy, Greece, and the other countries bordering on the Mediterranean. The bulb is the official portion. It is generally dried for use, but is sometimes imported in the recent state packed in sand.

Properties.—The fresh bulb is pear-shaped, usually larger than a man's fist, sometimes as large as the head of a child, and consists of fleshy scales attenuated at their edges, closely applied over each other, and invested by exterior scales so thin and dry as to appear to constitute a membranous coat. There are two varieties, distinguished as the *red* and the *white squill*. In the former the exterior coating is of a deep reddish-brown color, and the inner

scales have a whitish rosy or very light pink epidermis, with a yellowish-white parenchyma; in the latter the whole bulb is white. They do not differ in medicinal virtue. The bulb abounds in a viscid, very acrid juice, which causes it to inflame and even excoriate the skin when much handled. By drying, this acrimony is very much diminished, with little loss of medicinal power. The bulb loses about four-fifths of its weight in the process. Vogel found 100 parts of fresh squill to be reduced to 18 by desiccation. The process is somewhat difficult, in consequence of the abundance and viscosity of the juice. The bulb is cut into thin transverse slices, and the pieces dried separately by artificial or solar heat. The outer and central scales are rejected, the former being dry and destitute of activity, the latter too fleshy and mucilaginous.

Dried squill, as found in commerce, is in irregular oblong pieces, often more or less contorted, of a dull yellowish-white color with a reddish or rosy tint, sometimes entirely white, slightly diaphanous, brittle and pulverizable when perfectly dry, but often flexible from the presence of moisture, for which it has a great affinity. Occasionally a parcel will be found consisting of vertical slices, some of which adhere together at the base. The odor is very feeble, the taste bitter, nauseous, and acrid. It is officially described as "in irregular, more or less curved, somewhat translucent, yellowish-white or reddish-white segments, 3 to 5 Cm. long, brittle and pulverizable when dry, tough and flexible when damp; odor slight; taste mucilaginous, bitter, and acrid." *U. S.*

The virtues of squill are extracted by water, alcohol, and vinegar. It has been analyzed by Vogel, J. H. Marais, Lebourdais, Tilloy, Merck, and lastly by Schmiedeberg (*Zeit. Physiol. Chem.*, 111, 112) with varying results. The bitter principle, not yet obtained pure, is *scillitin*. Merck, however, obtains three compounds of this class,—*scillipicrin*, *scillitoxin*, and *scillin*. Jarmersted (*A. E. P. P.*, 11, 22) obtained a glucoside which he called *scillain*, but which seems to be identical with *scillitoxin*. Schmiedeberg (*loc. cit.*) found a peculiar mucilage, analogous to dextrin, which he calls *sinistrin*, (C₆H₁₀O₅)_n. It is white, easily soluble in water, insoluble in alcohol, lævo-rotatory; on boiling with dilute sulphuric acid it yields levulose and an inactive sugar of reducing properties. The mucilage is not affected by saliva or diastase. This last statement, however, was contradicted by F. Kurtz (*A. J. P.*, 1894, 246), who says that diastase acts upon it, producing a reducing sugar. Kurtz (*loc. cit.*) also obtained a reducing sugar (probably dextrose) along with the gum direct by extracting the bulb with hot alcohol. S. Wanizewski (*A. J. P.*, 1893, 498) found *scillinine*, soluble in alcohol, but insoluble in water and in chloroform; *scillapierine*, soluble in both water and alcohol, and *scillamarine*, soluble in both chloroform and alcohol. The bulbs of *Scilla marit-*

¹ *Triplew Pills*.—J. W. Francis of New York City, employed a combination of purgatives which afterwards became very well known as triplew pills. The original formula, obtained through E. R. Squibb, is as follows: Powdered Scammony, Powdered Socotrine Aloes, Blue Mass, of each, 1 *troynounce*; Croton Oil, 20 *minims*; Oil of Caraway, 1½ *fluidrachms*; Tincture of Aloes and Myrrh, 2 *fluidrachms*. Mix well, and make into 500 pills. The usual aperient or laxative dose is one pill at bedtime until the natural condition is restored. (*Proc. A. Ph. A.*, 1872.)

ima also yield a slightly colored liquid oil of unpleasant odor when distilled in a current of steam. (*Husemann's Pflanzenstoffe*, 2d ed., p. 406.)

Examined by the microscope, the bulb is seen to be pervaded by innumerable minute acicular crystals of calcium oxalate. According to Hartwich, the mucilage occurs either in the form of large drops, filling the parenchymatous cells, or as masses enclosing the raphides. For an elaborate microscopic study, with plates, see *A. Pharm.*, July, 1889. Water distilled from it had neither taste nor odor, and was drunk by Vogel to the amount of six ounces without effect. When kept in a dry place, squill retains its virtues for a long time; but if exposed to moisture it soon becomes mouldy.

Uses.—Squill is expectorant, diuretic, and in large doses emetic and purgative. In overdoses it has been known to occasion hypercatharsis, strangury, bloody urine, and fatal inflammation of the stomach and bowels. The Greek physicians employed it as a medicine, and it has retained to the present period a deserved popularity. As an expectorant, it is used in cases both of deficient and of superabundant secretion from the bronchial mucous membrane,—in the former case usually combined with tartar emetic or ipecacuanha, in the latter frequently with the stimulant expectorants. In both instances it operates by stimulating the vessels of the lungs, and it should not be used when there is a high degree of inflammation, with arrested secretion. In *dropsy* it is much employed, especially in connection with digitalis, but, as it is distinctly irritant to the kidneys, it should not be used when there is irritation or active inflammation of these organs. On account of its great uncertainty and occasional harshness, it is very seldom prescribed as an emetic, except in *croup*, in which it is usually given in the form of syrup. When given in substance it is most conveniently administered in the form of pill.

From six to twelve grains (0.4 to 0.78 Gm.) will generally cause vomiting. The vinegar, fluidextract and syrup of squill are official, and are much used. An *acetic extract* has been prepared by F. D. Niblett, by digesting a pound of squill with three fluidounces of acetic acid and a pint of distilled water, with a gentle heat, for forty-eight hours, then expressing, and, without filtration, evaporating to a proper consistence. One grain is equal to about three grains of the powder. (*P. J.*, xii. 133.)

Dose, of squill, from one to two grains (0.065 to 0.13 Gm.).

SCOPARIUS. U. S. (Br.)

SCOPARIUS [Broom]

(scō-pā'ri-ūs)

"The dried tops of *Cytisus Scoparius* (Linné) Link (Fam. *Leguminosæ*)." *U. S.*
"The fresh and the dried tops of *Cytisus Scoparius*, Link." *Br.*

Scopari, *Cacumina*, *Br.*; Broom Tops; Herba Scopari, Spartium; Irish or Scotch Broom, Besom, Genêt à balais, *Fr.*; Gemeine Besenginster, Besenginster, Besenkraut, Pfrleimenkraut, *G.*

Cytisus Scoparius (L.), Link, *Enum. Hort. Berol.* (1822), 241.—*Spartium scoparium*, L., *Sp. Pl.* (1753) 709.—*Sarothamnus scoparius*, Wimm., Koch, *Syn. Fl. Germ. et Helv.* (1837), 152.—This is a common European shrub, cultivated in our gardens, from three to eight feet high, with numerous straight, pentangular, bright green, very flexible branches, and small, oblong, downy leaves, usually ternate, but on the upper part of the plant sometimes simple. The flowers are numerous, papilionaceous, large, showy, of a golden-yellow color, and solitary upon short axillary peduncles. The seeds are contained in a compressed legume, which is hairy at the sutures. It is essential that true broom be carefully distinguished from *Spanish broom* (*Spartium Junceum*), since a number of cases of poisoning have occurred from the substitution of the dried flowers of *Spartium* for those of broom. (See PART II.)

The whole plant has a bitter, nauseous taste, and, when bruised, a strong, peculiar odor. The tops of the branches are the official portion. They are in "thin, flexible, branched twigs, 2 to 3 Mm. thick; externally dark green, with five wings and numerous reddish-brown cork patches; internally yellowish; younger branches somewhat pubescent; fracture short-fibrous, that of thick pieces tough and splintery; usually free from the simple, obovate leaves; having a peculiar odor when bruised; taste disagreeably bitter." *U. S.* The seeds are reported to be used sometimes, and to be as active as the tops. Water and alcohol extract their active properties. According to Cadet de Gassicourt the flowers contain volatile oil, fatty matter, wax, chlorophyll, yellow coloring matter, tannin, a sweet substance, mucilage, albumen, and lignin. Stenhouse has separated from them two principles, *scoparin*, $C_{21}H_{32}O_{10}$,¹ and an alkaloid, *sparteine*, $C_{15}H_{26}Na$. The former is in stellate crystals, easily dissolved by boiling water and alcohol, and is obtained by purifying a yellow gelatinous substance deposited upon the evaporation of the decoction. It is only slightly soluble in cold water, more readily in hot water with greenish light yellow color, easily soluble in aqueous ammonia and caustic and carbonated alkalies. It is decomposed by heat. When fused with potassium hydroxide

¹ Goldschmidt and Himmelmayr (*Ap. Ztg.*, 1893, 566) give the following formula for scoparin: $C_{21}H_{32}O_{10}(OH)(OCH_3)$.

it yields, according to Hlasiwetz, phloroglucin and protocatechuic acid. Sparteine was obtained by distillation from the mother waters of the scoparin. It is a colorless liquid, having a peculiar bitter taste, and all the properties of a volatile alkaloid. It is heavier than water, and boils at 288° C. if distilled in a current of hydrogen gas. It dissolves only slightly in water, but takes up some water itself. In contact with water it becomes opalescent. It turns yellowish on distillation in air, but can be distilled colorless in an atmosphere of carbon dioxide. It is colorless, but becomes brown by exposure to light; it has at first an odor of aniline, but this is altered by rectification. It readily neutralizes acids and forms crystallizable salts, which are extremely bitter. Its sulphate occurs in colorless crystals, and is freely soluble in water. (See *P. J.*, June 28, 1879; also *Sparteina Sulphas*.) By the action of potassium dichromate and sulphuric acid, *oxysparteine*,¹ $C_{15}H_{24}N_2O$, is formed, and by the action of hydrogen dioxide upon this, a deliquescent *trioxysparteine*, $C_{15}H_{24}N_2O_3$, is obtained; if the hydrogen dioxide acts upon sparteine itself, *dioxysparteine*, $C_{15}H_{24}N_2O_2$, is formed as a solid, crystallizing in prisms melting at 128.5° C. Zinc and hydrochloric acid reduce sparteine to *hydrosparteine*, $C_{15}H_{28}N_2$, a thick liquid boiling at from 281° to 284° C. (Schmidt, *Pharmaceutische Chemie*, 3te Auf., Bd. ii. 1276.)

Uses.—Scoparius is diuretic and cathartic, and in large doses emetic, and has been employed with great advantage in *dropsy*, for which it was recommended by Meade, Cullen, and others. Cullen prescribed it in the form of decoction, made by boiling half an ounce of the fresh tops in a pint of water down to half a pint, of which he gave a fluidounce (30 Cc.) every hour until it operated by stool or urine. The seeds may be given in powder, in the dose of from ten to fifteen grains (0.65 to 1.0 Gm.). A fluidextract was official in the U. S. P. 1890. (See page 525.)

Scoparin probably represents the diuretic and purgative influences of scoparius, although its physiological and therapeutic properties have not as yet been sufficiently investigated. Poisonous doses of *sparteine* (see *Sparteina Sulphas*) cause in the lower animals tremblings, incoordination, increase of reflexes, clonic and tonic convulsions, embarrassment of the respiration, acceleration of the pulse, and enfeeblement of the heart, followed by gradual

enfeeblement of all the functions, convulsions, and death from asphyxia. Sparteine paralyzes the respiratory centres and the motor centres of the spinal cord, and has a very feeble influence upon the muscles, lessening, though not destroying, their excitability. Laborde was the first to call attention to its action upon the heart, and his results have been confirmed by Griffe, Garand, and Masius. Under the influence of the alkaloid there is a very great increase in the size and height of the cardiac wave. If the dose has been a small one, the pulse will be at first accelerated. After larger doses there is a slowing of the pulse. Observers agree in stating that the arterial pressure is not materially changed unless the dose is toxic, when it steadily falls; but small doses weaken and larger ones paralyze the peripheral pneumogastric nerve. Upon the vasomotor system sparteine appears to have no influence unless in large toxic doses, when it perhaps acts as a paralyzant. It does not represent the diuretic influence of scoparius. Sée affirms as the result of personal experience that sparteine is of very great value in *cardiac affections*, increasing the force of the cardiac beat, and especially producing regularity in cases of irregular cardiac action. For the latter purpose, he states, it is the most powerful remedy known. Other clinicians have recorded experience favorable to the value of sparteine, but the conclusion of Hiero Stoessel, that sparteine is inferior as a heart tonic to digitalis, and to be employed only as a succedaneum to that drug, probably indicates correctly the scope of its use. It has the great advantage of acting very quickly, the symptoms commencing about twenty minutes after its absorption, and reaching their maximum in four or five hours, but persisting one or two days. It is probably not safe to commence with doses greater than one-sixth of a grain (0.010 Gm.), although observers seem to be in accord in believing that much larger amounts are usually necessary. Voigt, Prior, Sée, and Leo all advise doses of one and a half grains (0.097 Gm.) repeated four or five times in the twenty-four hours. It is affirmed that no cumulative effects need be feared.

As the result of experiments upon the lower animals, Langlois and Maurange (*A. de P.*, vii. 1895) believe that sparteine and oxysparteine are valuable remedies for the maintenance of cardiac action during chloroformization, acting partly by stimulating the heart, partly by depressing the pneumogastric nerve. G. G. Cottam asserts (*T. G.*, Nov. 1896), as the result of a clinical study, that one-tenth grain of the sparteine sulphate, given hypodermically just before the inhalation of chloroform, will prevent any cardiac depression from the anæsthetic.

Dose, of scoparius, ten to fifteen grains (0.65 to 1.0 Gm.).

Off. Prep.—Infusum Scoparii, Br.; Succus Scoparii, Br.

¹ *Oxysparteine*, $C_{15}H_{24}N_2O$.—This is an alkaloidal oxidation product of sparteine, originally described by F. Ahrens (*Ber. d. Chem. Ges.*, 1891). It occurs in white, somewhat hygroscopic needles, melting at about 84° C., soluble in water, alcohol, ether, and chloroform. It has been found by Hurtle (*A. B. P. P.*, 1892) to be a cardiac stimulant, decreasing the pulse rate, but markedly increasing the arterial pressure and heart work. The hydrochloride, which occurs in large needles (often consolidated together) and is very soluble in water, has been used hypodermically by von Oefele in cases of *heart failure*. The dose is half a grain (0.032 Gm.), rapidly increased to one and a half grains (0.096 Gm.). The system is said soon to become accustomed to it.

SCOPOLA. U. S.

SCOPOLA

(scop-pō'la)

"The dried rhizome of *Scopola Carniolica* Jacquin (Fam. *Solanaceæ*), yielding, when assayed as directed below, not less than 0.5 percent. of its alkaloids." U. S.

Belladonna Scopola. Scopola Belladonna, Japanese Belladonna (incorrectly).

In 1771, John Anthony Scopoli, of the University of Pavia, described in the *Flora Carniolica* an *Atropa* from Idria. Three years later, Jacquin made this plant the type of the new genus *Scopola*, and gave it the specific name of *Carniolica*. Of this plant Koch made two species, one with green and the other with purple flowers, but the more recent botanists are in accord in believing that the green-flowered plant, the *S. hladnikiana* of Koch, the *S. viridiflora* of Rabenhorst, is not specifically distinct, there being, indeed, three varieties of *S. Carniolica*, one with purple, one with green, and one with yellow flowers, the latter being the *S. concolor* of De Candolle; indeed, E. M. Holmes has shown that the root examined by Schmidt was probably from a plant with yellow flowers, and therefore the *concolor* of De Candolle. *Scopolia atropoides* has also been described by Nevinny. (*Ph. Post*, 1894, 333, 349, 357.) See also Rusby's papers (*Proc. A. Ph. A.*, 1899, 292 and 1901, 313).

The genus *Scopola* is the connecting link between *Atropa* and *Hyoscyamus*, resembling *Atropa* in leaf and flower and in the microscopical character of its rhizome, but differing in that its fruit is not a berry and in the inflation of its calyx. The Japanese plant, *S. japonica*, is so closely allied to *S. carniolica* that its specific distinction is very doubtful; it has been separated upon the characters of the style being curved, the calyx-teeth unequal and the leaves less obovate and having much longer petioles than *S. Carniolica*; but Holmes has shown that the curved style occurs in *S. Carniolica*. *S. Carniolica* is a common plant in Bavaria, Austro-Hungary, and Southwestern Russia, usually in the hilly districts, where it grows in damp, stony places. Its general appearance is that of the belladonna, but it is much shorter, rarely growing above a foot in height, has thinner leaves, and is especially distinguished by its fruit being a transversely dehiscent capsule and by the presence of a distinct rhizome.

Properties.—The latter occurs in commerce either entire or longitudinally split in half, in pieces from two to five inches in length and from one-third to three-fourths or even one inch in diameter; of a grayish-brown color, very irregular in shape, often much bent or twisted, the whole surface usually covered thickly with the broad, subcircular, deeply-hollowed-out, projecting scars of the stems of successive seasons, and finely and coarsely wrinkled longi-

tudinally and transversely. The section is whitish and distinctly starchy in appearance. The texture is hard, but somewhat brittle. The taste is slightly bitter, and disagreeable. It is officially described as "of horizontal growth, more or less curved and shortly and sharply flexuous, cylindraceous and somewhat flattened vertically, occurring mostly in pieces from 2.5 to 7.5 Cm. long and 0.8 to 1.6 Cm. broad, often split before drying; upper surface marked with closely set, large, cup-shaped stem scars, margins irregularly contracted; externally varying from yellowish-brown to dark brownish-gray, finely and irregularly wrinkled longitudinally, obscurely annulate and more or less nodular-roughened; fracture short and sharp, exhibiting a yellowish-white bark, its corky layer dark brown, or pale brown, wood indistinctly radiate, and central pith rather horny; nearly inodorous; taste sweetish, afterwards bitterish and strongly acid." U. S.

The Japanese rhizome is from two to six inches long, about one-half inch in diameter, rarely branched, cylindrical or slightly compressed, knotty, bent, with circular disk-like scars, of a pale brown color, not whitish when abraded, with a slightly mousy, narcotic odor, and a taste nearly free from bitterness. According to Thos. Greenish, the microscopical characteristics of the rhizome of *S. Carniolica* are very similar to those of belladonna root, the chief differences being that the bark is less thick, the dark line under the epidermis narrower, the vascular bundles neither so large nor so numerous, and the bundles of raphides less pronounced; the starch grains are also smaller and their shape less distinct. The structure of the rhizome of *S. japonica* was found to be the same as that of the European species.

The alkaloid scopalamine (or scopoleine), $C_{17}H_{21}NO_4$, has been found to be the characteristic constituent of the root, but is also found in small quantities in belladonna root, stramonium seeds, and *Duboisia myoporoides*. E. Schmidt considers scopalamine to be identical with hyoscyne. (*A. Pharm.*, 1892, 206 to 232.) Scopalamine forms permanent transparent crystals of the formula $C_{17}H_{21}NO_4 + H_2O$, melting at $59^\circ C.$ to a colorless liquid. The double gold chloride melts at from 212° to $214^\circ C.$ Scopalamine is decomposed by baryta into scopoline, $C_8H_{13}NO_2$, a crystalline base, melting at $110^\circ C.$, and atropic acid, $C_8H_9O_2$. Commercial hyoscyne hydrobromide is said by E. Schmidt often to consist almost entirely of scopalamine hydrobromide, and Hesse has considered the two bases as identical. (*A. Pharm.*, 1894, 409.) O. Hesse examined commercial scopalamine hydrochloride, and found it to consist of salts of two bases, *hyoscyne* and *atropine*. (*P. J.*, 1896, 296.) Schmidt, continuing his investigations, proves that hyoscyne is a mixture of scopalamine and some other body, and believes Hesse's atropine to be opti-

cally inactive scopolamine. He doubts the existence of hyosine as a distinct body. (*Ap. Ztg.*, 1896.) Seward W. Williams states, as the result of the assay of many tons of the root of *Atropa belladonna* and of the rhizome of *Scopola*, each of the best qualities occurring in the American market, that while the belladonna root yields on an average 0.50 per cent. of alkaloid, the scopola yields 0.58 per cent. See also *Proc. A. Ph. A.*, 1899, 285.

Assay.—"The method to be employed is identical with that given for Belladonna Leaves, on page 228, using *ten grammes* of Scopola, in No. 60 powder." *U. S.*

Uses.—The physiological and medicinal properties of scopola are very similar to those of belladonna, but the crude drug has been scarcely used at all in medicine. It has been largely employed in America in the manufacture of belladonna plaster and much of the hyosine of commerce in the last decade has been obtained from it. Its alkaloid *Scopolamine hydrobromide* is recognized in the United States Pharmacopœia as identical with hyosine hydrobromide.

Dose, one to two grains (0.065 to 0.13 Gm.).

SCUTELLARIA. U. S.

SCUTELLARIA [Skullcap]

(scū-tēl-lā'rī-q)

"The dried plant of *Scutellaria lateriflora* Linné (Fam. *Labiatae*)."
U. S.

Skullcap, Hoodwort, Madweed, Mad-dog or Side-flowering Skullcap, Blue Pimpernel, Hooded Willow-herb; Scutellaire, *Fr.*; Helmkraut, Schildkraut, *G.*

Several species of *Scutellaria* have attracted attention. *Scutellaria galericulata*, L., or com-

mon *European skullcap*, which also grows wild in this country, has a feeble, somewhat alliaceous odor, and a bitterish taste. It has been employed in intermittents, and externally in old ulcers. The indigenous species, *S. integrifolia*, L. (syn. *S. hyssopifolia*, L.), is intensely bitter, and might probably be found useful as a tonic.

Scutellaria lateriflora, L., *Sp. Pl.* (1753) 598.—This is an indigenous perennial herb, with a stem erect, much branched, quadrangular, smooth, and one or two feet high. The leaves are ovate, acute, dentate, subcordate upon the stem, opposite, and supported upon long petioles. The flowers are small, of a pale blue color, and disposed in long, lateral, leafy racemes. The tube of the corolla is elongated, the upper lip concave and entire, the lower three-lobed. The plant grows in moist places by the sides of ditches and ponds in the United States and Canada.

Properties.—The dried tops are officially described as "about 50 Cm. long, smooth; stem quadrangular, branched; leaves opposite, petiole, about 5 Cm. long, ovate-lanceolate or ovate-oblong, serrate; flowers about 6 Mm. long, in axillary one-sided racemes, with a pale blue corolla and bilabiate calyx, closed in fruit, the upper lip helmet-shaped; odor slight; taste bitterish." *U. S.* H. Molisch and G. Goldschmidt (*Ph. Ztg.*, Dec. 4, 1901, 965) obtained from *Scutellaria* and a number of other labiates an identical body, to which they gave the name *scutellarin*. It is present in all of the different *Scutellarias*, being most abundant in the upper epidermis of the leaf, but found also in the roots, stems and flowers of the plant. It was further obtained from the leaves of *Galeopsis Tetrahit*, L., and of *Teucrium Chamaedrys*, L. In *Scutellaria altissima*, L., the presence of cinnamic and fumaric acid could also be established. Scutellarin is obtained by boiling freshly gathered leaves for 15 minutes in ten times their weight of water, filtering the decoction and adding from 1 to 2 per cent. of hydrochloric acid, which causes an abundant precipitate of scutellarin. If precipitation is effected from the hot solution, the scutellarin separates in the form of light yellow crystals. The formula $\text{C}_{21}\text{H}_{10}\text{O}_{12}$ has been assigned to the crude scutellarin so obtained. Its alcoholic solution gives a red precipitate with lead acetate and an intense green color with ferric chloride, changing on heating to a red color if the reagent is not present in great excess; alcoholic potassium or sodium hydroxides, as also alkali acetates, produce reddish-yellow precipitates, which change on exposure to the air to a green. Baryta water has the same effect. The green color is produced immediately if an oxidizing agent, such as chlorine or bromine water, is added.

Uses.—Skullcap is as destitute of medicinal properties as a plant may well be, not even being aromatic. When taken internally, it produces no very obvious effects, and probably is of no remedial value, although at one time it

was esteemed as a remedy in *hydrophobia*. It has also been used in *neuralgia* and *convulsive affections*, *chorea*, *delirium tremens*, and *nervous exhaustion* from fatigue or over-excitement. (*A. J. P.*, xxiii. 370; *N. J. M. R.*, v; *M. S. Rep.*, 1870.)

Dose, thirty to ninety grains (2.0 to 5.8 Gm.).

SENEGA. U. S. (Br.)

SENEGA [*Senega Snakeroot*]

(sēn'ē-gā)

"The dried root of *Polygala Senega* Linné (*Fam. Polygalaceæ*)." U. S. "The dried root of *Polygala Senega*, Linn." Br.

Senega Radix, Br.; Rattlesnake Root, Mountain Flax, Senega or Seneca Root or Snakeroot, Radix Polygalæ Virginianæ; Polygala de Virginie, Fr. Cod.; Radix Senegæ, P. G.; Senegawurzel, Klapper-Schlangenzurzel, G.; Poligala Virginiana, It.; Poligala de Virginia (Raiz de), Sp.

Besides *P. Senega*, two other species have attracted some attention in Europe—*P. amara* and *P. vulgaris*—as remedies in chronic pectoral affections; but, as they are not natives of this country, and are never used by practitioners here, they do not merit particular notice.¹

Polygala Senega, L., *Sp. Pl.* (1753) 704; Willd., *Sp. Plant.* iii. 894; Bigelow, *Am. Med. Bot.*, ii. 97; Barton, *Med. Bot.*, ii. 111; B. & T. 29.—This unostentatious plant has a perennial branching root, from which several erect, simple, smooth, round, leafy stems annually rise, from nine inches to a foot in height. The stems are occasionally tinged with red or purple below, but are green near the top. The leaves are alternate or scattered, lanceolate, pointed, smooth, bright green on the upper surface, paler beneath, and sessile or supported on very short footstalks. The flowers are small and white, and form a close spike at the summit of the stem. The calyx is their most conspicuous part. It consists of five sepals, two of which are wing-shaped, white, and larger than the others. The corolla is small and closed. The capsules are small, much compressed, obcordate, two-valved and two-celled, with two oblong-ovate, blackish, hairy seeds, slightly longer than the lobes of the caruncle. In *P. alba*, Nutt., the seeds are silky and about twice the length of the caruncle lobes.

Polygala Senega extends over most of the United States and Southern Canada, east of the Rocky Mountains. At one time it was largely collected in Canada and the Northeastern Atlantic states; when this supply was exhausted, Kentucky and the States West and

Southwest of it were invaded; then Wisconsin and the Northwestern States, from which with Western Canada the commerce at present derives its chief supply. There are two varieties of the plant, the typical *P. Senega*, the form found in the Northeastern United States, and the variety *latifolia*, which extends from Maryland and Pennsylvania to Michigan and Tennessee. This variety is distinguished by its height (from ten to twenty inches) and its very large, ovate or ovate-lanceolate leaves, which taper towards each end and attain a length of four inches. The root of commerce seems to be obtained from both varieties. It is brought into market in bales weighing from fifty to four hundred pounds.

Properties.—As the root occurs in commerce, it is of various sizes, from that of a straw to that of the little finger, presenting a thick knotty head, which exhibits traces of the numerous stems. It is tapering, branched, variously twisted, often marked with crowded annular protuberances, and with a projecting keel-like line, extending along its whole length. It is officially described as "somewhat cylindrical, tapering, more or less flexuous, 3 to 15 Cm. long and 2 to 8 Mm. thick, bearing several similar, horizontal branches and a few rootlets; crown knotty with numerous buds and short stem-remnants; externally yellowish-gray or brownish-yellow, longitudinally wrinkled, usually marked by a keel which is more prominent in perfectly dry roots near the crown; fracture short, wood light yellow, usually excentrically developed; odor slight, nauseating; taste sweetish, afterwards acid." U. S. The epidermis is corrugated, transversely cracked, of a yellowish-brown color in the young roots, and brownish gray in the old. In the smaller branches the color is a lighter yellow. The bark is thick, hard, and resinous, and whitish in its interior; it contains the active principles of the root. The central portion is ligneous, white, and quite inert, and should be rejected in the preparation of the powder. The color of this is gray. On microscopic examination the bark is seen to be composed of—1st, an outer layer, composed of a series of tubular cells; 2d, a middle layer of thin-walled, parenchymatous cells; 3d, an inner layer containing bast-cells. The keel is produced by the excessive development of this last layer of bark upon one side. There is no medulla. The odor of senega is peculiar, strong in the fresh root, but faint in the dried. The taste is at first sweetish and mucilaginous, but after chewing becomes somewhat pungent and acid, leaving a peculiar irritating sensation in the fauces. Senega root varies somewhat in appearance according to the locality from which it is derived, and local varieties are recognized in commerce. In *Southern senega* the roots are very small, while in *Manitoba senega* they are large and thick, dark in color, and often have purple markings about the crown. The official senega is often known

¹A senega which was first used in Japan, and which has been referred by some writers to *P. japonica*, by others to *P. tenuifolia*, has been examined by Reuter, who finds in it 0.8 per cent. of resin, traces of methyl salicylate, and 8.8 per cent. of an oil which has somewhat the odor of patchouli.

in commerce as *Southern senega*, or *small senega*, the roots seldom attaining the size of an ordinary lead-pencil, and four to five hundred of the dried roots being required to make a pound.

Between the years 1870 and 1880 the so-called *Northern*, the *White*, the *False*, or the *Large senega* was sent into the American market from Wisconsin, Minnesota, and further west. It is much larger than true senega, probably eighty to one hundred to the pound. The knot at the top of the root is from one to three inches in diameter; below it the root abruptly contracts to from half an inch to an inch in diameter; it is usually from eight to ten inches long, more fleshy and much less contorted than true senega, nearly free from small rootlets, but breaking up below into from four to eight descending branches; very light-colored, with the ligneous portion thick and regular, and in the circular outlines of the section, with the keel rudimental or not rarely altogether absent. The taste is similar to that of true senega, but somewhat more mucilaginous and less rapidly acid. In structure, false senega root is very similar to the true root; it has, indeed, been asserted that there are anatomical differences between the two senegas, but O. Linde (*P. J.*, xvi. 724) has been unable to make out any such differences. According to L. E. Sayre (*A. J. P.*, Sept. 1897), it is not possible to distinguish the two drugs when powdered. For description of the roots of a number of species of *Polygala*, see *Flora*, Jan. 1886, and *D. C.*, 1901, 26. False Senega was thought to be the product of *Polygala Boykinii*, Nuttall, but it appears to be well established that it is obtained from *P. alba*, Nuttall, whose habitat extends from the mountains of Texas to western British America. The properties of senega as well as the medicinal virtues of the root, are extracted by boiling water and by alcohol. Diluted alcohol is an excellent solvent.

Senega root was analyzed by Gehlen, Peschier of Geneva, Feneulle of Cambray, Dulon d'Astafort, Folchi, and Trommsdorff, and subsequently by Quevenne. The virtues of senega appear to reside chiefly, if not exclusively, in the acid principles called *senegin* and *polygalic acid*. These principles resemble saponin very closely and are recognized as distinct. Quevenne obtained polygalic acid by the following process. Powdered senega is exhausted by alcohol of 33°, and so much of the alcohol is distilled off as to bring the resulting tincture to the consistence of syrup. The residue is treated with ether in order to remove the fatty matter. The liquid upon standing deposits a precipitate, which is separated by filtration and is then mixed with water. To the turbid solution thus formed alcohol is added, which facilitates the production of a white precipitate, consisting chiefly of polygalic acid. The liquid is allowed to stand for several days, that the precipitate may be fully formed. The supernatant liquid being

decanted, the precipitate is drained upon a filter, and, being removed while yet moist, is dissolved by the aid of heat in alcohol of 36°. The solution is boiled with purified animal charcoal, and filtered while hot. Upon cooling, it deposits the principle in question in a state of purity. Thus obtained, polygalic acid is a white powder, inodorous, and of a taste at first slight, but soon becoming pungent and acrid, and producing a very painful sensation in the throat. It is fixed, unalterable in the air, inflammable, soluble in water slowly when cold and rapidly with the aid of heat, soluble in all proportions in boiling absolute alcohol, which deposits most of it on cooling, quite insoluble in ether and in the fixed and volatile oils, and possessed of the properties of reddening litmus and neutralizing the alkalies. Quevenne found it, when given to dogs, to occasion vomiting, and much embarrassment in respiration, and in large quantities to destroy life. Dissection exhibited evidences of inflammation of the lungs, and frothy mucus was found in the stomach, œsophagus, and superior portion of the trachea, showing the tendency of this substance to increase the mucous secretion, and explaining in part the beneficial influence of senega in croup. (*J. P. C.*, xxii. 449, and xxiii. 227.) Bolley showed that the active principle was resolvable by hydrochloric acid into glucose and a peculiar substance called *sapogenin*. Rochleder (*Chem. Cb.*, 1867, p. 925) confirmed this view of the identity of polygalic acid and saponin. Later investigators assert the existence of two homologous principles in the senega root,—*senegin*, $C_{17}H_{28}O_{10}$, and *polygalic acid*, $C_{18}H_{30}O_{10}$. That this latter is a variety of saponin is no doubt true. Christophson (*J. P. C.*, 1874) and Schneider (*A. Pharm.* [3], 7, 394) have also thoroughly established the existence of saponin in senega root. According to the researches of Trommsdorff and Schneider, saponin is contained solely in the bark, the woody tissues being inert. (See *Quillaja*, p. 1035.) L. Reuter (*A. Pharm.*, 1889, 309 and 452) finds that the constituents of senega root are fixed oil and resin, traces of volatile oil (a mixture of valeric ether and methyl salicylate), sugar (7 per cent.), senegin or saponin (from 2 to 5 per cent.), yellow coloring matter, and malates. The quantity of methyl salicylate¹ varied in different samples from 0.25 to 0.33 per cent. See also Schroeder's analysis (*A. J. P.*, 1896, 178). Kain (*Ph. Ztg.*, 1898, 562) states that he has discovered a lævo-rotatory glucoside distinguished from saponin by its mild taste, solubility in absolute alcohol, and in its not giving a precipitate with barium hydroxide.

Senega yields its virtues to water, cold or hot, and to boiling alcohol, and the extracts obtained by means of these liquids have the sensible properties of the root. But under the

¹ Methyl salicylate occurs in very many, if not all, of the species of the genus *Polygala*. (See paper by Kremers and James, *Ph. Rev.*, xvi.)

influence of heat a portion of the acrid principle unites with the coloring matter and coagulated albumen, and thus becomes insoluble in water. In forming an aqueous extract, the infusion should be prepared by percolation, as it is thus most concentrated, and consequently requires less heat in its evaporation. In preparing the infusion, the temperature of the water should not exceed 104° F. Experience has thoroughly proved the value of the use of an alkali in small proportion in making galenical preparations of senega, it prevents gelatinization and combines with the active principles (see *Fluidextractum Senegæ*, page 561).

The roots of *Panax quinquefolius*, L., or ginseng, were at one period frequently mixed with those of senega, but are easily distinguishable by their shape and taste. The roots of *Gillenla trifoliata* (L.), Moench., and *Asclepias Vincetoxicum*, L. (P. J., ix. 411), and of *Triosteum perfoliatum*, L. (see PART II), are noted as occurring in commercial senega; they are readily detected by the absence of the keel-like line.

Uses.—When given in overdose, senega is capable of acting as an irritant poison, producing violent vomiting and purging. Although other medicinal properties have been attributed to it, for many years it has been employed in medicine solely as a *stimulant expectorant*, useful in the advanced stages of an *acute bronchitis* attended with free expectoration; in *chronic bronchitis*, and in *asthma* and other diseases with catarrhal inflammation of the pulmonary mucous membrane. Polygalic acid may be employed in the dose of from the fourth of a grain to a grain (0.016 to 0.065 Gm.), and may be administered either in pill, capsule, or mixture. For a formula for its preparation, see also *A. J. P.*, 1860, 150.

Dose, from fifteen to twenty grains (1.0 to 1.3 Gm.).

Off. Prep.—*Infusum Senegæ*, Br.; *Fluidextractum Senegæ*, U. S.; *Liquor Senegæ Concentratus*, Br.; *Syrupus Senegæ*, U. S. (from *fluidextract*); *Tinctura Senegæ*, Br.

SENNA. U. S. (Br.)

SENNA

(sē'nə)

"The dried leaflets of *Cassia acutifolia* Delile (Alexandria Senna), or of *Cassia angustifolia* Vahl (India Senna) (Fam. Leguminosæ)." U. S. SENNA ALEXANDRINA. *Alexandrian Senna*, Br. "The dried leaflets of *Cassia acutifolia*, Delile." Br. SENNA INDICA. *East Indian Senna* (syn. *Tinnevely Senna*). "The dried leaflets of *Cassia angustifolia*, Vahl." From plants cultivated in Southern India." Br.

Senna Alexandrina, *Senna Indica*, Br.; *Senna Leaves*; *Séné*, Fr. *Cod.*; *Feuilles de Séné*, Fr.; *Folia Sennæ*, P. G.; *Sennesblätter*, G.; *Sena*, It.; *Sen*, Sp.

The plants which yield senna belong to the genus *Cassia*, of which several species con-

tribute to furnish the drug. These were confounded by Linnæus and comprised in a single species, which he named *Cassia Senna*. Since his time the subject has been more thoroughly investigated, especially by Delile, who accompanied the French expedition to Egypt and had an opportunity of examining the plant in its native country. Besides the official species, it is probable that *C. lanceolata* of Forskhal and *C. aethiopica* of Guibourt contribute towards commercial senna. The leaves of a number of species of *Cassia* are utilized like senna leaves in the respective countries in which they grow, among which may be mentioned *C. marylandica*, L.; *C. cathartica*, Mart.; *C. rugosa*, Don; *C. splendida*, Vog.; *C. lævigata*, Willd.; *C. multijuga*, Rich.; *C. Chamæcrista*, L.; and *C. montana*, Hayne.

Cassia acutifolia, Delile, *Flore d'Égypte* (1812), 219.—*C. Senna*, Linn., *Sp. Pl.* 377.—*C. lanceolata*, Collad., *Hist. Cass.* 93, t. 15.—*C. lenitiva*, Bisch., *Bot. Zeit.* (1850) 885.—*Senna acutifolia*, Batka, *Proc. Linn. Soc.* (1854), 282. This is described as a small undershrub, two or three feet high, with a straight, woody, branching, whitish stem; but, according to Landerer, the senna plant attains the height of eight or ten feet in the African deserts. The leaves are alternate and pinnate, with glandless footstalks, and two small narrow pointed stipules at the base. The leaflets, of which from four to six pairs belong to each leaf, are almost sessile, oval-lanceolate, acute, oblique at their base, nerved, from half an inch to an inch long, and of a yellowish-green color. The flowers are yellow, and in axillary spikes. The fruit is a flat, elliptical, obtuse, membranous, smooth, grayish-brown, bivalvular legume, about an inch long and half an inch broad, scarcely if at all curved, and divided into six or seven cells, each containing a hard, heart-shaped, ash-colored seed. *C. acutifolia* grows wild in great abundance in Upper Egypt, Nubia, Sennaar, and other parts of Africa. This species furnishes the greater part of the variety known in commerce by the name of Alexandria senna.

Cassia angustifolia, Vahl, *Symb. Bot.* i. 29. *C. elongata*, Lemaire, *J. P. C.* (1821), 345; Fée, *Journ. de Chim. Méd.*, vi. 232; Carson, *Illustr. of Med. Bot.*, i. 36, pl. 29.—The name *C. elongata* was conferred by Lemaire upon the plant from which the India senna of commerce is derived, but the U. S. and Br. Pharmacopœias unite in ascribing the source to *C. angustifolia*, Vahl. The botanical description was completed by Fée from dried specimens of the leaves and fruit found by him in unassorted parcels of this variety of senna. Wallich afterwards succeeded in raising the plant from seeds found in a parcel of senna taken to Calcutta from Arabia, and it has been described by Royle, Wight and Arnott, and Lindley. As usually grown, it is annual, but with care it may be made to live through the year, and then assumes the character of an undershrub. It has

an erect, smooth stem, and pinnate leaves, with from four to eight pairs of leaflets. These are nearly sessile, lanceolate, obscurely mucronate, oblique at the base, smooth above and somewhat downy beneath, with the veins turned inward so as to form a wavy line immediately within the edge of the leaflet. The most striking character of the leaflet is its length, which varies from an inch to twenty lines. The petioles are without glands; the stipules minute, spreading and semi-hastate. The flowers are bright yellow, and arranged in axillary and terminal racemes rather longer than the leaves. The legume is oblong, membranous, tapering abruptly at the base, rounded at the apex, and an inch and a half long by somewhat more than half an inch broad. This plant is found in Southern Arabia and on the coast of East Africa from Mozambique to the Somali land. It has been said to grow in the interior of India, and is cultivated at Tinnevely for medicinal use.

Cassia obovata, Colladon, *Hist. Cass.* 92, t. 15.—The stem of this species is rather shorter than that of *C. acutifolia*, rising to the height of only a foot and a half. The leaves have from five to seven pairs of leaflets, which are obovate, very obtuse, sometimes mucronate. The flowers are in axillary spikes, of which the peduncles are longer than the leaves of the plant. The legumes are very much compressed, curved almost into the kidney form, of a greenish-brown color, and covered with a very short down, which is perceptible only by the aid of a magnifying glass. They contain from eight to ten seeds. This species grows wild in Syria, Egypt, Senegambia, and Jamaica. (*P. J.*, Sept. 1867.) It has been cultivated successfully in Italy, Spain, and the West Indies. It is said to be no longer gathered for senna, although its leaflets and pods occur in Alexandria senna.

C. lanceolata of Forskhal (*Fl. Ægypt. Arab.*, 85; syn. *C. Sophora*, L., *Sp. Pl.* 379), found by that author growing in the deserts of Arabia, is admitted by Lindley and others as a distinct species. Some difference of opinion, however, exists upon this point. De Candolle considered it a variety of the *C. acutifolia* of Delile, from which it differs chiefly in having leaflets with glandular petioles, and, as Forskhal's description preceded that of Delile, he designated the species by the name of *C. lanceolata*. Forskhal's plant has been supposed by some to be the source of the India or Mocha senna, but the leaflets in this variety are much longer than those of *C. lanceolata*, from which the plant differs also in having no gland on the petiole. Niebuhr informs us that he found the Alexandria senna growing in the Arabian territory of Abu-Arîsch, whence it is taken by the Arabs to Mecca and Jeddah. This is probably the *C. lanceolata* of Forskhal. It is highly probable that this species is the source of a variety of senna which has been brought to this market under the name of *Mecca senna*.

Cassia æthiopica of Guibourt, *Hist. Drogues*, 3e éd., iii. 219 (*C. ovata* of Mérat), formerly confounded with *C. acutifolia*, is considered by Lindley to be a distinct species. It grows in Nubia, Fezzan, to the south of Tripoli, and probably, according to Guibourt, throughout Ethiopia. It is from this plant that the *Tripoli senna* of commerce is derived.

Several varieties of this valuable drug are known in commerce. Of these, four have been received in America,—the Alexandria, the Tripoli, the India, and the Mecca senna,—but only two are recognized by the Pharmacopœia.

1. ALEXANDRIA SENNA.—This variety of senna is gathered in extreme Upper Egypt and the Soudan, and thence sent to Assouan at the First Cataract of the Nile, whence it finds its way into commerce through Cairo, Suakim, Suez and Alexandria. As the Egyptian customs keep no especial statistics the quantity exported can only be judged by the fact that in 1902 one Cairo firm sent into commerce 400 tons of senna. Two crops are produced annually, one in the spring and one in the autumn. The plants are first cut, then dried, and then the stripped-off leaves and pods are packed in crude bales, in which several species of senna are represented in varying proportion, the predominating species being *C. acutifolia*. Formerly there was a purposive mixture of the product of *Cassia acutifolia* with the leaflets of *C. obovata*, brought from other parts of Egypt, and even from Syria, with the leaves of *Cynanchum oleafolium* (*C. Argel* of Delile, *Solenostemma Argel*, Hayne), known commonly by the name of *argel* or *arguel*, and sometimes with those of *Tephrosia apollinea* of De Candolle, a leguminous plant growing in Egypt and Nubia. According to M. Royer, the proportions in which the three chief constituents of this mixture were added together were five parts of *C. acutifolia*, three of *C. obovata*, and two of *Cynanchum*. Thus prepared, the senna was again packed in bales, and transmitted to Alexandria. But at present there is no such uniformity in the constitution of Alexandria senna, and, though the three chief ingredients may still sometimes be found in it, they are not in the same fixed proportions, and not unfrequently the *Cynanchum* leaves are wholly wanting. This variety of senna is often called in French pharmaceutical works *séné de la pathe*, a name derived from an impost formerly laid upon it by the Ottoman Porte. A parcel of Alexandria senna, as it was formerly brought to market, consisted of the following ingredients: 1, the leaflets of *C. acutifolia*, characterized by their acute form, and their length, almost always less than an inch; 2, the leaflets of *C. obovata*, known by their rounded very obtuse summit, which is sometimes furnished with a small projecting point, and by their gradual diminution in breadth towards their base; 3, the pods, broken leafstalks, flowers, and fine fragments of other parts of one or both of these species; 4, the leaves of

Cynanchum oleæfolium, which are distinguishable by their length, almost always more than an inch, their greater thickness and firmness, the absence of any visible lateral nerves on their under surface, their somewhat lighter color, and the regularity of their base. In this last character they strikingly differ from the genuine senna leaflets, which, from whatever species derived, are always marked by obliquity at their base, one side being inserted in the petiole at a point somewhat lower than the other, and at a different angle. Discrimination between this and the other ingredients is of some importance, as the *Cynanchum* must be considered an adulteration. It is said by the French writers to produce hypercatharsis and much irritation of the bowels, but was found by Christison and Mayer to occasion griping and protracted nausea, with little purgation. The flowers and fruit of the *Cynanchum* were also often present, the former white and in small corymbs, the latter an ovoid follicle rather larger than an orange-seed. Besides the above constituents of Alexandria senna, it occasionally contained leaflets of genuine senna, much longer than those of the *acutifolia* or *obovata*, equalling in this respect the *Cynanchum*, which they also somewhat resembled in form. They were distinguishable, however, by their greater thinness, the distinctness of their lateral nerves, and the irregularity of their base. The leaflets and fruit of *Tephrosia apollinea*, which have been an occasional impurity in this variety of senna, may be distinguished, the former by their downy surface, their obovate-oblong, emarginate shape, their parallel unbranched lateral nerves, and by being usually folded longitudinally; the latter, by its dimensions, being from an inch to an inch and a half long, and only two lines broad. As now imported, Alexandria senna is often quite free from the leaves of *Cynanchum*, and may have few or none of the leaflets of obovate senna. It is probably brought directly to Alexandria from Upper Egypt, without having undergone intermixture at Boulak or other intervening place. In Europe, this senna was formerly adulterated with the leaflets of *Colutea arborescens*, L., or bladder senna; and the leaves of *Coriaria myrtifolia*, L., a poisonous plant of Southern Europe. An account of these plants is given in PART II.

The leaflets of the *Coriaria* are ovate-lanceolate, grayish green with a bluish tint, and are readily known, when not too much broken up, by their strongly-marked midrib and two lateral nerves running from the base nearly to the summit. Another addition to Alexandria senna has been detected by Lacroix of Mâcon, France, in the leaves of the *Globularia Turbith* (*Globularia Alypum*, Linn.), which seem to have taken the place of the *Colutea arborescens*, because more closely resembling the senna leaflet. The leaves of the *Globularia* are spatulate, much enlarged towards the upper end, rounded at the extremity, but always terminating in a

short sharp point. Besides, they are brown, thick, firm, and hard to the touch, while those of the *Colutea* are green, very thin, and soft. They have an acrid, very bitter taste, but are without nauseous odor. They are asserted to be cathartic, but milder than senna, and capable of being substituted for it in twice the dose. (*J. P. C.*, 4e sér., i. 413.) The so-called *Aden senna* which Holmes states to be active, is composed of small, broad, not very acute, hairy leaves, and is believed to be obtained from *C. holosericea*, Fres. A false senna from Madras has been identified by E. M. Holmes as the product of *Cassia montana*, Hayne. The leaflets are about the size of the Tinnevely senna, but are distinguishable by obtuse or rounded ends furnished with distinct mucro, which is, however, often broken off and wanting from individual leaves; by the obtuse angles of the lateral veins and by the presence of a well marked network of veins of the under surface; further, the color of the upper surface is distinctly browner than of the Tinnevely leaflet, and the whole leaves of *Cassia montana* have from 10 to 15 pairs of leaflets, while the Tinnevely senna has only from 6 to 8 pairs. In the drug this character can usually be made out by noticing the number of scars on the rachis. For a microscopic description of powder, see H. G. Greenish, *P. J.*, 66, 694. In detecting the adulteration of senna, the apothecary may avail himself not only of the general physical characteristics of the leaves, but also of the fact that while the senna leaf, containing no tannic acid, does not precipitate ferric chloride, most leaves used in adulteration do alter the ferric solution. The microscopic characteristics of the false leaves, though varying greatly, are almost always very different from those of senna. In the senna leaflets the epidermis from the upper and under surface is very similar. The stomata are numerous; the epidermal hairs are unicellular and deciduous, leaving, when detached, a base which has the appearance of an annular pad, around which the neighboring cells seem to radiate. The parenchyma of the cell has a thick epidermis, and is divided into three layers, the uppermost and lowest of which consist of palisade tissue, and are separated by a zone of very small, rounded, parenchymatous cells. Stellate crystals of calcium oxalate are scattered throughout the parenchyma, and prismatic crystals, one in each cell, occur clustered around the bast tissue of the principal veins.

Alexandria Senna is officially described as "leaflets about 25 Mm. long and 10 Mm. broad, having extremely short, stout petioles; inequilaterally lanceolate or lance-ovate, acutely cuspidate, entire, subcoriaceous, brittle, pale green or grayish-green, sparsely and obscurely hairy, especially beneath, the hairs appressed, 1-celled, and thick-walled; odor characteristic; taste somewhat mucilaginous and bitterish." *U. S.* For a microscopical description of Alexandria senna, see *Proc. A. Ph. A.*, 1882, p. 238.

2. **TRIPOLI SENNA.**—Genuine Tripoli senna consists in general exclusively of the leaflets of one species of *Cassia*, formerly considered to be a variety of *C. acutifolia*, but now admitted to be distinct, and named *C. aethiopica*. The leaflets, however, are much broken up, and it is probably on this account that the variety is usually less esteemed than the Alexandrian. The aspect given to it by this state of comminution, and by the uniformity of its constitution, enables the eye at once to distinguish it from the other varieties of senna. The leaflets, moreover, are shorter, less acute, thinner, and more fragile than those of *C. acutifolia* in Alexandria senna, and their nerves are much less distinct. The general opinion at one time was that it was brought from Sennaar and Nubia to Tripoli in caravans; but, it is reasonably asked by Fée, how could it be afforded at a cheaper price than the Alexandrian, if thus brought on the backs of camels a distance of eight hundred leagues through the desert? It is probably collected at Fezzan, immediately south of Tripoli.

3. **INDIA SENNA.**—This variety is in Europe sometimes called *Mocha senna*, probably because obtained originally from that port. It derives its name of India senna from the route by which it reaches us. Though produced in Arabia, it is brought to this country and Europe from Calcutta, Bombay, and possibly other ports of Hindostan. It consists of the leaflets of *Cassia elongata*, with some of the leafstalks and pods intermixed. The eye is at once struck by the great length (about two inches) and comparative narrowness of the leaflets, so that the variety may be readily distinguished. The pike-like shape of the leaflet has given rise to the French name of *séné de la pique*. Many of the leaflets have a yellowish, dark-brown, or blackish color, probably from exposure after collection, and the variety has commonly in mass a characteristic dull tawny hue. It is generally considered inferior in purgative power. Leaflets of a senna resembling the Indian were brought by Livingstone from Southern Africa, where the plant grows abundantly. (*P. J.*, xvii. 499.) "Leaflets 25 to 50 Mm. long, 10 to 15 Mm. broad, inequilaterally lanceolate, entire, thin, more abruptly pointed than those of Alexandria Senna, yellowish-green, and smooth above, paler beneath; in odor and taste closely resembling Alexandria Senna. Senna should be free from stalks, and from Argel leaves, which are sometimes present in Alexandria Senna, and which are equilateral, 1-veined, thick, wrinkled, glaucous, and possess 3-celled hairs." *U. S.*

A variety of India senna has reached this country which is a product of Hindostan, being cultivated at Tinnevely, and probably other places in the south of the Peninsula. The plant was originally raised from seeds obtained from the Red Sea, and is the same as that from which the common Indian senna is derived. The drug is exported from Madras

to England, where it is known by the name of *Tinnevely senna*. It is a fine unmixed variety, consisting of unbroken leaflets, from one to two or more inches long, and sometimes half an inch in their greatest breadth, thin, flexible, and of a fine green color. T. B. Groves, however, states as the result of his experiments that Tinnevely senna contains only two-thirds as much of the active principle as does the Alexandrian. (*P. J.*, Oct. 1868, p. 292.)

4. **MECCA SENNA.**—After the publication of the fifth edition of this Dispensatory, a variety of senna was imported under the name of *Mecca senna*, consisting of the leaflets, pods, broken stems, and petioles of a single species of *Cassia*. The leaflets were oblong-lanceolate, on the average longer and narrower than those of *Cassia acutifolia*, and shorter than those of *Cassia elongata*. The variety in mass had a yellowish or tawny hue, more like that of India than like that of Alexandria senna. May it not have been the product of the *Cassia lanceolata* of Forskhal? We might infer so from the name, and from the character of the leaflet. Landerer, however, speaks of a valuable variety of senna, characterized by the large size of the leaflets, and sold under the name of *Mecca senna*, which he says comes from the interior of Africa.

Much study has been given to the question of distinguishing the powder of Alexandria and India senna by means of the microscope. (See papers by Sayre, *A. J. P.*, 1896, 1897; Schneider, *Am. Drug.*, 1897; Denniston, *Ph. Rev.*, vol. xvi.) As a result of these studies it is asserted that it is possible to take advantage of the greater hairiness of the Alexandria senna as a practical distinction, it being alleged that a piece of the epidermis of Alexandria leaf contains twice as many hairs as does a similar sized shred of epidermis from the India senna. It is especially proposed to count the number of epidermal cells between two hairs or their scars, the average distance of the hairs from one another being in the Alexandria senna three epidermal cells, and in the India six cells. Advantage may also be taken of the difference in the neighboring cells of the stomata; in the majority of stomata, in each case, there are two of the neighbor-cells, but in India senna the proportion is one having three neighbor-cells to seven having two, and in the Alexandria the proportion is one having three to two having two.

Commercial senna is prepared for use by *garbling*, or picking out the leaflets, and rejecting the leafstalks, the impurities, and the leaves of other plants. The pods are also rejected by some apothecaries. They were preferred by the Arabian and mediæval physicians of Europe to the leaves, while Pereira states that they are much milder in their operation than the leaflets. This has been explained by the researches of E. F. Salmon, who has found that they contain about 25 per cent. more cathartin than the leaves, but no resinous principle or

volatile oil. (*P. J.*, Oct. 1889.) The griping of senna being largely due to the resin, it is *a priori* to be expected that the pods would act more kindly than the leaves. A. W. Macfarlane has found this to be actually the case. From six to twelve pods for the adult, or from three to six for the young or very aged, infused in a claret-glass of cold water, in his experience, act very kindly but very thoroughly upon the whole intestine.

Properties.—The odor of senna is faint and sickly; the taste slightly bitter, sweetish, and nauseous. Water and diluted alcohol extract its active principles. Pure alcohol extracts them but imperfectly. (Bley and Diesel, *Ph. Cb.*, Feb. 1849, p. 126.) The leaves are said to yield about one-third of their weight to boiling water. The infusion is of a deep reddish-brown color, and has the odor and taste of the leaves. When exposed to the air for a short time, it deposits a yellowish insoluble precipitate, supposed to result from the union of extractive matter with oxygen. The nature of this precipitate, however, is not well understood. Decoction also produces some change in the principles of senna, by which its medicinal virtues have been supposed to be impaired, but some experiments of B. Heerlein would seem to show that this opinion is incorrect. An extract prepared by boiling down an infusion, redissolving the residue, and again boiling down to a solid consistence, was found to operate actively in a dose equivalent to a drachm of the leaves. (*Ph. Cb.*, 1851, p. 909.) To diluted alcohol it imparts the same reddish-brown color as to water, but rectified alcohol and ether, digested upon the powdered leaves, become of a deep olive-green.

Lassaigne and Feneulle first isolated a substance to which they gave the name of *cathartin*, but it proved to be a mixture; Bley and Diesel (*Ph. Cb.*, 1849, p. 126) isolated a yellow coloring matter, which they called *chrysoretin*, but which Martius identified as *chrysophan*; Ludwig (*A. Pharm.* (2), 119, p. 42, and 190, p. 69) obtained two bitter principles, *sennapicrin* and *sennacrol*, the first insoluble, the second soluble in ether; but the active purgative principle was first discovered in 1866 by Dragendorff and Kubly (*Viertelj. f. Prakt. Pharm.*, 16, pp. 96 and 337), who found it to be a glucoside of weak acid character, and named it *cathartic acid*. Thos B. Groves, in 1868 (*P. J.*, 1869, p. 196), unaware of Dragendorff and Kubly's discovery, isolated the same principle, and found for it the same reactions. For a method of preparing cathartic acid, by Ralph Stockman, see *P. J.*, 1885, p. 740. Its formula is given as $C_{18}O_8H_{26}Na_2SO_8$, and by boiling its alcoholic solution with acids it yields *cathartogenic acid* and sugar. Gensz (*A. J. P.*, 1893, 334), who prepared it later by the method of Kubly and Stockman, gave the formula $C_{30}H_{38}NO_{12}$. It is amorphous, difficultly soluble in cold water, readily soluble in boiling water. The best solvent is a 30 to 40

per cent. alcohol; ether, benzene, chloroform, and petroleum ether are without solvent action. Alkalies with heat decompose it. It is prepared by partially precipitating with alcohol infusion of senna, concentrating to a syrupy consistence *in vacuo*, filtering, treating the filtrate with a large proportion of absolute alcohol, and repeatedly dissolving in water, and precipitating by alcohol the precipitate thus obtained. It is purified by submitting it (dissolved in moderately strong hydrochloric acid) to dialysis on a diaphragm of parchment paper, cathartic acid having strong colloidal properties. Groves found that ammonium cathartate purged moderately in the dose of three and three-quarters grains, with considerable griping, and that of certain mixed cathartates seven and a half grains purged violently, with much griping and sickness, and continued to act through most of a day. He considers four grains a fair dose. It should be given in connection with an aromatic and a saline cathartic. *Magnesium cathartate* is soluble. The salts of this acid in aqueous solution are decomposed and rendered inert by long exposure to heat in contact with the air. (Groves, *P. J.*, Oct. 1868, 200-1.) Dragendorff and Kubly also found chrysophanic acid in small proportions, the two substances, *sennacrol* and *sennapicrin*, previously mentioned, and a peculiar non-fermentable saccharine principle, with the formula $C_{21}H_{44}O_{19}$, which they named *catharto-mannite*. (*J. P. C.*, 4e sér., v.) A. Seidel proposes the name of *sennit* for catharto-mannite, and gives a process for its preparation in *A. J. P.*, 1885. In 1900 Tschirch and Hiepe made a comprehensive investigation of the chemical constituents of senna. From the aqueous percolate they extracted, besides *cathartic acid*, a crystalline body, giving the same reactions as *sennanigrin* and having the composition $C_{14}H_{10}O_5$. From the weak ammoniacal percolate they obtained *anthraglucosennin*, which, however, is composed of several distinct substances, for on treating it with ether, a portion enters solution and another remains undissolved; then the ether-soluble portion, if boiled with toluene and the solution poured on petroleum benzin, precipitates *senna-emodin*, while *sennachrysophanic acid* remains in solution and may be obtained on evaporation; the portion insoluble in toluene is a body which the authors have named *glucosennin*. Its composition agrees with the formula $C_{22}H_{12}O_8$, and it is possibly an emodin glucoside. From the portion of anthraglucosennin insoluble in ether, *sennaismoemodin* is obtained by treatment with acetone and shaking the resultant solution with petroleum benzin. The acetone solution retains a substance which the authors have named *sennarhamnetin*. Finally, the portion of anthraglucosennin remaining undissolved after treatment with ether and acetone is a black body which resembles in this and other respects aloenigrin. *Sennanigrin*, however, yields on treatment with alco-

holie potassium hydroxide, sennaemodin and sennachrysophanic acid. (*A. Pharm.*, Aug 31, 1900, 427, 448.)

Some results of experiments on the properties of senna which more particularly concern the pharmacist are noted in a paper contained in the *J. P. C.* (Janv. 1874, p. 80), and require to be mentioned here, because they tend to fix certain points which are left undetermined in the above statement. An extract made by evaporating in the air an aqueous infusion of senna possesses but partially the purgative properties of the leaves. If the extract be redissolved in a large quantity of water, and the solution be again evaporated, the extract now obtained will be quite inert. It follows that a prolonged decoction of senna destroys its cathartic powers. The presence of an alkali in the decoction increases the rapidity of the destruction. An infusion of senna in lime water, heated to the boiling point, and then deprived of lime by a stream of carbon dioxide, becomes inert. An infusion of senna, made to boil after the addition of potassium hydroxide, and then neutralized by an acid, is also inert. The mineral acids destroy the purgative powers of senna, but less energetically than the alkalies; the vegetable acids exercise the same power but feebly. Concentrated alcohol does not dissolve the active principle, which is soluble in cold water. It was Heerlein who first determined the complete want of purgative power in the pure alcoholic extract of senna. Nevertheless, this extract possesses in a high degree the odor and taste of senna, and, taken internally, without purging, imparts a deep-yellow color to the urine, which the alkalies change to red. The leaves exhausted by alcohol have all their purgative effect, but lose the power of affecting the urine so that an alkaline solution shall color it red. These facts prove that chrysophanic acid is not the purgative principle of senna. The fact that alcohol removes the odor and taste of senna without affecting its purgative action may sometimes be advantageously applied in cases in which the taste of senna is extremely offensive. L. Siebold, after experimenting with senna leaves washed with alcohol, arrived at the following conclusions. 1. Strong spirit does not remove any of the active principle from senna leaves. 2. The therapeutic action of cathartic acid is assisted by one or more of the constituents yielded by senna to strong alcohol, though these constituents produce no purgative effect when taken alone. 3. Senna exhausted by alcohol is a reliable and pleasant purgative, but somewhat weaker in its action than the unexhausted leaves.¹

Incompatibles.—Many substances produce precipitates with the infusion of senna, but it does not follow that they are all medicinally incompatible, as they may remove only inert ingredients. Cathartic acid is precipitated by infusion of galls and solution of lead subacetate. Lead acetate and tartar emetic which disturb the infusion, have no effect upon the solution of this substance.

Uses.—Senna was first used as a medicine by the Arabians. It was noticed in their writings as early as the ninth century, and the name itself is Arabic. It is a prompt, efficient, and very safe purgative, well calculated for *fevers* and *febrile complaints*, and other cases in which a decided but not violent impression is desired. A disadvantage is that it is likely to produce griping. This effect, however, may be obviated by combining with the senna some aromatic, and some one of the alkaline salts, especially potassium bitartrate, potassium tartrate, or magnesium sulphate. The explanation which attributes the griping property to the oxidized extractive, and its prevention by the saline substances to their influence in promoting the solubility of that principle, is not satisfactory. The purgative effect of senna is considerably increased by combination with bitters,—a fact noticed by Cullen, and abundantly confirmed by subsequent experience. The decoction of guaiac is said to exert a similar influence. Senna yields one or more of its principles to the urine, as, from twenty to thirty minutes after it has been taken, this secretion acquires the property of being reddened by ammonia. (*J. P. C.*, Août, 1863.) Senna taken by nurses is said to purge sucking infants, and an infusion injected into the veins operates as a cathartic. The drug is never prescribed in powder. In official preparations “Tinnevely senna may be used in place of Alexandria senna.” *Br.* 1885. Dose of cathartic acid as a laxative, from three to six grains (0.2 to 0.4 Gm.).

Dose, of senna, one-half to two drachms (2.0 to 7.7 Gm.).

SERPENTARIA. U. S. (Br.)

SERPENTARIA [Virginia Snakeroot]

(sēr-pen-tā'ri-ā)

“The dried rhizome and roots of *Aristolochia Serpentaria* Linné (Virginia Serpentaria),

¹ *Vinum Sennæ, Senna Wine.*—Alexandria Senna Leaves, one and a half ounces; Sherry Wine, twenty-seven ounces. Macerate for eight days, press, and strain; then add five grains of Gelatin, dissolved in two and a half drachms of distilled water, and then the following: Tincture of Orange Peel, one ounce; Tincture of Ginger, a half-ounce; Aromatic Tinc-

ture, eighty minims; Honey, two ounces. Again allow to stand for ten days, and filter. This wine is reputed to be an excellent aperient for persons suffering from hemorrhoids. It should be taken in tablespoonfuls, according to the effect desired. (*Dieterich's Pharm. Manual.*)

or of *Aristolochia reticulata* Nuttall (Texas *Serpentaria*) (Fam. *Aristolochiaceæ*)." U. S. "The dried rhizome and roots of *Aristolochia* *Serpentaria*, Linn., or of *Aristolochia reticulata*, Nutt." Br. For *Aristolochia*, Br. Add., see PART II.

Serpentariæ Rhizoma, Br.; Serpentry Rhizome; *Radix Colubrina*, *Radix Viperina*; Serpentry, Sangre; Serpentry de Virginie, Fr. *Cod.*; Couleuvre de Virginie, Fr.; Virginische Schlangenzwurzel, G.

Many species of *Aristolochia* have been employed in medicine. The roots of all of them are tonic and stimulant, and their supposed possession of emmenagogue properties has given origin to the name of the genus. *A. Clematidis*, *A. longa*, *A. rotunda*, are still retained in official catalogues of the continent of Europe, where they are indigenous. *A. Pistolochia*, L., of Southern Europe appears to have been the *Aristolochia* of Pliny and is still used under the name of *Pistolochia*. The root of *A. Clematidis* is very long, cylindrical, as thick as a goose-quill or thicker, variously contorted, beset with the remains of the stems and radicles, of a grayish-brown color, a strong, peculiar odor, and an acrid, bitter taste; that of *A. longa*, L., is spindle-shaped, from a few inches to a foot in length, of the thickness of the thumb or thicker, fleshy, very brittle, grayish externally, brownish yellow within, bitter, and of a strong, disagreeable odor when fresh; that of *A. rotunda*, L., is tuberous, roundish, heavy, fleshy, brownish on the exterior, grayish-yellow internally, and similar to the preceding in odor and taste; that of *A. Pistolochia*, L., consists of numerous slender yellowish or brownish fibres, attached to a common head, and possessed of an agreeable aromatic odor, with a taste bitter and somewhat acrid. Many species of *Aristolochia*, growing in the West Indies and Southern America, have been used medicinally. *A. cymbifera*, Martius, known in Brazil as *mihommen*, *jarra*, *jarrinha*, and in Mexico as *guaco*, is said to have medicinal properties similar to those of the official species, but Butte affirms that it is depressant to the sensory nerve centres and useful in *neuralgia* and *pruritus*. In the Argentine Republic¹ the root of *A. argentina* is used as a diuretic and diaphoretic, especially in *rheumatism*. In the East Indies *A. indica*, L., is employed for similar purposes with the European and American species, and the Arabians are said by Forskhal to use the leaves of *A. semper-virens* as a counter-poison. *A. fetida*, Kunth., of Mexico, or *Yerba del Indio*, is used as a local stimulant to foul ulcers. A number of species of *Aristolochia* are employed as a

remedy for snake-bites in various parts of the world, as *A. Serpentina*, L., in North America; *A. maxima*, L. (the rhizome of which is called *Guaco* or *Contra Capitano*), in South America; *A. anguicida*, L., in the Antilles; *A. brasiliensis*, Mart. et Zucc.; *A. cymbifera*, Mart. et Zucc.; *A. macroura*, Gom.; *A. trilobata*, L., etc. There is no sufficient reason for supposing that any one of them is effective.

Aristolochia Serpentina, L., *Sp. Pl.* (1753) 961; Willd., *Sp. Plant.* iv. 159; Bigelow, *Am. Med. Bot.*, iii. 82; Barton, *Med. Bot.*, ii. 41; B. & T. 246.—This species of *Aristolochia* is an herbaceous plant, with a short rhizome and numerous slender roots. Several stems often rise from the same rhizome. They are about eight or ten inches in height, slender, round, flexuose, jointed at irregular distances, and frequently reddish or purple at the base. The leaves are oblong-cordate, acuminate, entire, of a pale yellowish-green color, and supported on short petioles. The flowers proceed from the joints near the root, and stand singly on long, slender, round, jointed peduncles, which are sometimes furnished with one or two small scales, and bend downward so as nearly to bury the flower in the earth or decayed leaves. The tube of the calyx is curved like the letter S, enlarged at the base (ovary) and at its throat, the short limb being obtusely three-lobed. The anthers—six or twelve in number—are sessile, attached to the under part of the stigma, which is fleshy and from three to six-lobed. The fruit is an hexangular, six-celled capsule, containing several small flat seeds. The plant grows in rich shady woods throughout the Middle, Southern, and Western States, abounding in the valley of the Ohio and in the mountainous regions of our interior. It flowers in May and June. The root is collected in Western Pennsylvania, West Virginia, Ohio, Indiana, and Kentucky. As it reaches Philadelphia, it is usually in bales containing about one hundred pounds, and is often mixed with the leaves and stems of the plant, and with adhering dirt.¹

A. hastata, Nuttall, *Gen. of N. Am. Plants*, 200.—*A. sagittata*, Muhlenberg, *Catal.*—This is now considered to be nothing more than a variety of *A. Serpentina*, from which it differs in having hastate, acute, somewhat cordate leaves, and the lip of the corolla ovate. It flourishes on the banks of the Mississippi, in the Carolinas, and elsewhere. Its root scarcely differs from that of the official plant, and is frequently mixed with it, as is proved by the presence of the characteristic hastate leaves in the parcels brought into market.

A. reticulata, Nuttall, *Trans. Am. Phil. Soc.* (1837), 162; Bridges, *A. J. P.*, xvi. 118; Carson, *Illust. of Med. Bot.*, ii. 32, pl. 77.—This plant was probably first observed by Nuttall, as a specimen labelled "*A. reticulata*, Red River," in the handwriting of that botanist, is

¹ For an account of *A. hirsuta* see 18th ed., U. S. D., p. 1222.

¹ Brazilian *Aristolochia* as it comes into the European markets consists of pieces about 10 Cm. (4 inches) long, gray-brown, longitudinally wrinkled, the thickest roots being split; the transverse section shows a rather thick bark, and a ligneous cylinder, which is distinctly radiating, and contains wide dotted ducts and wood-fibres; the bark and medullary rays contain much starch, and, in numerous but slightly enlarged cells, a mixture of yellow resin and volatile oil. The taste and odor are warm and camphoraceous.

contained in the Herbarium of the Academy of Natural Sciences of Philadelphia. From a root similar to that of *A. Serpentina* numerous short, slender, round, flexuose, jointed stems arise, usually simple, but sometimes branched near the root. The older stems are slightly villous, the young densely pubescent. The leaves, which stand on very short villous petioles, are round or oblong-cordate, obtuse, reticulate, very prominently veined, and villous on both sides, especially upon the veins. From the lower joints of the stem four or five hairy, jointed peduncles proceed, which bear small leafy villous bracts at the joints, and several flowers on short pedicels. The flowers are small, purplish, and densely pubescent, especially at the base and on the ovary. The hexangular capsule is deeply sulcate. This species grows from Virginia to Louisiana, Texas, Arkansas, and Oklahoma.

Properties.—Virginia snakeroot is officially described as follows: "*Virginia Serpentina*.—Rhizome of oblique growth, about 2 Cm. long and about 2 Mm. in diameter; externally yellowish-brown, slightly annulate, the upper surface with numerous stem-scars or stem-bases, the lower surface bearing a dense tress of thin, branching roots from 4 to 7 Cm. long; fracture short, yellowish-brown; xylem in the roots 5-rayed; odor camphoraceous; taste bitter and aromatic." *U. S. Texas Serpentina* is officially characterized as follows: "The rhizome is about twice as large as that of *Virginia Serpentina*, of a grayish-brown color, and the roots are fewer, less interlacing, and thicker." *U. S.* It contains a larger percentage of volatile oil than does the other variety of the drug. The color of serpentaria, which in the recent root is yellowish, becomes brown by time; that of the powder is grayish. Examined microscopically, the rhizome is seen to have only a moderately thick bark, composed chiefly of small-celled liber tissue; the woody tissue is formed of reticulated or pitted vessels and long prosenchymatous cells; the medulla is situated to the upper side of the centre, and has its cells large and thin-walled. The root yields all its virtues to water and alcohol, producing with the former a yellowish-brown infusion, with the latter a bright greenish tincture, rendered turbid by the addition of water. Chevallier found in the root volatile oil, a yellow bitter principle, soluble in water and alcohol, resin, gum, starch, albumen, lignin, and various salts. Buchholz obtained from 1000 parts, 5 of a green fragrant volatile oil, 28.5 of a yellowish-green resin, 17 of extractive matter, 181 of gummy extract, 624 of lignin, and 144.5 of water. The active ingredients are probably the volatile oil and the yellow bitter principle of Chevallier, which that chemist considers analogous to the bitter principle of quassia; alkaline solution of cupric tartrate shows, moreover, the presence of a glucose sugar. The volatile oil passes over with water in distillation, rendering the liquid milky, and impregnating it with the odor

of the root. The volatile oil has been carefully investigated by J. C. Peacock (*A. J. P.*, 1891, 257). He found it to contain a terpene, $C_{10}H_{16}$, boiling at $157^{\circ} C.$, of sp. gr. 0.865 (probably pinene); a compound ester boiling at $211^{\circ} C.$, sp. gr. 0.9849, which on saponification yielded borneol, $C_{10}H_{16}O$, and a crystalline acid; a fraction boiling at from 239° to $240^{\circ} C.$, sp. gr. 0.9888, and of the composition $C_{18}H_{20}O$; and some green or bluish-green fluorescent oil in small quantity, which decomposes even when distilled under reduced pressure. The borneol ester constitutes about 60 per cent. of the oil. A principle called *aristolochine*, obtained from *A. Clematidis* and the roots of *A. rotunda* and *A. longa*, was investigated by Jul. Pohl (*A. E. P. P.*, xxix.) He obtained it as a yellow crystalline mass, soluble in chloroform, ether, acetone, acetic anhydride, and alcohol, insoluble in petroleum benzin, benzene, and carbon disulphide, almost insoluble in cold water, slightly soluble in hot water. An ultimate analysis gave for its composition $C_{32}H_{42}NO_{13}$. O. Hesse obtained from the root of *Aristolochia argentina* an alkaloid to which he gives the name *aristolochine*, but has furnished no formula; a principle, *aristolin*, $C_{15}H_{28}O_8$; *physosterin palmitate*, in white scales, fusing at $82^{\circ} C.$; and a mixture of acids to which he gives the names *aristic acid*, $C_{18}H_{31}NO_7$, *aristic acid*, $C_{17}H_{30}(CH_3)NO_7$, and *aristic acid*, $C_{15}H_{29}NO_7$.¹

The roots of *Spigelia marilandica* are sometimes found associated with serpentaria. They may be distinguished by the absence of the bitter taste, and, when the stem and foliage are attached, by the peculiar character of these parts. (See *Spigelia*.) We have seen the young roots of *Polygala Senega* mixed with serpentaria. Independently of their difference in odor and taste, they may be distinguished by being simple, and by a projecting line running from one end to the other of the root. Another adulteration was detected by P. S. Milliman of Chicago, who found in a parcel a large quantity of "golden seal" (*Hydrastis canadensis*). The rhizomes, with rootlets attached, were from a quarter of an inch to an inch in length, and about one-eighth of an inch in diameter (*A. J. P.*, 1874, p. 516), but at the present time (1906) on account of the high price of senega and hydrastis neither admixture is likely to occur again.

Uses.—Serpentaria is a feeble stimulant tonic. Too largely taken, it occasions nausea, griping pains in the bowels, sometimes vomit-

¹ The resinous *aristic acid* has been obtained from a number of species of the genus *Aristolochia*, notably by Walz from *A. Clematidis*, by Chevallier from *A. Serpentina*, by Dymock and Warden from *A. indica*, by Hesse from *A. argentina*, by Hooper from *A. bracteata*. Hooper has also obtained a closely allied, if not identical, resinous acid from the aristolochaceous plant *Bragantia Wallichii*, besides an alkaloid, which, under the name of *Alpam*, has long been used in Western India as an antidote to snake venom. The allied species, *Bragantia tomentosa* of Blume, is said to be employed in Java as an emmenagogue.

ing and dysenteric tenesmus. It has been recommended in *intermittent fevers*, and may be serviceable as an adjunct to quinine. It is sometimes given in *dyspepsia*. The dose of fluidextract is from twenty minims to half a fluidrachm (1.3 to 1.8 Cc.). According to Pohl, aristolochine in sufficient dose produces in the higher animals violent irritation of the gastro-intestinal tract and of the kidneys, with death in coma from respiratory paralysis.

Dose, fifteen to thirty grains (1 to 2 Gm.).

SERUM ANTIDIPHThERICUM. U. S.

ANTIDIPHThERIC SERUM, DIPHThERIA ANTITOXIN

(sérûm ân'tî-dîph-thér'î-cûm)

"A fluid separated from the coagulated blood of a horse *Equus caballus* Linné, immunized through the inoculation of diphtheric toxin. It should be kept in sealed glass containers, in a dark place, at temperatures between 4.5° and 15° C. (40° and 59° F.)." *U. S.* "The blood serum of horses which have been immunized against the diphtheria poison." *P. G.*

Serum Antidiphthericum, *P. G.*; Diphtherie-hell-serum, *G.*; Serum antidiphthérique, *Fr.*; Siero antidifterico, *It.*; Suero antidifterico, *Sp.*

The antitoxic properties of the blood serum of animals immunized by the inoculation of bacterial toxins was discovered in 1890 by Behring and Kitasato (*D. M. W.*, Nos. 49, 50, 1890). The great practical therapeutic value of diphtheria antitoxin was demonstrated independently by Behring and Roux and announced in papers read before the International Congress of Hygiene and Demography which met in Budapest in 1894.

Only the serum of the blood is used in medicine for prophylactic or curative purposes, although other body juices contain the active principle. The antitoxin has never been isolated in pure form. It is precipitated with the globulins and is believed to be allied to the enzymes. The antitoxic-globulin retains its properties more persistently than the allied globulins with which it is associated. That is, it is more resistant to deleterious influences, more stable and more soluble than the other globulins found in blood serum. As we lack definite knowledge of the true chemical nature of the active principle contained in antitoxic serums, the antitoxin is variously spoken of as antikörper (*G.*) or anti-bodies, free receptors (*Ehrlich*), cytases (*Metchnikoff*), etc. Of the several antitoxins known, diphtheria antitoxin is the only one recognized by the *U. S. Pharmacopœia*. Each antitoxin is specific; that is, neutralizes the poison of the particular infection which was inoculated into a susceptible animal to produce it. While diphtheria antitoxin is used for

other diseases, it is specific only in neutralizing the poisons produced by the diphtheria bacillus. Diphtheria antitoxin is sometimes normally present in small amounts in the blood serum of guinea-pigs, horses, man, and other animals.

Preparation.—Diphtheria antitoxin is made by injecting the diphtheria poison (toxine) into horses. The horses are injected either subcutaneously or intravenously; usually the former method is preferred. Horses are selected because, on account of their size, a large amount of blood may readily be obtained, and because the horse is exceedingly sensitive to the diphtheria poisons. Behring originally employed dogs and sheep with success; Aronson preferred the goat; Roux was the first to use the horse.

The antitoxin is produced by a vital reaction of the cells of the body caused by the stimulation of the toxine. Just which cells of the body take most active part in the production of the antitoxin is not exactly clear. Metchnikoff believes this power lies almost solely with the phagocytes, while Ehrlich believes that any of the body cells, but especially the connective tissue cells, play the most important rôle. The followers of Ehrlich and Metchnikoff have built up two divergent schools of thought to account for antitoxic immunity. It is interesting to note that both schools place the nutrition and metabolism of the cell at the groundwork of antitoxin production.

The *toxine* is made by growing a virulent culture of the diphtheria bacillus in an alkaline nutrient bouillon at 37° C. This culture, when five to seven days old, is filtered through unglazed porcelain or diatomaceous earth in order to remove the bacterial cells. The clear filtrate, containing the soluble poisons elaborated by the growth and multiplication of the bacilli, is the diphtheria toxine. On account of the time and expense required to prepare the poison by filtering out the bacterial cells a simpler and quicker method is often used in establishments where large quantities are used daily. This method consists in simply killing the bacteria in the culture with trichresol (0.4 per cent.) or chloroform, allowing the bacterial mass to settle to the bottom and using the clear supernatant fluid,—which may be filtered through sterilized paper. This method does not remove all the bacterial cells, and is therefore more apt to cause reactive inflammation or abscess at the site of inoculation.

The horse is inoculated with increasing amounts of the toxine. At first 0.1 Cc. is used. This amount usually causes a local and constitutional reaction, swelling and oedema at the site of inoculation, fever and derangement of appetite. These symptoms pass away in a few days, when a larger quantity of toxine is then inoculated, and this process continued, until, within a few months the horse is able to withstand the subcutaneous inoculation of 500 to 1000 Cc. of a strong toxine with perhaps less local and general disturbance than is caused by the first treatment with a fractional part of

a cubic centimeter. As the doses of toxine given to the horse increase, the amount of antitoxin in the blood gradually increases until, after three to six months of treatment, the horse's blood usually contains from 200 to 400 units of antitoxin to the cubic centimeter. The production of stronger antitoxic serums depends upon the horse and not upon the treatment. Some horses react actively and produce very high potency serums for long times; others cannot be induced to give a serum containing more than 150 to 200 units per cubic centimeter. After a variable period (from several months to years) the horse loses the power of reaction so that despite active treatment the immunizing power of the blood serum steadily diminishes. The horse is bled from the external jugular vein by means of a trocar and canula. The blood is drawn into long sterile cylindrical flasks or tubes and allowed to clot. The clear serum collects and in a few days is drawn off by a pipette. This clear albuminous fluid is the Serum Antidiphthericum of the Pharmacopœia.

Preservatives.—The antitoxin in the blood serum immediately neutralizes the toxine when the two are brought into contact, but the antitoxic serum does not prevent the growth of the bacteria themselves. Diphtheria bacilli grow and multiply well in diphtheria antitoxic serum. In other words, diphtheria antitoxin is a good culture medium for bacteria of all kinds. The greatest care must therefore be taken to prevent contamination. The serum may be kept sterile indefinitely only by means of the most exacting bacteriological precautions. It is sometimes marketed without the addition of an antiseptic substance, but this practice has been largely discontinued for the following reasons: (1) The difficult technique required to prevent accidental contamination during the process of preparation and bottling; (2) the danger of the introduction of serious contamination by unskilled persons who use the serum; (3) the addition of a small amount of certain preservatives is harmless. Roux used camphor for this purpose, Behring phenol (0.5 per cent.), Aronson tricresol (0.4 per cent.), McFarland formaldehyde (1 to 1000); Theobald Smith prefers chloroform, as it does not cause a precipitate. Almost all the serums made by the American manufacturers contain tricresol.

Properties.—Antidiphtheric Serum is officially described as "a yellowish or yellowish-brown, transparent or slightly turbid liquid, odorless or having a slight odor due to the presence of the antiseptic used as a preservative. Specific gravity: 1.025 to 1.040 at 25° C. (77° F.). Antidiphtheric Serum gradually loses its power, the loss in one year varying between 10 percent. and 30 percent. Each container should be furnished with a label or statement, giving the strength of the Antidiphtheric Serum, expressed in antitoxic units, the name and percentage of the antiseptic used for

the preservation of the liquid (if such be used), the date when the Antidiphtheric Serum was last tested, and the date beyond which it will not have the strength indicated on the label or statement. The standard of strength, expressed in units of antitoxic power, should be that approved or established by the United States Public Health and Marine Hospital Service." U. S.

Tests.—*The Immunity Unit.*—The strength of antidiphtheric serum is expressed in Immunity Units. The unit is a measure of strength, not of quantity. The official unit for this country is the standard serum prepared and dispensed by the Hygienic Laboratory of the U. S. Public Health and Marine-Hospital Service in accordance with the law of July 1, 1902. The American standard is based on Ehrlich's normal serum made at the K. Institut für Experimentelle Therapie, Frankfurt a. Main, Germany. It is difficult to define the immunity unit in a brief sentence. A proper understanding of it may only be had from a study of the theoretical considerations involved (see "*The immunity unit for standardizing diphtheria antitoxin.*" Bulletin No. 21, Hygienic Laboratory, U. S. Public Health and Marine-Hospital Service, Washington, 1905). The unit may be defined as the neutralizing power possessed by an arbitrary quantity of a diphtheria antitoxic serum kept under special conditions to prevent deterioration in an authorized laboratory. From a theoretical viewpoint the unit may be defined as that quantity of diphtheria antitoxic serum which will just neutralize 200 minimal lethal doses of a pure poison. By a "pure" poison is understood one containing only toxin, and no toxoid, toxin, or other substances capable of uniting with the antibodies. The test by which the strength of antitoxin contained in a unit is measured is a physiological one and depends upon the neutralization of the toxine by the antitoxin. This neutralization can only be determined by injecting the toxine and antitoxin mixtures into guinea pigs, which animals are highly susceptible to the diphtheria bacillus and its poisons.

The preparation and preservation of the standard serum is encompassed by many technical difficulties. A high grade serum is selected. This is given a preliminary test to determine its potency. The serum is now reduced to dryness by evaporation at 37° C. in vacuo. Special apparatus is used to accomplish this evaporation quickly and at the same time to prevent contamination. The dried serum must be kept guarded under special conditions to prevent deterioration. The oxygen of the air must be excluded in order to retard the process of oxidation, which rapidly alters the antibodies, especially under the influence of light. The standard serum is, therefore, always kept in absolute darkness in the Hygienic Laboratory of the U. S. Public Health and Marine-Hospital Service. The serum must be

perfectly dry. It is therefore kept under the influence of phosphoric anhydride, P_2O_5 , as shown in the accompanying illustration. Fur-

U-shaped tubes used for preserving the standard serum. Half size.

ther, the serum is kept in a specially built ice box maintained at the constant temperature of 5° C. by means of circulating brine. The dried official serum is preserved in a small glass apparatus consisting of two parts connected by means of a glass tube. The serum is placed in one portion of the apparatus and phosphoric anhydride, which is a very powerful dehydrating substance, in the other. The air is exhausted as much as possible by means of a high vacuum and the apparatus hermetically sealed. After a few days the acid will have taken up all the moisture from the serum, and the tube connecting the two parts may then be melted and sealed off, separating the acid from the serum. Several hundred such tubes are prepared, each one containing a weighed quantity of the powdered serum. From this arrangement it will be seen that the powdered serum is kept dry, free from contact with the oxygen of the air, guarded against the action of the light, and preserved at a constant low temperature. Once every two or three months, or whenever it is desired to test the serum, one of these bulbs is broken and 1 gramme of the serum carefully weighed and dissolved in a solution made by mixing physiological saline solution (0.85 per cent.) one part, and pure glycerin two parts.

TESTING THE STANDARD SERUM.—This glycerinated solution of blood serum is now accurately standardized in order to determine its precise antitoxic value in terms of Ehrlich's immunity unit. The number of immunity units contained in a given quantity of the serum is determined by the test ($L+$) dose of toxine (vide infra). That quantity of serum necessary to be added to the $L+$ dose of the toxine so that the mixture will kill the guinea pig on about the fourth day contains just one immunity unit. In the commercial testing of serums in order to have a coefficient of safety it would be safer to require the pig to live.

TESTING THE TOXINE.—The toxine is a complex substance composed, according to Ehrlich, of several poisons, viz., *toxin*, *tozoid*, *toxone* and

epitoxonoid. The diphtheria toxine is first investigated biologically by adding varying quantities of the poison to the immunity unit and inoculating the mixtures into a series of guinea pigs. In this way it is very evident, as Ehrlich has shown, that two limits, boundaries or zones are always shown, which are of the greatest importance in determining the nature and composition of the poison. Each of these limits is designated by the letter L , from *limes*, a boundary or zone. These limits are known respectively as L^0 ($0 = \text{nil}$) and $L+$ ($+= \text{death}$).

By L^0 is meant that quantity of poison which just neutralizes or saturates one immunity unit as shown at the necropsy done forty-eight hours after the subcutaneous injection of the mixture into the guinea pig. The reaction at the site of inoculation at this examination must be hardly noticeable. Theoretically the L^0 dose of toxine must unite with and neutralize just 200 "combining units" of antitoxin. The L^0 dose, therefore, contains just 200 minimal lethal doses of a theoretically pure poison.

By $L+$ is meant the smallest quantity of toxine which will neutralize one immunity unit, plus a quantity necessary to kill the animal on the fourth day. As defined by Ehrlich, the $L+$ dose is that quantity of poison which, despite the antibodies contained in one immunity unit of serum, contains a sufficient excess of poison to cause the death of the guinea pig within the course of four days.

In studying the constitution of the diphtheria poison it is also necessary to determine its absolute toxicity with the greatest possible precision. The absolute toxicity of the diphtheria poison is spoken of as the minimal lethal dose (MLD), sometimes as the minimal fatal dose (MFD), and occasionally as the simple lethal dose. The determination of the minimal lethal dose is often an exceedingly tedious problem. This is due in part to the fact that the determination of the exact limits is largely influenced by the individuality of the guinea pigs, so that it is necessary to repeat the work on a series of animals in order to reach an average.

The minimal lethal dose may be readily defined as that quantity of toxine which will surely kill every guinea pig weighing 250 grammes in the course of four days, or at the very latest, five days. As Ehrlich has pointed out, such a quantity may kill some of the animals sooner, that is, within thirty-six to forty-eight hours. A quantity of diphtheria poison that will kill every guinea pig, without exception, acutely within thirty-six to forty-eight hours contains more than the minimal lethal dose. The $L+$ dose is a much more definite and constant factor than the MLD. It does not show the irregularities or present the difficulties met with in determining the absolute toxicity of the poison. On account of the importance of the $L+$ and the L^0 doses

the following simplified tables taken from actual experiments are given to show just how these two factors are obtained:

through a Berkefeld filter. The concentrated antitoxin solution thus prepared contains probably from two to three times the proportion

Test to determine the L+ dose of a toxine.

	Result.
1 immunity unit + 0.19 Cc. toxine	Invariably causes late paralysis, never acute death.
1 immunity unit + 0.20 Cc. toxine	Sometimes causes late paralysis and sometimes acute death.
1 immunity unit + 0.21 Cc. toxine	Always causes acute death about the fourth day.
1 immunity unit + 0.22 Cc. toxine	Always causes acute death, usually on the second or third day.

The L+ dose of this toxine is, therefore, just 0.21 Cc.

Tests to determine the L⁰ dose of a toxine.

	Result at autopsy 48 hours after inoculation.
1 immunity unit + 0.14 Cc. toxine	No visible reaction.
1 immunity unit + 0.15 Cc. toxine	No visible reaction.
1 immunity unit + 0.16 Cc. toxine	Slightest possible congestion about carbon particles or no reaction.
1 immunity unit + 0.17 Cc. toxine	Apparent reaction at site of inoculation.
1 immunity unit + 0.18 Cc. toxine	Injection and cedema at site.
1 immunity unit + 0.19 Cc. toxine	Injection and cedema at site.

The L⁰ dose of this toxine, therefore, is 0.16 Cc.

CONCENTRATED SERUMS.—At one time it was the practice of some manufacturers to concentrate the unit strength of weak serums by evaporation in vacuo at a temperature of 40° C. or less. This produces a liquid of higher specific gravity, containing the original antitoxic strength, but in less liquid. This form of concentration has not met with favor and serves no useful purpose. As the concentrated blood serum is more difficult of absorption and possibly more irritating, the practice has been entirely abandoned. Another method of concentration now employed by the New York Board of Health (Gibson, R. B.: *Jour. of Biol. Chem.*, vol. i., Nos. 2, 3, Jan. 1906) is as follows: The serum is precipitated with an equal volume of saturated ammonium sulphate solution and the precipitate extracted with a solution of saturated commercial sodium chloride. The antitoxin globulin dissolves in the latter and the insoluble globulin is separated by filtration. The antitoxin is separated from the filtrate by the addition of a half volume of saturated ammonium sulphate solution; or, better still, by the addition of acetic acid in the usual way. The precipitate separated by filtration is pressed as dry as possible between absorbent paper and dialyzed a few hours in parchment paper. The resultant dialyzed solution is then neutralized and redialyzed for several days. A quarter of one per cent. of sodium chloride and some toluol are added and sterilization effected by double filtration

of protein present in normal serum. Large quantities of serum can be worked over at comparatively small expense by the method indicated. The product thus prepared is claimed to be as good as ordinary antitoxin serum. Tests made by the New York Board of Health show that the artificially concentrated antitoxin kept in small vials in an ice box, preserves its potency as well or even better than the ordinary antitoxin serum. Therapeutically the comparative results obtained are identical. Local irritation, rashes, etc., seem to be less frequent and severe when this concentrated or "refined" antitoxin is administered.

DRIED ANTITOXIC SERUM.—The dried antidiphtheric serum is official in the German pharmacopœia and is also prepared by the Pasteur Institute of Paris, France, for general sale. This dried product is little used in the United States on account of the difficulty found in bringing it into solution and the inconvenience of preparing a sterile solution. The dried serum retains its potency a much longer time than the liquid serum. The serum is dried in vacuo, either in shallow pans or by allowing warmed, dried and sterile air to bubble through the liquid. Precautions must be taken during the process to prevent bacterial contamination. The serum is simply reduced to dryness and the golden yellow flakes ground into a fine powder, in which state it is found upon the market in hermetically sealed vials. The dried serum contains no antiseptic or other added

substance. It appears as a yellowish-white powder, soluble in ten parts of water, giving a solution which in color and appearance resembles the corresponding antidiphtheric serum. The solution should be made with sterile water and in the original bottle, and should be freshly prepared each time. The solution should be clear, except for little albuminous particles. It is used for subcutaneous injection in exactly the same way as the liquid serum.

LEGAL REQUIREMENTS.—All diphtheria antitoxin sold in interstate commerce in this country must comply with the regulations made in accordance with the law approved July 1, 1902, entitled "An Act to regulate the sale of viruses, serums, toxins, and analogous products in the District of Columbia, to regulate interstate traffic in said articles, and for other purposes." It is illegal to sell, barter or exchange diphtheria antitoxin made in one State or Territory or the District of Columbia in another State or Territory or the District of Columbia unless the following salient points of the law have been complied with: 1. The product must be plainly marked with the proper name of the article contained therein; 2, the label on the package must plainly state the name of the manufacturer; 3, the package must be plainly labeled with the license number issued by the Secretary of the Treasury; 4, the date beyond which the contents cannot be expected, beyond reasonable doubt, to yield specific results must be given on the label or package. The execution of the law rests with the Surgeon-General of the U. S. Public Health and Marine-Hospital Service. Annual inspections of all licensed manufacturers are made by officers of the above named Service. From time to time products of each licensed manufacturer are bought on the open market and examined in the Hygienic Laboratory of the Public Health and Marine-Hospital Service at Washington for purity and potency.

Uses.—Diphtheria antitoxin is a true specific for diphtheria if it is given in sufficient quantity and sufficiently early in the disease. The very unfavorable results obtained in England in 1895 in the treatment of diphtheria with serum were due, according to the report of the Lancet Commission (*L. L.*, July 19, 1896), in a great majority of cases, to the use of serums too weak to produce therapeutic

results. Experimental researches, for example, the very careful work of Madsen in Copenhagen in 1896, showed that for therapeutic purposes weak serum is of very little value. Equally disappointing results will be obtained if the antitoxin is administered after the toxine has damaged the cells. The early use of the remedy is of the greatest importance. No time should be lost, not even the delay in waiting for bacteriological confirmation. As soon as diphtheria is suspected, from 2000 to 5000 units of antitoxin should at once be injected into the subcutaneous tissue. The reliable figures given in the table below, collected by Dieudonné (*Schutzimpfung und Serum Therapie*) shows conclusively the great practical value of diphtheria antitoxin and emphasizes the importance of administering the remedy early.

It will be seen from this table that every hour's delay lessens the chance of successful treatment. In cases treated within the first 24 hours of the onset of the disease the mortality is very small. "The bacteriological investigations of diphtheria in the United States" by William Welch (*Am. J. M. S.*, vol. 108, p. 427) show that 1115 cases of diphtheria treated in the first three days of the disease yielded a mortality of 8.5 per cent., whereas 546 cases in which the antitoxin was first injected after the third day of the disease a mortality of 27.8 per cent. resulted. Welch's statistics gathered from the hospitals of the world show conclusively that the antitoxin treatment produces "an apparent reduction of case mortality of 55.8 per cent." Numerous statistics from all parts of the world upon the effect of the antitoxin treatment of diphtheria are practically unanimous in showing the good results of this remedy. The great value of diphtheria antitoxin is perhaps most strikingly seen in the laryngeal cases.

The curative dose is usually 2000 to 5000 units, which should be repeated every four to eight hours until favorable results are manifest. As much as 67,000 units have been given to a patient with favorable results (St. Clair Street, *Med. Rec.*, Nov. 18, 1905). Fortunately the serum is usually harmless even when injected in large quantities. The remedy should always be given by the hypodermic method. Strict asepsis must be observed. The liquid may be injected under the skin of any part of the body where the subcutaneous tissue

is loose. The back, near the angle of the scapula, is a favorite site for inoculation; sometimes the flank, or abdominal walls are chosen. The exhibition of the remedy by the mouth or per rectum is uncertain, slow and unsatisfactory. The use of antitoxin should not exclude the ordinary local treatment, such as gargles, sprays, and applications to the throat.

Diphtheria antitoxin is just as valuable for prophylaxis as for curative purposes. The passive immunity produced by the inoculation of the antitoxin serum does not last very long. The transitory nature of the immunity afforded by prophylactic injections is probably dependent upon the fact that the antitoxin is slowly excreted by the kidneys. The usual prophylactic dose for a child is 500 units. If the exposure to the infection continues the dose should be repeated in three or four weeks. The antitoxin in the blood neutralizes the toxine elaborated by the bacilli growing on the mucous membrane of the throat, but has no deleterious effect upon the bacilli themselves. The micro-organisms in this situation may continue to grow and remain virulent for months. This is the explanation of occasional failures of the antitoxin to prevent a subsequent attack of the disease.

Though the serum is usually harmless, sometimes urticaria, localized erythema and joint pains follow its administration. These symptoms commonly pass away without untoward consequences. The serum appears not to irritate the kidneys, even when injected into the tissues in very large amounts. Occasionally sudden death immediately follows the injection of diphtheria antitoxin. The cause of this unfortunate result is explained as occurring in persons with the so-called *status lymphaticus*. Such persons stand shock badly and would succumb to other trivial surgical operations. See "A study of the cause of sudden death following the injection of horse serum," Rosenau and Anderson. (*Bull.* 29, Hyg. Lab., P. H. and M. H. S.)

Diphtheric antitoxin gradually loses its strength, especially when kept under unfavorable conditions of light, temperature, etc. The loss in one year is usually from 10 to 30 per cent.; however, a serum will retain considerable antitoxic potency after years. Except for its diminished potency an old serum is quite as good as one freshly prepared; so that in an emergency or in order to save time an old serum may be administered, provided it remains uncontaminated.¹

¹ OTHER FORMS OF ANTITOXINS.—*Tetanus Antitoxin. Antitetanic Serum.*—Tetanus heilserum, G.; Serum Antitetanico, Fr.; Siero Antitetanico, It.

Tetanus antitoxin was the first of the curative serums to be discovered by Behring and Kitasato, in 1890 (*D. M. W.*, No. 49, 1890), which work contained all the essentials of modern serum therapy.

The tetanus bacillus and the diphtheria bacillus are types of the pathogenic micro-organisms which produce strong and specific soluble poisons when grown in pure cultures *in vitro*. It is owing to this property that potent and useful antitoxins are readily obtainable against these two infections, by injecting the toxins into susceptible animals. The

PREPARED SUET [Serum, Pharm. 1890]

(sē'vūm præ-pa-rā'tūm)

"The internal fat of the abdomen of the sheep *Ovis aries* Linné, purified by melting and straining. Prepared Suet should be kept

toxine found in the filtered bouillon of a pure culture of the tetanus bacillus is the most virulent poison known. The purified and dried tetanus toxin prepared by Brieger and Cohn was fatal to a 15 gramme mouse, in a dose of 0.000,000,05 gramme.

There are two toxins produced by the tetanus bacillus in pure culture,—tetano-spasmin and tetanolysin. The former exerts its poisonous influence upon the ganglionic motor nerve cells and causes the well known muscular contractions which characterize the disease (lockjaw). The latter (tetanolysin) acts as a dissolving agent upon the red corpuscles of the blood and is of minor importance.

Few organisms are distributed more widely and generally about all inhabited localities than tetanus. It is found in the dejecta of a large number of mammalian animals in whose intestinal tracts it finds favorable conditions for growth and multiplication. The spores are exceedingly resistant and are blown about in the dust so that they contaminate many objects and surfaces. The tetanus bacillus is a strict anaërobie; that is, it cannot grow or multiply in the presence of oxygen. It is therefore easy to understand why punctured wounds, such as are made by dirty nails, splinters, toy pistols, etc., are especially prone to this infection.

Tetanus antitoxin is made in all respects similar to Serum Antidiphthericum (*q.v.*) by injecting increasing amounts of the specific poison subcutaneously into horses. The antitetanic serum has the same physical and chemical properties as diphtheria antitoxin. It is also tested in the same way, both as to purity and potency. At present there is no American unit for standardizing the potency of tetanus antitoxin, but one is now in process of preparation in the Hygienic Laboratory of the Public Health and Marine-Hospital Service.

It has been shown experimentally by Marie and Morax, and Ransom and Meyer that the poisons produced by the tetanus bacilli growing in a wound travel up the axis cylinder of the motor nerves until they reach the central motor ganglia.

After the symptoms have once appeared, indicating that the toxine has reached and injured the motor nerve cells, the antitoxin is of little avail. The principle use of tetanus antitoxin therefore is as a prophylactic. Ten Cc. of the antitoxic serum should be administered in all cases of wounds threatened with the complication of tetanus. This applies especially to punctured wounds with old dirty nails and other objects liable to contamination with street dirt, garden earth or manure. In addition to this the wound should be freely opened and cleaned surgically with appropriate antiseptics. The prophylactic use of tetanus antitoxin is equally valuable in wounds of horses and other susceptible animals as in man. The dried and powdered antitetanic serum is sometimes used to dust upon the wound in order to neutralize the poison *in situ*.

If the case is not seen sufficiently early to use the antitoxin as a prophylactic, 1 to 3 Cc. of the serum may be injected into the nerve trunk leading from the wound. In this way the serum will reach the affected nerve cells sooner and more surely than when injected subcutaneously or into a vein. When the symptoms are well advanced very large quantities of the remedy should be used subcutaneously or intravenously. Ten Cc. or more may be injected every four to six hours for several days or until a favorable effect is noted. In severe cases, in addition to applying the antitoxin locally to the wound and injecting some into the nerve trunk, it should also be administered intravenously, as well as subcutaneously.

Tetanus antitoxic serum has also been injected into the cerebrospinal space or directly into the brain matter by trephining. It has also been injected into the spinal cord; but experience seems to indicate that these methods have no advantages over those already stated.

Tubercle Antitoxin. Antitubercle Serum.—This serum is prepared by injecting tuberculin and other toxic products of the tubercle bacillus into horses, asses, goats, and other animals. Maragliano and Marmorek have prepared antitubercle serums by special methods. The serums thus obtained have

in well-closed vessels impervious to fat. It should not be used after it has become rancid." *U. S.* "The internal Fat of the abdomen of the sheep, *Ovis Aries*, *Linn.*, purified by melting and straining." *Br.*

Sesum, *U. S.* 1890; Sesum Ovillum; Mutton-Suet, Prepared Mutton Tallow; Suif de Mouton, *Fr. Cod.*; Graisse de Mouton, *Fr.*; Sesum ovile, *P. G.*; Hammeltalg, Talg, Schöpsentalg, Unschlitt, *G.*; Grasso di Moutone, Grasso duro, *It.*; Sebo de carnero, *Sp.*

Suet is the fat of the sheep, taken chiefly from about the kidneys. It is prepared by cutting the fat into pieces, melting it with a moderate heat, and straining it through linen or flannel. In order to avoid too great a heat, the crude suet is sometimes purified by boiling it in a little water. Mutton suet is of a finer consistence, and requires a higher temperature for its infusion, than any other animal fat. It is very white, sometimes brittle, inodorous, of a bland taste, insoluble in water, and nearly so in alcohol. Boiling alcohol, however, dissolves it, and deposits it upon cooling. It consists, according to Chevreul, of stearin, palmitin, and olein, containing approximately 70 per cent. of stearin and palmitin and 30 per

cent. of olein. These principles are described under the *Fixed Oils* (page 806). It is officially described as "a white, solid fat, nearly inodorous, and having a bland taste when fresh, but becoming rancid on prolonged exposure to the air. Insoluble in water or cold alcohol; soluble in 44 parts of boiling alcohol, in about 60 parts of ether, and slowly in 2 parts of petroleum benzin. From its solution in the latter, when kept in a stoppered flask, it slowly separates in a crystalline form on standing. An alcoholic solution of Prepared Suet is neutral or has only a slightly acid reaction to litmus paper moistened with alcohol. Prepared Suet melts between 45° and 50° C. (113° and 122° F.), and congeals between 37° and 40° C. (98.6° and 104° F.)." *U. S.* "White, smooth, almost odorless; melting point between 112° and 120° F. (44.4° and 48.9° C.); commences to re-solidify at about 100° F. (37.8° C.). Freely soluble in *petroleum spirit*, slowly soluble in *benzol*, insoluble in cold alcohol (90 per cent.), slightly soluble in *ether* or boiling alcohol (90 per cent.)." *Br.* E. Dieterich examined a large number of samples of mutton and beef suet, and found that they were without exception acid and that neutral suet does not exist. The melting point of mutton suet is between 48.5° and 50.5° C.; that of beef suet, between 47.5° and 48° C. The specific gravity of mutton suet lies between 0.937 and 0.952; that of beef suet, between 0.943 and 0.952. (*A. Pharm.*, 1887, 496.)

Streptococcus Antitoxin. *Antistreptococcus Serum.* *Streptococcus Hellsrum, G.*; *Serum Antistreptococcique, Fr.*; *Siero Antistreptococco, It.*

Antistreptococcus Serum is prepared by inoculating pure cultures of streptococci into horses. At first, killed cultures are used and afterwards the live and virulent organisms are injected either subcutaneously or intravenously. There are many different strains of streptococci, some of them exceedingly virulent; others appear to be nonpathogenic. Streptococci are the cause of erysipelas, puerperal fever, and are frequently found associated with or complicating scarlet fever, smallpox, phlegmonous inflammations, tuberculosis, sore throat, etc., etc.

The antistreptococcus serums found upon the market are sometimes prepared with particular cultures. More often the serum is polyvalent; that is, several virulent cultures from different sources are used in inoculating the animals. There is no satisfactory test for the potency of antistreptococcus serum. These serums really contain little if any antitoxic power. The tests for purity are similar to those used for other serums. The physical and chemical properties of antistreptococcus serum are similar to other serums.

Antistreptococcus serum is used in *erysipelas*, *puerperal fever*, *scarlet fever* and other diseases caused or complicated with the streptococcal infections. The results obtained are contradictory and not altogether satisfactory. The usual dose is 10 Cc. every six hours.

Yersin Serum. *Plague Antitoxin.* *Antipest Serum, G.*; *Serum Antipesteuse, Fr.*

The Yersin serum is prepared by the inoculation of horses with increasing doses of pure cultures of the plague bacillus. First, dead cultures, afterwards living organisms, are used. The injections are made either subcutaneously or intravenously. The blood serum of horses treated for a long period of time by this method contains antitoxic properties useful in plague as a prophylactic or curative agent.

Yersin has also prepared a serum against cholera by similar methods; but this has proven less valuable in actual practice. These serums must not be confused with the *Haffkine prophylactics* for plague and cholera, which consists of dead cultures and are used to produce an active immunity as contrasted with the passive immunity caused by antitoxic serum. The Haffkine prophylactics must not be used as curative remedies, as they contain the toxine. To administer them during the course of the disease would be adding fuel to the flames.

BLACK MUSTARD

(si-ná'pís ní'grá)

"The seed of *Brassica nigra* (Linné) Koch (Fam. *Cruciferae*)."
U. S. "The dried ripe seeds of *Brassica nigra*, Koch." Br.

Sinapis Nigrae Semina, Br.; Black Mustard Seeds; *Semina Brassicae*; Moutarde noire, Fr. *Cod.*; Moutarde, Fr.; Semen Sinapis, P. G.; Senfsamen, Schwarzer Senf, G.; Senape nera, It.; Mostaza (Semilla de), Sp.

Linnæus described two genera, *Brassica* and *Sinapis*, and subsequent botanists have greatly disagreed as to whether they should be considered identical or not. The British Pharmacopœia still follows Bentham and Hooker, but the revisers of the U. S. P. have adopted the opinion of Engler and Prantl and Britton and Brown, that the two genera are distinct. The genus *Sinapis* differs from *Brassica* in that the pods of the former are terminated by a long, flat, sword-like beak, whereas in *Brassica* the beak is cylindrical or conical.

Brassica nigra, Koch, in *Roehl. Deutschl. Fl.* (1833), 713.—*Sinapis nigra*, Linné, *Sp. Pl.* (1753) 668.—Common or black mustard is an annual plant, with a stem three or four feet in height, divided and subdivided into numerous spreading branches. The leaves are petiolate and variously shaped. Those near the root are large, rough, lyrate-pinnate, and unequally toothed, those higher on the stem are smooth, and less lobed, and the uppermost are entire, narrow, smooth, and dependent. The flowers are small, yellow, and stand closely together upon peduncles at the upper part of the branches. The pods are smooth, erect, nearly parallel with the branches, quadrangular, and furnished with a slender beak; seeds numerous, dark brown.

Sinapis alba, Linné, *Sp. Pl.* (1753) 668; *Brassica alba*, Boiss., *Voy. Espag.* (1839-45) 39.—The white mustard is also annual. It is rather smaller than the preceding species. The lower leaves are deeply pinnatifid, the upper sublyrate, and all irregularly toothed, rugged, with stiff hairs on both sides, and pale green. The flowers are in racemes, with yellow petals, and linear, green calycine leaflets. The pods are spreading, bristly, rugged, roundish, swelling in the position of the seeds, ribbed, and provided with a very long ensiform beak.

Both plants are natives of Europe and cultivated in our gardens, and *B. nigra* has become naturalized in some parts of this country. Their flowers appear in June. The seeds are kept in the pharmacies, both whole and in the state of very fine powder as prepared by the manufacturers for the table.¹ The latter

is sometimes mixed with spice and ground into a smooth paste with water in a mill resembling a paint mill, and then is known as *French mustard*.

The *Brassica juncea*, Coss. (*Sinapis juncea*, L.), is extensively grown in India, and its seeds are largely exported to Europe. The same plant is also cultivated in Southern Russia. The seeds afford a very fine yellow mustard flour, and, according to Paul Birkenwald, yield 1.67 parts per hundred of volatile oil, against 1.89 parts per hundred by the true black mustard seed. (*S. W. P.*, 1888.)

Black mustard seeds are officially described as "subglobular, about 1.2 Mm. in diameter; testa deep red-brown, sometimes with a grayish tinge, minutely pitted; embryo greenish-yellow, oily, with a curved hypocotyl and two conduplicate cotyledons; odor while dry, slight, on moistening, powerfully irritating; taste strongly pungent and acrid. The powder contains few or no starch grains." U. S. *White mustard seeds* are "subglobular, 1 to 2 Mm. in diameter; testa yellowish, minutely pitted; embryo yellowish, oily, with a curved hypocotyl and two conduplicate cotyledons; inodorous; taste mildly pungent and acrid. The powder contains few or no starch grains." U. S. Both afford a yellow powder, which has a somewhat unctuous appearance, and cakes when compressed. This is commonly called *flour of mustard*, or simply *mustard*, and is prepared by crushing and pounding the seeds and then sifting them, the purest flour being obtained by a second sifting. Both the black and the white seeds are used in its preparation. It is often adulterated with wheat flour colored by turmeric, to which red pepper is added to render the mixture sufficiently hot. Pure mustard powder contains very few starch granules, but is frequently adulterated with farinaceous powders; the U. S. P. requires that White or Black Mustard should conform to the following test. "If 1 Gm. of powdered White (or Black) Mustard be exhausted by slow percolation with alcohol, and the marc mixed with 200 Cc. of water and heated to boiling, and if, after cooling, sufficient cold water be added to make the mixture measure 1000 Cc., the addition of 4 Cc. of tenth-normal iodine V.S. should not produce a dark blue color (limit of starch)." U. S. The epidermis of white mustard seeds contains a mucilaginous substance which is extracted by boiling water. When bruised or powdered, both kinds impart their active properties wholly to water, but in a very slight degree to alcohol. They yield upon pressure a fixed oil, called *oil of mustard*, of a greenish-yellow color, little odor, and a mild not unpleasant taste; and the portion which remains is even more pungent than the unpressed seeds. The

¹The seeds of *Brassica ibertifolia*, according to O. Harz, are sometimes sold as true white mustard seed. He examined some obtained from Bavaria, which had been returned by customers to the dealers on account of their bitter and disagreeable taste. He furnishes characteristic microscopical tests for

distinguishing the false from the true mustard seed. His statement, however, that powdered white mustard seed when mixed with water is odorless, and that the false gives off a strong odor of essential oil of mustard, would seem to be a good reason, if correct, for preferring the false seed. (*P. J.*, 1887, 478.)

fixed oil of mustard consists of the glycerin compounds of stearic, oleic, and *erucic* or *brassic* acid, $C_{22}H_{42}O_2$, a homologue of oleic acid. Small quantities of *behenic* acid, $C_{22}H_{44}O_2$, also occur in oil of black mustard. This fixed oil is a yellow non-drying oil of from 0.915 to 0.920 sp. gr. at $15^{\circ} C.$, solidifying at from -12° to -16° .¹ It has been long known that black mustard seeds yield by distillation with water a very pungent volatile oil, containing sulphur. Guibourt conjectured, and Robiquet and Boutron proved, that this oil does not pre-exist in the seeds, but is produced by the action of water. Hence the absence or very slight degree of odor in the seeds when bruised in a dry state, and their pungency when water is added. It seemed reasonable to suppose that the reaction in this case was similar to that exercised by water upon bitter almonds (see *Amgydala Amara*), and this has been proved to be the fact by the experiments of Simon, Bussy, Boutron, and Frémy. The composition and peculiar decompositions of the volatile oil of black mustard have already been described. (See *Oleum Sinapis Volatile*.)

A principle was extracted by Will from white mustard seed, with the aid of alcohol. It has been named *sinalbin*, and has the formula $C_{30}H_{48}N_2S_2O_{16}$. It is decomposed, after the analogy of sinigrin (potassium myronate), into acrinyl sulphocyanate, C_8H_7NSO , sinapine bisulphate, $C_{16}H_{26}NSO_6$, and sugar, $C_6H_{12}O_6$, an albuminoid substance being formed at the same time. "The acrinyl sulphocyanate (C_8H_7NSO) is a very active principle, oily, insoluble in water, not volatile. It may be obtained by causing ether to act on the product of the decomposition of sinalbin. Treated by an alkali and then neutralized by an acid, it colors ferric chloride red." (*J. P. C.*, Avril, 1872, 327.)

The analyses of mustard seeds and mustard flour given in table, page 1126, are by Piesse and Stansell (*Analyst*, 1880, p. 161).

¹ *Mustard Seed Oil*.—F. W. Widmayer communicates some practical information concerning the character, yield, etc., of the fixed oil of mustard seed, which is largely obtained as a by-product in the manufacture of powdered mustard from both black and white mustard seed. The oil from yellow seed is of a greenish yellow color, that of the brown seed a much darker shade. Both have but little odor and a mild, not unpleasant taste. It is a semi-drying oil. The analytical data showing maximum and minimum results by M. L. Tolman and L. S. Munson on five samples are as follows: Specific gravity at $15.5^{\circ} C.$ 0.9147 to 0.9193; Butyrefractometer reading (15.5°) 74.5 to 78.5; Index of refraction at 15.5° 1.4750 to 1.4762; Maumené number 61.4 to 70.4; Specific temperature reaction 130.9 to 190.3; Hübl number 98.4 to 113.0; Saponification value 173 to 182.8; Melting point of fatty acids 20.8° to $21.5^{\circ} C.$; Free fatty acids as oleic .13 to 1.13 per cent.; Solidification from -3° to -18° . One remarkable feature of this oil is its penetrating or diffusing power. Barrels that will hold olive, cotton seed, or petroleum oils or even new oil or alcohol barrels invariably leak on being filled with it, and it is said by one who has had extensive experience in the mustard business that it has been known to come through a tank which had stood a pressure of 80 pounds of steam. (*D. C.*, 1904, 8.)

J. U. Lloyd has proposed standards for black and white mustard seed, mainly directed towards limiting the proportion of starch; the latter is not a constituent of ripe mustard seed, but commercial mustard nearly always contains starch, due to starch-bearing seeds accidentally present in the mustard seed, or to fraudulent admixture. (*A. J. P.*, 1898, 433.) Dieterich (*Ph. Ztg.*, Oct. 3, 1900, 767) proposed an assay for mustard seed, mustard oil and mustard paper.

Uses.—Mustard seeds swallowed whole operate as a laxative, and have acquired some reputation as a remedy in *dyspepsia*, and in other affections attended with torpid bowels and deficient excitement. The white seeds are preferred, and are taken in the dose of a tablespoonful (15.5 Gm.) once or twice a day, mixed with molasses, or previously softened and rendered mucilaginous by immersion in hot water. They probably act in some measure by mechanically stimulating the bowels. The powder, commonly called simply mustard, in the quantity of from one to two teaspoonfuls (3.9 to 7.7 Gm.), is an efficient and prompt stimulant emetic, especially valuable in *narcotic poisoning*. As a condiment mustard acts as a stimulant to the gastric mucous membrane, and by virtue of this stimulant action it will sometimes relieve obstinate *hiccough*. But mustard is most valuable as a rubefacient. Mixed with water in the form of a cataplasm, and applied to the skin, it very soon produces redness with burning pain, which in less than an hour usually becomes insupportable. When a speedy impression is not desired, especially when the sinapism is applied to the extremities, the powder should be diluted with an equal portion of rye meal or wheat flour. Care should be taken not to allow the application to continue too long, as vesication with obstinate ulceration, and even sphacelus, may result. This caution is particularly necessary when the patient is insensible and the degree of pain can afford no criterion of the sufficiency of the action. The volatile oil is powerfully rubefacient, and capable of producing speedy vesication, but certainly is less controllable than is the mustard poultice. For external application as a rubefacient, 30 drops of the oil may be dissolved in a fluidounce of alcohol, or 6 or 8 drops in a fluidrachm of almond or olive oil. (See *Limentum Sinapis Compositum*, U. S. 1890.) To form a *sinapism* it has been recommended to mix 20 drops of the volatile oil with a gelatinous mass made by heating together 3.5 drachms of glycerin and 5 drachms of starch. It has been given internally in *colic*, two drops being incorporated with a six-ounce mixture, and half a fluidounce (15 Ce.) given for a dose. In overdoses it is highly poisonous, producing gastro-enteric inflammation, and probably perverting the vital processes by pervading the whole system. Its odor is perceptible in the blood, and is said to impart the smell of horseradish to the urine. A *spirit of mustard* may

be prepared by macerating, for two hours, 250 parts of powdered black mustard with 500 parts of cold water, then adding 120 parts of alcohol of 86 per cent., and distilling over 120 parts of spirit.¹

Dose, one to two drachms (3.9 to 7.7 Gm.).

SODII ACETAS. U. S.

SODIUM ACETATE

(sō'di-i a-cē'tās)

"It should contain in an uneffloresced condition not less than 99.5 percent. of pure Sodium Acetate [$\text{CH}_3\text{COONa} + 3\text{H}_2\text{O}$], and should be kept in well-stoppered bottles." *U. S.*

Acetate of Soda; Acetas Sodicus (Natrius). Terra Follata Tartari Crystallisata, Terra Follata Tartari; Acétate de Soude Cristallisé, *Fr. Cod.*; Natrium Aceticum, *P. G.*; Natriumacetat, *Essigsaures Natron, G.*; Acetato di Sodio, *It.*

Sodium acetate may be easily prepared by adding crystals of sodium carbonate to acetic acid until it is neutralized, filtering, concentrating the solution, and crystallizing. It is prepared in the large way in the manufacture of crude pyroligneous acid, for the purpose of being decomposed, so as to yield the official acetic acid, by the action of sulphuric acid. The steps of the process by which it is made from the crude acid have been given under *Acidum Aceticum*.

Properties.—It is officially described as in "colorless, transparent, monoclinic prisms, or a granular, crystalline powder; odorless, and having a cooling, saline taste. Efflorescent in warm, dry air. Soluble in about 1 part of water, and in 23 parts of alcohol at 25° C. (77° F.); and in all proportions of boiling water and of boiling alcohol. When heated to 60° C. (140° F.), the salt begins to liquefy. At 123° C. (253.4° F.) it becomes dry and anhydrous; at 315° C. (599° F.) it is decomposed, with evolution of inflammable, empyreumatic vapors, leaving a black residue of sodium carbonate and carbon, which imparts to a non-luminous flame an intense yellow color, gives an alkaline reaction with litmus paper, and effervesces with acids. An aqueous solution of

the salt (1 in 20) should be alkaline to red litmus paper, but should not affect phenolphthalein. If a few particles of the salt be added to a mixture of 1 Cc. of sulphuric acid and 1 Cc. of alcohol, and heated to boiling, acetic ether will be formed, recognizable by its odor. On the addition of a few drops of ferric chloride T.S., the aqueous solution (1 in 20) assumes a deep red color, and, when boiled, yields a brown, flocculent precipitate of basic ferric acetate. A saturated aqueous solution should not be rendered turbid by the addition of sodium bitartrate T.S. (limit of *potassium*). Five Cc. of the aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzeit's Test for *arsenic* (see PART III, Test No. 17). The aqueous solution of the salt (1 in 20), slightly acidulated with acetic acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If 1 Gm. of Sodium Acetate be thoroughly carbonized at a temperature not exceeding red heat, and the residue extracted with boiling distilled water until the washings cease to react with methyl-orange T.S., the mixed filtrate and washings should require for complete neutralization not less than 14.7 (14.74) Cc. of half-normal sulphuric acid V.S., methyl-orange T.S. being used as indicator." *U. S.* Sodium acetate, when crystallized, consists of one acetic acid molecule, one atom of sodium and 3 molecules of water.

Uses.—Sodium acetate is diuretic, but is very rarely used as a medicine. It is employed principally to yield acetic acid by the action of sulphuric acid. In prescribing this salt, the fact, first noticed by Violette, should not be forgotten, that the mixture of equal parts of it and potassium nitrate, if heated, explodes with great violence. (*N. R.*, April, 1873.)

Dose, twenty grains to two drachms (1.3 to 7.7 Gm.).

Di-sodium-ortho-arsenate [$\text{AsO}(\text{OH})(\text{ONa})_2 + 7\text{H}_2\text{O}$], and should be kept in well-stoppered bottles." *U. S.* "The anhydrous salt, di-sodium hydrogen arsenate, Na_2HAsO_4 , obtained by exposing to a temperature of 300°F . (148.9°C .) crystallized sodium arsenate, which may be prepared by treating with water the product of the fusion of arsenious anhydride with sodium nitrate and sodium carbonate." *Br.* (See page 1128.)

Natrum Arsenicum, Arsenias Natricus (*Sodicens*); Sodium Arseniate; Arseniate of Soda; Arséniate de Soude, *Fr. Cod.*; Natriumarsenat, Arsensaures Natron, *G.*; Arseniato bisodico, *It.*; Arseniato sodico, *Sp.*

In the *U. S. P.* the crystallized and anhydrous salts are official, while the anhydrous salt is the only one recognized in the *Br.* authority.

The process for this salt was first made official by the *Br. Pharmacopœia* of 1864, and by the *U. S. Pharmacopœia* of 1870.¹ In the process, the arsenious acid (arsenic trioxide) is converted into arsenic acid at the expense of the nitric acid of the sodium nitrate, and then combines with the sodium of both salts, carbon dioxide and nitrous fumes being given off. The reaction seems to be as follows:

According to Higgins, the gases emitted in this process contain more or less arsenic,—an inconvenience which may be avoided by first dissolving the arsenious acid in a solution of sodium hydroxide, and then adding the nitrate. The calcination should be performed in a reverberatory furnace. The gases which escape up the chimney are now free from arsenic, and consist only of ammonia and nitrous vapors. (*J. P. C.*, 4e sér., ii. 177.)

Properties.—Sodium arsenate is in "colorless, transparent, monoclinic prisms, odorless, and having a mild, alkaline taste; caution should be used in tasting this salt, as it is very poisonous. Efflorescent in dry air, and somewhat deliquescent in moist air. Soluble in 1.2 parts of water at 25°C . (77°F .), and very soluble in boiling water; very sparingly soluble in cold, but nearly insoluble in boiling alcohol. When gently heated, the salt loses 5 molecules of water (28.8 percent.), and is converted into a white powder. At 148°C . (298.4°F .) it loses all of its water of crystallization, at a higher temperature the salt fuses, and at a red heat it is converted into pyroarsenate. Sodium Arsenate should respond to the tests of identity and

purity prescribed under *Sodii Arsenas Exsiccatus*." *U. S.* "A white powder, soluble in 6 parts of water, and yielding an alkaline solution. It is only slightly soluble in cold or boiling alcohol (90 per cent.). It affords the reactions characteristic of sodium and of arsenates. A solution of 1 gramme of Sodium Arsenate with 1 of *glacial acetic acid*, in 50 cubic centimetres of water, should require 2.03 grammes of *lead acetate* for complete precipitation. It should yield no characteristic reaction with the tests for lead, copper, iron, aluminium, calcium, magnesium, potassium, ammonium, carbonates, chlorides, nitrates, or sulphates. It should not lose weight on being heated to 300°F . (148.9°C .) (absence of hydrous sodium arsenate)." *Br.*

Anhydrous sodium arsenate has the composition Na_2HAsO_4 ; in crystals it sometimes contains 12 molecules of water, equal to 53.73 per cent. of its weight. According to the official formula, this salt crystallizes with 7 molecules of water, or 40.39 per cent. "The latter salt loses 40.38 per cent. of its weight when dried at 300°F . (148.9°C .), becoming anhydrous. An aqueous solution of 12.4 grains of anhydrous arseniate of sodium, acidulated with acetic acid, requires not less than 34 grains of acetate of lead for complete precipitation." *Br.* 1885. If the temperature of a solution of the salt be kept at 30°C . (86°F .), crystals will be deposited which contain 4 molecules of water. J. Lefort examined 10 different samples of the salt, obtained from as many different sources, and found their water of crystallization to vary from 44.05 to 57.45 per cent. (*J. P. C.*, 1880, 487.)

Uses.—In medicinal properties sodium arsenate corresponds with the other compounds of arsenic (see *Arseni Trioxidum*), and may be similarly employed. The dose of the crystallized salt is stated at from one-twelfth to one-third of a grain (0.005 to 0.021 Gm.), that of the anhydrous salt from one-fortieth to one-tenth of a grain (0.0016 to 0.006 Gm.); but it is generally prescribed in the form of solution. (See *Liquor Sodii Arsenatis*.) Arsenic has been used to a considerable extent hypodermically in the treatment of *chorea* and other nervous diseases. According to the clinical studies of H. N. Moyer, sodium arsenate is preferable to Fowler's solution for this purpose, as being more uniform in composition and less irritating. Sodium arsenate is used in the form of hypodermic tablets. Moyer gives from one-twentieth to one-tenth of a grain in from ten to fifteen minims of distilled water.

Pearson's arsenical solution is an aqueous solution of sodium arsenate, and much weaker than the official solution. It is made by dissolving 1 Gm. (15 grains) of sodium arsenate (crystallized) in 600 Cc. (20 fl. oz., 138 minims) of distilled water. This preparation is considerably used on the continent of Europe in the form of bath, for which it is preferred to arsenic trioxide or the arsenites. The arsenical

¹ "Take of Arsenious Acid, in fine powder, two troyounces; Nitrate of Sodium, in fine powder, eight hundred and sixteen grains; Dried Carbonate of Sodium, in fine powder, five hundred and twenty-eight grains; Distilled Water, boiling hot, half a pint. Having mixed the powders thoroughly, put the mixture into a large clay crucible, and cover with the lid. Expose it to a full red heat until effervescence has ceased, and complete fusion has taken place. Pour the fused salt on a porcelain slab, and as soon as it has solidified, and while it is still warm, put it into the hot water, and stir until it is dissolved. Filter the solution, and set it aside to crystallize. Drain the crystals, and, having dried them rapidly on filtering paper, keep them in a well-stoppered bottle." *U. S.* 1870.

bath has been especially commended by Guéneau de Mussy in *nodose rheumatism*, or *rheumatic gout*; dose for a bath, from half a drachm to three drachms (2.0 to 11.6 Gm.).

Dose, of crystallized sodium arsenate, one-tenth of a grain (0.006 Gm.); of the British dried salt, one-fortieth to one-tenth of a grain (0.0016 to 0.006 Gm.).

Off. Prep.—Ferri Arsenas, *Br.*; Liquor Sodii Arsenatis, *U. S.*, *Br.* (from dried salt); Sodii Arsenas Exsiccatus, *U. S.*

SODII ARSENAS EXSICCATUS.

U. S., *Br.*

EXSICCATED SODIUM ARSENATE

(sō'dī-i ār'se-nās ɛx-sic-cā-tūs)

$\text{Na}_2\text{HASO}_4 = 184.68$

"It should contain not less than 98 percent. of pure anhydrous Di-sodium-ortho-arsenate [$\text{AsO}(\text{OH})(\text{ONa})_2$]." *U. S.* (See page 1127.)

Sodii Arsenas, Br.; Natrium Arsenicum Exsiccatum; Dried (anhydrous) Arsenate of Soda; Arséniate de Soude desséché, *Fr.*; Getrocknetes Natriumarsenate, *G.*

"Sodium Arsenate Crystals, a sufficient quantity. Break the crystals into small fragments, and allow them to effloresce at a temperature between 40° and 50° C. (104° and 122° F.) until they are completely disintegrated; then gradually increase the temperature to 150° C. (302° F.), and continue the drying until the product ceases to lose weight. Reduce it to a fine powder, and transfer it to dry, well-stoppered bottles." *U. S.* This salt corresponds with the sodium arsenate of the British Pharmacopœia. As sodium arsenate and exsiccated sodium arsenate differ greatly in dose, they should each have a distinctive title as in the *U. S. P.* (8th Rev.). For properties see also *Sodii Arsenas*, page 1127.

Properties.—It is officially described as "an amorphous, white powder; odorless, and having a mildly alkaline taste; it should be tasted with great caution, as the salt is very poisonous. Permanent in dry air. Soluble in 3 parts of water at 25° C. (77° F.), and very soluble in boiling water; very sparingly soluble in cold, but nearly insoluble in boiling alcohol. When heated to 150° C. (302° F.), the salt should not lose weight; at red heat it is converted into pyroarsenate. It imparts an intense yellow color to a non-luminous flame. The aqueous solution of the salt (1 in 20) yields a white precipitate with barium chloride T.S., or with calcium chloride T.S., and a dark red precipitate with silver nitrate T.S., all of which precipitates are soluble in nitric acid. If 0.5 Cc. of an aqueous solution (1 in 20) be mixed with 2 Cc. of hydrochloric acid, and a drop of this mixture be placed upon a bright piece of copper-foil, then, upon applying a gentle heat, a dark steel-gray film will be deposited upon the copper. If to 2 Cc. of an aqueous solution (1 in 20), 5 Cc. of tenth-

normal silver nitrate V.S. be added, and the precipitate redissolved by a slight excess of ammonia water, no black precipitate of reduced silver should appear on boiling (absence of *arsenite*). If to 5 Cc. of an aqueous solution (1 in 20), 1 Cc. of ammonium sulphide T.S. be added, no dark coloration should appear (absence of *lead, copper, iron*, etc.)." *U. S.*

Uses.—Dried or exsiccated sodium arsenate is useful when it is desired to exhibit the salt in pill form, but differs in no way in its physiological action from sodium arsenate.

Dose, one-twentieth of a grain (0.003 Gm.).

SODII BENZOAS. *U. S.*, *Br.*

SODIUM BENZOATE

(sō'dī-i bēn'zō-ās)

$\text{NaC}_7\text{H}_5\text{O}_2 = 143.01$

"It should contain not less than 99 percent. of pure Sodium Benzoate [$\text{C}_6\text{H}_5\text{COONa}$], and should be kept in well-stoppered bottles." *U. S.* "Sodium benzoate, $\text{C}_6\text{H}_5\text{COONa}$, may be obtained by neutralizing benzoic acid with sodium carbonate." *Br.*

Sodæ Benzoas; Benzoate of Soda; Benzoate de Soude, *Fr. Cod.*; Natrium Benzolium, Natriumbenzoat, Benzosaures Natron, *G.*; Benzoato di sodio, *It.*; Benzoato sodico, *Sp.*

Sodium benzoate is easily made by adding benzoic acid to a concentrated hot solution of sodium carbonate or bicarbonate until effervescence ceases, and allowing the solution to cool and crystallize. R. Rother, in order to avoid annoyances in the effervescence, mixes four ounces of benzoic acid and two and three-fourths ounces of sodium bicarbonate in an evaporating dish with from two to four fluid-ounces of alcohol; when a uniform mixture is produced, from three to six fluidounces of water are added, heat applied gently, and the powder granulated.

Properties.—It is officially described as "a white, amorphous, granular or crystalline powder; odorless, and having a sweetish astringent taste. Permanent in the air. Soluble in 1.6 parts of water, and in 43 parts of alcohol at 25° C. (77° F.); in 1.3 parts of boiling water, and in 12 parts of boiling alcohol. When heated, the salt melts, emits vapors having the odor of benzoic acid, then chars, and finally leaves a residue of sodium carbonate and carbon. To a non-luminous flame it imparts an intense yellow color. Its aqueous solution is neutral or slightly alkaline to litmus paper. If a few drops of ferric chloride T.S. be added to an aqueous solution of the salt, a salmon-colored precipitate will be deposited. If 5 Cc. of diluted sulphuric acid be added to a solution of 1 Gm. of the salt in 10 Cc. of water, a white precipitate of benzoic acid will be produced, which, after being thoroughly washed, should conform to the tests of purity given

under *Acidum Benzoicum*. If an aqueous solution of the salt (1 in 20) be acidulated with hydrochloric acid and filtered, the filtrate should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If 1 Gm. of dry Sodium Benzoate be thoroughly ignited at red heat, and the residue extracted with boiling distilled water, until the washings cease to react with methyl-orange T.S., the mixed filtrate and washings should require for complete neutralization not less than 13.85 Cc. of half-normal hydrochloric acid V.S., methyl-orange T.S. being used as indicator." *U. S.* "Soluble in less than 2 parts of cold water, in 24 parts of cold alcohol (90 per cent.), and in 12 of boiling alcohol (90 per cent.). An aqueous solution has a faintly alkaline reaction, and gives a yellowish or flesh-colored precipitate when mixed with *test-solution of ferric chloride*. A strong aqueous solution, to which a little *diluted hydrochloric acid* is added, affords a crystalline precipitate of benzoic acid. Each gramme of the salt, when heated, melts, emitting an odor of benzoïn, then chars, and finally leaves a residue which affords the reactions characteristic of sodium, and, when dissolved in water, requires for neutralization from 6.8 to 6.9 cubic centimetres of the *volumetric solution of sulphuric acid*. It should yield no characteristic reaction with the tests for lead, copper, iron, calcium, magnesium, potassium, ammonium, or carbonates, and only the slightest reactions with the tests for chlorides or sulphates." *Br.*

Uses.—This salt was suggested as long ago as 1857 by Socquet and Bonjean, as a remedy in *gout* and *rheumatism*, and is certainly valuable in *lithæmia* and *lithæmic gravel* for the purpose of aiding in the elimination of uric acid. It has also been highly commended in *puerperal fever*, and in *tuberculosis*.¹ (*B. M. J.*, ii. 1879, 493, 982.)

Dose, from twenty to thirty grains (1.3 to 2.0 Gm.).

SODII BICARBONAS. U. S., Br.

'SODIUM BICARBONATE

(sô'di-I bî-câr'bô-nās)

$\text{NaHCO}_3 = 83.43$

"It should contain not less than 99 percent. of pure Sodium Bicarbonate [$\text{CO}(\text{OH})(\text{O Na})$], and should be kept in well-closed vessels, in a cool place." *U. S.* "Sodium Bicarbonate, NaHCO_3 , may be obtained by exposing crys-

tals of sodium carbonate to carbonic anhydride, or by the interaction of sodium chloride and ammonium bicarbonate." *Br.*

Natrium Carbonicum Acidulum; Bicarbonas Sodicus; Bicarbonate of Soda, Soda Saleratus, Acid Sodium Carbonate; Carbonate (Bi) de Soude, *Fr. Cod.*; Sel de Vichy, *Fr.*; Natrium Bicarbonicum, *P. G.*; Natriumbicarbonat, *Doppelkohlen-saures Natron, G.*; Bicarbonato di sodio, *It.*; Bicarbonato sodico, *Sp.*

Two kinds of sodium bicarbonate were formerly official,—one, which is known by the title of this article, and which, to comply with the tests, must not have more than one per cent. of impurity, and the other, "commercial bicarbonate," which must contain at least 95 per cent. of pure bicarbonate. Formerly to obtain a salt which would comply with the official test it was necessary to purify the commercial salt, and the process of the *U. S. Pharm.* 1870 will be found as serviceable as any to accomplish this purpose.² The *U. S. Pharm.* 1890 recognized only the purer salt, having dismissed *Sodii Bicarbonas Venalis*. Sodium bicarbonate must now contain 99 per cent. of the pure salt, and the quality of the commercial salt has greatly improved in late years.

Immense quantities of sodium bicarbonate were formerly imported from Great Britain, but the importation has fallen off, and is only trifling at the present time (1906). It is now made of excellent quality by the Pennsylvania Salt Manufacturing Co., at Natrona, Pa., using cryolite as raw material, and by the Solvay Process Co., of Geddes, near Syracuse, N. Y., using the ammonia-soda process. (See *Sodii Carbonas*.) The American production, in 1905, was 68,867 tons, valued at \$1,135,610.

In the United States Pharmacopœia of 1860 a process for making sodium bicarbonate was given, but it has since been abandoned, as the salt can be made much more economically on the large scale. The process consists in treating crystallized sodium carbonate, contained in suitable chambers, with carbon dioxide gas until the carbonate has taken up another molecule of carbon dioxide. It is formed by the union of neutral carbonate, Na_2CO_3 , with carbon dioxide gas, CO_2 , in the presence of water, H_2O , according to the following reaction:

two molecules of the bicarbonate being generated. The necessary water is obtained through the liberation of the water of crystallization of the carbonate; in fact, provision has to be made for the escape of the excess by placing the crystals upon perforated bottoms.

¹ *Sodium Boro-benzoate*.—According to Thos. S. Wiegand, this salt may be made by adding benzoic acid to a hot solution of borax to saturation and evaporating to dryness; or by making an aqueous solution of three ounces of borax and another with four ounces of sodium benzoate, mixing, and evaporating to dryness, the yield is about six ounces. The dose is from twelve to fifteen grains. (*A. J. P.*, 1884, p. 615.)

² "Take of Commercial Bicarbonate of Sodium, in powder, *sixty-four troy ounces*; Distilled Water, *six pints*. Introduce the powder into a suitable conical glass percolator, cover it with a piece of wet muslin, and pour the Water gradually upon it. When the liquid has ceased to drop, or when the washings cease to precipitate a solution of sulphate of magnesium, remove the Bicarbonate of Sodium from the percolator, and dry it on bibulous paper, in a warm place." *U. S.* 1870.

We are informed that crude sodium bicarbonate is also prepared in breweries, in the same manner as potassium bicarbonate or saleratus, by placing the carbonate in suitable vessels over the fermenting beer in the vats, so as to be constantly immersed in an atmosphere of carbon dioxide. It is sold under the same name as the analogous salt of potassium, but is usually distinguished as *soda sal aeratus*.

Properties.—The bicarbonate is officially described as “a white, opaque powder, odorless, and having a cooling, mildly alkaline taste. Permanent in dry, but slowly decomposed in moist air. Soluble in 12 parts of water at 15° C. (59° F.); above this temperature the solution gradually loses carbon dioxide, and at boiling heat the salt is entirely converted into normal carbonate; insoluble in alcohol. When heated, the salt is decomposed into normal carbonate, water, and carbon dioxide, and finally, at 100° C. (212° F.), loses about 36.9 percent. of its weight. At a bright red heat it melts. To a non-luminous flame it imparts an intense yellow color. The solution, when freshly prepared with cold distilled water, without shaking, gives a slightly alkaline reaction with litmus paper. The alkalinity increases by standing, agitation, or increase of temperature. With acids the solution effervesces strongly. If Sodium Bicarbonate be heated in a test-tube, no odor of ammonia should be evolved. If 1 Gm. of the salt be dissolved in 19 Cc. of water, it should yield a perfectly clear and colorless solution, leaving no residue. If 1 Gm. of the salt be dissolved without agitation in 20 Cc. of water, at a temperature not exceeding 15° C. (59° F.), and 0.2 Cc. of normal hydrochloric acid and 2 drops of phenolphthalein T.S. be added, a red tint should not appear immediately (limit of carbonate). If 5 Cc. of an aqueous solution (1 in 20) be slightly supersaturated with hydrochloric acid, the liquid should not be colored red by a drop of ferric chloride T.S. (absence of *sulphocyanate*). The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). Two Gm. of Sodium Bicarbonate should require for complete neutralization not less than 23.7 (23.74) Cc. of normal sulphuric acid V.S., methyl-orange T.S. being used as indicator.” *U. S.* “In powder or small opaque monoclinic crystals, white, of a saline taste, soluble in 11 parts of cold water. It affords the reactions characteristic of sodium and of bicarbonates. Each gramme should require for neutralization from 11.8 to 11.9 cubic centimetres of the *volumetric solution of sulphuric acid*. It should yield no characteristic reaction with the tests for lead, copper, iron, aluminium, calcium, magnesium, potassium, sulphites, or thiosulphates, and only the slightest characteristic reactions with the tests for chlorides, sulphates, or ammonium. A solution of the salt in cold water gives

a whitish precipitate, becoming brownish-red on standing, with *test-solution of mercuric chloride* (distinction from sodium carbonate). The addition of *test-solution of ferric chloride* to the aqueous solution acidulated with *hydrochloric acid* should cause no red coloration (absence of thiocyanates). 20 parts of Sodium Bicarbonate are neutralized by 16.7 parts of Citric Acid, and by 17.8 parts of Tartaric Acid.” *Br.* The salt furnished by the manufacturers almost always comes up to the requirements of the Pharmacopœias. The presence of carbonate may be known by a decided alkaline taste and reaction, by a cold solution of the salt yielding a precipitate with magnesium sulphate, and by a solution in 40 parts of water affording, without agitation, an orange-colored or reddish-brown precipitate with corrosive sublimate. The pure bicarbonate is not precipitated by platinic chloride, nor, when treated with nitric acid in excess, by barium chloride or silver nitrate. The non-action of these tests shows the absence of salts of potassium, and of sulphates and chlorides. For Wenzell's method of testing sodium bicarbonate, see *Proc. A. Ph. A.*, 1894, 277.

When the solution is exposed to heat, the salt gradually parts with carbon dioxide, and, at the temperature of 100° C. (212° F.), is converted into sesquicarbonate. At a red heat the second equivalent of carbon dioxide is expelled, and the anhydrous carbonate is left.

Sodium thiosulphate has been detected in small amount in European sodium bicarbonate by E. Mylius, who supersaturated the suspected bicarbonate in solution with sulphuric acid, and added a little pure zinc, when the odor of hydrogen sulphide was produced. A slight trace of arsenic was also discovered in the sodium bicarbonate. (*A. Pharm.*, 1886, p. 598.) F. B. Power subsequently examined samples of American bicarbonate, and found them all free from thiosulphate and arsenic; he detected, however, traces of chlorides, ammonia, and monocarbonate in the commercial salt. (*Ph. Rund.*, 1887, p. 35.) E. Kuhlmann recommends rosolic acid as the best test for detecting monocarbonate; if a small fragment be placed in a solution of sodium bicarbonate, the liquid remains perfectly colorless even after a quarter of an hour if the salt be pure; but if it contain from one to four per cent. of monocarbonate a rose-red color will be produced after a few moments, and *immediately* in the presence of larger quantities, rapidly changing them to purple-red. (*A. Pharm.*, 1887, p. 72.)

Uses.—This salt has the general medicinal properties of the carbonate, but, from its mild taste and its less irritating qualities, proves more acceptable to the palate and stomach. It is often resorted to in *calculous cases* characterized by excess of uric acid. The continued use of the carbonate in these cases is liable to induce phosphatic deposit after the removal of the uric acid. According to D'Arcet, who made the observation at the

springs of Vichy, this objection does not apply to the bicarbonate, especially when taken in carbonic acid water, for this salt, by its superabundant acid, has the power of maintaining the phosphates in solution even after the alkali has caused the uric acid to disappear. The same remark is applicable to potassium bicarbonate. Sodium bicarbonate has been given in *infantile croup*, with apparent advantage in promoting the expulsion of the false membrane, in the dose of a grain every five minutes, dissolved in milk and water. Lemaire has proposed it as an antiphlogistic remedy in the treatment of *pneumonia*, *membranous angina*, and *croup*, supposing it to act on the principle of removing from the blood the excess of fibrin which exists in that liquid in inflammation. Its utility in membranous angina has been confirmed by Marchal (de Calvi). According to Jeannel, the use of sodium bicarbonate lessens the sugar in the urine of diabetic patients.

Dose, for an adult, from ten grains to a drachm (0.65 to 3.9 Gm.), taken most conveniently in a glass of carbonic acid water. When given in angina, fifteen grains (1 Gm.) may be administered every half-hour in a table-spoonful of water.

SODII BISULPHIS. U. S.

SODIUM BISULPHITE

(sō'dī-i bī-sŭl'phīs)

$\text{NaHSO}_3 = 103.35$

"It should contain not less than 90 percent. of pure Sodium Bisulphite, and should be kept in a cool place, in small, completely filled, well-stoppered bottles." *U. S.*

Sulfite (Bi) de Soude, *Fr. Cod.*; Natrium Bisulfurosum; Doppelt-schwefligsaures Natron, *G.*

Sodium bisulphite is prepared by thoroughly saturating a concentrated solution of sodium carbonate or bicarbonate with sulphurous acid gas, and collecting the crystals which form upon the cooling of the liquid. As found in commerce, it usually contains sodium thiosulphate and sulphate, is not reliable, and will not respond to the official tests; even when kept in well-stoppered bottles it will readily lose its crystalline character and the

quantity of sulphurous acid gradually diminishes. The bisulphite, under the technical name of *leucogen*, is largely used in many industries. It serves as bleaching agent in washing wool, and in the steeping of grain, and in preserving meats and vegetable juices, because of its reducing and anti-fermentative character.

Properties.—It is officially described as in "opaque, prismatic crystals, or a granular powder, exhaling an odor of sulphur dioxide, and having a disagreeable, sulphurous taste. Exposed to the air, the salt loses sulphur dioxide, and is gradually oxidized to sulphate. Soluble in 3.5 parts of water, and in 70 parts of alcohol at 25° C. (77° F.); in about 2 parts of boiling water, and in 49 parts of boiling alcohol. When strongly heated, the salt decrepitates, emits vapors of sulphur and of sulphur dioxide, and leaves a residue of sodium sulphate. To a non-luminous flame it imparts an intense yellow color. Its aqueous solution gives an acid reaction with blue litmus paper. On the addition of hydrochloric or sulphuric acid, an aqueous solution of the salt evolves sulphur dioxide, which is recognized by its odor, and by its blackening a strip of paper dipped into mercurous nitrate T.S. and held over the escaping gas. If 1 Gm. of Sodium Bisulphite be dissolved in 10 Cc. of diluted nitric acid, and the solution heated sufficiently to expel the gases, the liquid should not become turbid (absence of *thiosulphate*). If 1 Gm. of the salt be dissolved in 20 Cc. of diluted hydrochloric acid, and heated sufficiently to expel the sulphur dioxide, the remaining solution, after being restored to its original volume, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If to 50 Cc. of tenth-normal iodine V.S., measured from a burette into a glass-stoppered vial (of about 100 Cc. capacity), 0.25 Gm. of finely powdered crystals of Sodium Bisulphite be added, the solution allowed to stand for about an hour, and shaken at frequent intervals, then the addition of not more than 6.45 Cc. of tenth-normal sodium thiosulphate V.S. should be required to decolorize the solution." *U. S.*

Uses.—The medicinal properties are those of the sulphites generally. (See *Sodii Sulphis*.)

Dose, five to ten grains (0.32 to 0.65 Gm.).

SODII BORAS. U. S. (Br.)

SODIUM BORATE [Borax]

(sō'dī-i bō'rās)

$\text{Na}_2\text{B}_4\text{O}_7 + 10\text{H}_2\text{O} = 379.32$

"It should contain in the uneffloresced condition not less than 99 percent. of pure sodium tetraborate, and should be kept in well-stoppered bottles." *U. S.* "This salt, sodium pyroborate, $\text{Na}_2\text{B}_4\text{O}_7 \cdot 10\text{H}_2\text{O}$, occurs *native*. It is also made artificially by neutralizing

native boric acid with sodium carbonate, or by boiling native calcium borate with solution of sodium carbonate." Br.

Borax, Br., P. G.; Sodæ Bīboras, Bīborate of Soda, Sodium Bīborate, Sodium Pyroborate, Sodium Tetra-borate; Natrium Bīboricum (Bīboracium), Boras Sodicus; Borate de Soude, *Fr. Cod.*; Borax, Bauracon, Sel de Perse, *Fr.*; Borax, Borssaures Natron, *G.*; Borato di sodio, *Borace, It.*; Borato sodico, *Borax, Sp.*

Borax was known to the ancients; but its chemical character was first ascertained by Geoffroy in 1732. It exists in nature, and may be obtained by artificial means. It occurs in several localities in Europe, in Peru, and in beds, associated with calcium borate, in the district of Iquique, in the republic of Ecuador. This mineral (*boronatrocalcite*), which has become an article of commerce, and is considerably used as a substitute for borax, contains, according to T. L. Phipson, 34 per cent. of water, 11.95 of soda, 14.45 of lime, 34.71 of boric acid, 1.34 of chlorine, 1.10 of sulphuric acid, 0.60 of silica, and 2 of sand, and may be considered as a compound essentially of one molecule of crystallized sodium borate and two molecules of calcium borate, with two molecules of water. It is said also to contain usually some iodine and bromine. (G. Sims.) Borax has long been known to occur in certain lakes of Thibet and Persia, from which it was obtained by spontaneous evaporation. It constituted the impure borax called in commerce *tincol*.

An abundant source of borax has been developed within the limits of the United States. The existence of a borax lake in California was first made known by J. A. Veatch, who visited it in September, 1856, and, upon examining its waters, found borax among its constituents. The borax lake is a small offset of a large sheet of water, called Clear Lake, which is situated in the midst of a volcanic region, about 36 miles from the Pacific, and about 100 miles north of San Francisco. The smaller lake is separated from the larger by a low ridge of volcanic materials loosely massed together. It is of variable dimensions according to the season, being sometimes dry, at other times filled with water to the extent of about a mile in length and half a mile in breadth. In September, 1863, the water, being analyzed by G. E. Moore, was found to contain in a gallon 2401.56 grains of solid matter, of which about one-half was common salt, one-quarter sodium carbonate, and the remainder chiefly sodium borate, equivalent to 535.08 grains of the crystallized bīborate to the gallon. The borax, being the least soluble of the saline constituents, from time to time, as the water becomes saturated, crystallizes out, and is deposited at the bottom of the lake, where it has accumulated in large quantities. The crystals of borax, from the minutest speck up to a diameter of two or three inches, intermixed with blue mud, form a layer at the bottom of the lake of variable thickness,—18 inches in one place

that was examined. This deposit forms an apparently inexhaustible supply of borax, for as fast as removed in one place it is deposited in another by crystallization from the water, which, supplied from the volcanic regions around, promises to continue furnishing the borax for an indefinite period. Already the lake has supplied large quantities of borax to commerce. Iron coffer-dams are sunk to the bottom of the lake, the water pumped out, and the mixed mud and crystals removed. The crystals are picked out, and the earth, which is strongly impregnated with borax, is lixiviated, and the solution thus obtained evaporated in boilers until crystals form. In 1868 operations practically ceased at Borax Lake, but were continued at the neighboring Hachin-hama Lake until 1873. At present the supply of American borax comes from the more easily worked deposits in the sandy deserts about Death Valley, southeast of Pyramid Lake, in Nevada, in the Slate Range district, San Bernardino Co., and the Saline Valley, Inyo Co., California. In order to reduce as much as possible the cost of transportation, the boraxes of the Pacific coast are made usually of high quality, and the so-called "boracic acid glass," one pound of which is equal to three pounds of ordinary borax, is prepared. For an interesting description of the Slate Range district, see *Chem. News*, 1886, 245. The most important deposits which are worked at present, 1906, in California are the *colemanite* (calcium borate) deposits twelve miles northeast of Daggett in the Mojave Desert. The formation (one hundred feet or more in width) has been traced for fully ten miles. The colemanite is readily dissolved by sodium carbonate solution, when the borax crystallizes out. The total production of borax in the United States for 1905, was 20,882 tons, valued at \$2,122,801.

The world's production of boric acid minerals for 1903 in metric tons, was as follows: *Calcium borate*.—United States, 31,235; Bolivia, 1,206; Chili, 15,734; Peru, 2,584; Turkey, 9000. *Crude boric acid*.—Italy, 2,583.

Preparation of Artificial Borax.—Large quantities of borax are now made for the European market by the direct combination of *native boric acid* with soda. The acid is found abundantly in the crater of Vulcano, one of the Lipari Islands, but principally in a volcanic region of Tuscany occupying a space of ten or twelve miles. Within this region are found numerous hillocks and fissures, the latter of which emit hot aqueous vapor containing boric acid and certain gases. Around one or several of these fissures a circular basin of masonry is built, which is filled with water and called a lagoon. By the jets of vapor constantly breaking through it, the water becomes gradually impregnated with boric acid and heated. A series of such lagoons are made to communicate with each other on the declivity of a hill, and the lowest to discharge itself into a reservoir, where the solution is

allowed to rest and deposit mechanical impurities. From this reservoir the solution is made to pass into leaden evaporating pans, heated by the natural vapor, where it receives sufficient concentration to fit it for being conducted into wooden tubs, where it is allowed to cool and crystallize. The crude acid, thus obtained, contains, on an average, 84 per cent. of boric acid, the impurities consisting chiefly of alum, the double ammonium and magnesium sulphate, and calcium sulphate. The seven works in the neighborhood of Castelnuovo in Tuscany, belonging to Count Larderel, were producing, in 1878, over three millions of kilogrammes. Vulcano yielded 4000 kilogrammes of boric acid yearly. The crude acid is converted into borax by dissolving it to saturation in a solution of sodium carbonate, heated by steam, and the liquor, after boiling, is allowed to stand for ten or twelve hours. It is then drawn off into wooden vessels lined with lead, where it crystallizes. The impure crystals thus obtained are refined by dissolving in water heated by steam, adding sodium carbonate to the solution, and crystallizing. The merit of introducing the process for obtaining artificial borax belongs to Cartier and Payen, who succeeded in establishing its manufacture in France. According to Veatch, boric acid exists in the sea water on the coast of California.

Another method of neutralizing the Italian boric acid is practised in England. Instead of combining the acid and alkali in solution, the manufacturer mixes the acid in a solid state with a proper proportion of soda ash, and exposes the mixture to the heat of a reverberatory furnace, provision being made for the collection of a large quantity of ammonia, which is always present in the crude acid and escapes during the process. The remaining operations are similar to those performed in the preparation of sodium carbonate from the cake. (*A. J. P.*, 1867, p. 339.)

Properties.—Borax is a white salt, occurring in "colorless, transparent, monoclinic prisms, or a white powder, inodorous, and having a sweetish, alkaline taste. Slightly efflorescent in warm, dry air. Soluble in 20.4 parts of water at 25° C. (77° F.), and in 0.5 part of boiling water; insoluble in alcohol; it is soluble in 1 part of glycerin at 80° C. (176° F.). When heated, the salt at first loses part of its water of crystallization, then melts, and, when further heated, swells up and forms a white, porous mass. At a red heat it loses all of its water of crystallization (47 percent.), and fuses to a colorless glass. To a non-luminous flame it imparts an intense yellow color. An aqueous solution (1 in 20) colors red litmus paper blue, and yellow turmeric paper reddish-brown. After being acidulated with hydrochloric acid, the solution colors blue litmus paper red; yellow turmeric paper remains unchanged at first, but on drying, becomes brownish-red, and this color is temporarily changed to bluish-black by moistening with ammonia

water. If a drop of the solution of Sodium Borate in glycerin be held in a non-luminous flame, a transient bright green color will appear. If a slight excess of diluted sulphuric acid be added to a hot, saturated, aqueous solution of the salt, shining, scaly crystals of boric acid will separate on cooling, which, when dissolved in alcohol and the liquid ignited, impart a green color to the flame. With 21 Cc. of water, 1 Gm. of Sodium Borate should yield a perfectly clear and colorless solution, leaving no residue. The aqueous solution (1 in 20) should not effervesce with acids (absence of carbonate or bicarbonate). The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). The aqueous solution (1 in 20) should not be rendered turbid by magnesia mixture (absence of phosphate). If 1 Gm. of the salt be dissolved in 20 Cc. of diluted sulphuric acid by the aid of heat, and 3 drops of indigo T.S. be added, the blue color should not be discharged after heating for ten minutes on a water-bath (absence of nitrate)." *U. S.* "Transparent colorless crystals, sometimes slightly effloresced, with a weak alkaline reaction; insoluble in alcohol (90 per cent.), soluble in 25 times its weight of cold, and in half its weight of boiling water. It dissolves in its own weight of glycerin. It turns turmeric paper brown. It colors flame intensely yellow. A hot saturated solution, when acidulated with any of the mineral acids, lets fall, as it cools, a scaly crystalline deposit of boric acid, the solution of which in alcohol (90 per cent.) burns with a green flame. Each gramme dissolved in 200 cubic centimetres of water should require for neutralization 5.2 cubic centimetres of the volumetric solution of sulphuric acid, using methyl orange as the indicator." *Br.* Above a red heat it melts into a limpid liquid, which, after cooling, concretes into a transparent solid, called *glass of borax*, much used as a flux in assays with the blowpipe. Borax has been found in the English market adulterated to the extent of 20 per cent. with sodium phosphate. This may be detected by exposing the suspected borax to the heat of a drying-room for a few hours, when the phosphate, if present, will effloresce, and may be picked out. Commercial borax is used as a flux in metallurgical operations; as the basis of the enamel so much applied to iron utensils, glazed brick, and much china, earthenware, and tiling; in the laundry with starch to impart a gloss to linen; by the meat packers of the United States (1000 tons yearly) as an antiseptic, and very largely in soaps and toilet preparations and in detergent powders.

Borax has the property of rendering cream of tartar very soluble in water, and forms a combination with it called *soluble cream of tartar*, which is sometimes used in medicine. This preparation attracts moisture from the air, and

is soluble in its own weight of cold and half its weight of boiling water. (See *Potassii Bitartras*.) R. F. Fairthorne states that borax is more soluble in water if sugar has been added to it. (*A. J. P.*, March, 1881.) Soluble cream of tartar may be made by substituting boric acid for the borax. *Boric acid soluble cream of tartar* was directed by the French Codex of 1837, and was made by the following formula. Four hundred parts of cream of tartar and 100 of the acid are dissolved in a silver basin, at the boiling temperature, in 2400 parts of water. The solution is kept boiling until the greater part of the water is consumed. The fire is then moderated, and the solution continually stirred while the evaporation proceeds. When the matter has become very thick, it is removed by portions, which are flattened in the hand, completely dried by the heat of a stove, powdered, and kept in well-stoppered bottles. This form of soluble cream of tartar is more soluble than that made with borax. According to E. Robiquet, in order to obtain soluble cream of tartar, made with boric acid, of good quality, it is necessary to use a large quantity of water, and to boil for a long time. By proceeding thus, the boric acid undergoes a molecular modification, equivalent to a change from the crystallized to the vitreous condition, and a preparation readily and totally soluble in cold water is insured. The product should not be powdered, but kept in large grains. (*J. P. C.*, xxi. 197.) Borax is incompatible with the salts of the alkaloids; in warm solution it decomposes hydrated chloral.

Composition.—Borax has the formula $\text{Na}_2\text{B}_4\text{O}_7 + 10\text{H}_2\text{O}$. It ordinarily crystallizes in monoclinic prisms, and contains ten molecules of water (*prismatic borax*); but a variety of the salt exists which crystallizes in octahedrons, and contains only five molecules of water (*octahedral borax*). The latter is obtained in the artificial production of borax by crystallizing from a concentrated solution at a temperature between 60° and 80° C. (140° and 176° F.). When a solution of borax is evaporated at 100° C. (212° F.), the salt is left as a transparent, amorphous, brittle mass, containing four molecules of water. (Schweitzer.)¹

Boric acid may be obtained artificially by decomposing a hot saturated solution of borax with sulphuric acid, which unites with the soda to form sodium sulphate and sets free the acid. As thus obtained it is in white, shining, scaly crystals, characterized by the property of imparting a light-green color to the flame of burning alcohol. Boric acid has the formula H_3BO_3 , and is now official. (See *Acidum Boricum*.)

¹ *Sodium borate* (neutral).—This soluble borate may be made by adding boric acid to a hot concentrated aqueous solution of sodium diborate or borax until it has a neutral reaction; the crystals which separate (sodium borate) have been erroneously described under the name sodium tetraborate. They are transparent, fragile, and glassy; it is found in commerce in glass-like masses. It is soluble in cold water, but more soluble (70 per cent.) in hot water.

Boron is a non-metallic element, which, like carbon, is found to exist in two allotropic states, designated amorphous, and crystallized boron, corresponding severally to amorphous carbon and to the diamond. Crystallized boron is very brilliant, and of different colors, from garnet-red to a nearly colorless honey-yellow. Its density is 2.68, and its hardness very great. Wöhler and Deville distinguished three varieties of crystals, containing from 2 to 4 per cent. of carbon, and one specimen, in addition to carbon, about 7 per cent. of aluminum. The hardest variety was as hard as diamond. (See *Chem. Gaz.*, 1857.)

Uses.—The actions of borax and of boric acid upon the animal system are identical. The effects of borax are, however, very feeble, Cyon having found that in daily doses of three drachms borax exerts no perceptible influence upon the dog. Nevertheless, in sufficient amount it is a depressing poison, having an influence upon the heart as well as upon the spinal centres, and a number of instances of poisoning from it have been reported. The symptoms have varied somewhat, but in most if not all of the cases there have been great depression of spirits, fall of bodily temperature, a very feeble pulse,—rapid or slow,—and an erythematous eruption accompanied with much swelling of the parts, and especially affecting the lower extremities, and followed by exfoliation; nausea, violent vomiting, and hiccough have been present in some cases; ecchymoses have been noted; the mind usually remains clear until late in the poisoning, but death has been preceded by coma, with disturbances of the respiration, and involuntary discharges. The continued use of borax has produced "*borism*," which is characterized by gastric irritation, a peculiar absence of fatty matter and of moisture from the skin, and various skin eruptions, especially eczema, reddish papules with squamous desquamating borders, seborrhœic acne, and scarlatiniform plaques.

Borax has been used internally in *dysmenorrhœa*, and as an oxytocic for a supposed specific influence upon the uterus, and has also been employed in the *uric acid diathesis*. Again, it has been highly commended in *epilepsy*, but in a careful test made on a large scale in the epileptic wards of the Philadelphia Hospital by H. C. Wood it was found to have little or no influence on that disorder.

Borax is an antiseptic of moderate power. According to the experiments of Sternberg, it is more efficient in preventing putrefaction than in destroying the organisms of disease. Walb found that a five per cent. solution of it would keep fibrin perfectly fresh for nineteen days. It has been used to a considerable extent in antiseptic surgery, and, being free, or nearly so, from irritating properties, may be applied in powder or in strong solution to *wounds, ulcers, abscesses*, etc. Wounds dressed in a dry manner with a lint which has been prepared by previously wetting with a hot saturated solu-

tion of borax and drying, are said to do extremely well. Its chief value in practical medicine grows out of its peculiar detergent, mildly stimulant, or alterative action upon the mucous membrane. In *aphthous ulceration*, *diphtheria*, and other *inflammations of the mouth*, crystals of it may be allowed to dissolve slowly in the mouth. Bouchut has highly recommended, in *infantile diarrhœa*, enemas made by dissolving from two to five drachms of borax in two fluidounces of water. Washing out the bladder with a saturated solution of boric acid or borax is most efficacious in *subacute* and *chronic cystitis*. The same solution has also been found very useful in *inflammations of the urethra and vagina*, especially when there is pruritic irritation, and even in *scaly diseases of the skin*. A solution in distilled water, from five to ten grains to an ounce, is often of great service in *conjunctivitis*. Borax should not be prescribed in dilute solution mixed with glycerin, as a reaction occurs, the liquid becoming acid to test-paper.

Dose, ten to twenty grains (0.6 to 1.3 Gm.).

SODII BROMIDUM. U. S., *Br.*

SODIUM BROMIDE

(sô'dî-i brô'mî-dûm)

NaBr = 102.24

"It should contain, when dried, not less than 97 percent. of pure Sodium Bromide, and should be kept in well-stoppered bottles." *U. S.* "Sodium Bromide, NaBr, may be prepared in the same manner as Potassium Bromide, sodium hydroxide being used in place of potassium hydroxide." *Br.*

Bromure de Sodium, *Fr. Cod.*; Natrium bromatum, *P. G.*; Natriumbromid, Bromnatrium, *G.*; Bromuro di sodio, *It.*; Bromuro sodico, *Sp.*

This salt contains a larger proportion of bromine than does potassium bromide, on account of the lower atomic weight of sodium, sodium bromide containing 77.62 per cent. of bromine, while potassium bromide contains 67.13 per cent. It is a trifle more soluble in water and alcohol. It may be made by the same process that is employed for potassium bromide, substituting sodium carbonate for potassium carbonate. According to Castelholz, it is best made by transforming bromine into ammonium bromide, separating any iodine present as iodide by crystallization from the mother waters, and decomposing the ammonium bromide with sodium carbonate. The solution should be evaporated by heating carefully. (*A. J. P.*, xlii. 509.)

Properties.—It occurs in "colorless or white, cubical crystals, or a white, granular powder, odorless, and having a saline, slightly bitter taste. The salt absorbs moisture from the air without deliquescing. Soluble in about 1.7

parts of water, and in 12.5 parts of alcohol at 25° C. (77° F.); in 0.8 part of boiling water, and in 11 parts of boiling alcohol. When heated to a bright red heat, the salt melts, and, at a somewhat higher temperature, slowly volatilizes without decomposition. To a non-luminous flame it imparts an intense yellow color. An aqueous solution (1 in 20) is neutral or shows a faintly alkaline reaction with red litmus paper. Silver Nitrate T.S. added to a concentrated aqueous solution produces a yellowish-white precipitate, insoluble in nitric acid and in a moderate excess of ammonia water. If 1 Gm. of the salt be dissolved in 10 Cc. of water and 0.1 Cc. of tenth-normal sulphuric acid V.S. be added, no color should be produced by the subsequent addition of a drop of phenolphthalein T.S., even after boiling (limit of *alkali*). If to 10 Cc. of the aqueous solution of the salt (1 in 20) 1 Cc. of chloroform be added, and then chlorine water which has been diluted with an equal volume of water be cautiously introduced, drop by drop, with constant agitation, the liberated bromine will dissolve in the chloroform, imparting to it a yellow to orange color, free from any violet tint (absence of *iodide*). The aqueous solution of Sodium Bromide (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If diluted sulphuric acid be dropped upon some of the powdered salt, no yellow color should appear at once (absence of *bromate*). Ten Cc. of the aqueous solution of the salt (1 in 20), when acidulated with hydrochloric acid, should not be rendered turbid by the addition of 1 Cc. of potassium sulphate T.S. (absence of *barium*). If 0.3 Gm. of the well-dried salt be dissolved in about 50 Cc. of water, and 2 or 3 drops of potassium chromate T.S. be added, it should require not less than 28.5 nor more than 30 Cc. of tenth-normal silver nitrate V.S. to produce a permanent red color." *U. S.* "Soluble in less than 2 parts of *water*, and in 16 parts of *alcohol* (90 per cent.). It affords the reactions characteristic of sodium and of bromides. Each gramme of the dry salt dissolved in *water* should require for complete precipitation not less than 95.8 nor more than 97.8 cubic centimetres of the *volumetric solution of silver nitrate*. It should yield no characteristic reaction with the tests for lead, copper, arsenium, iron, aluminium, zinc, calcium, magnesium, potassium, ammonium, carbonates, cyanides, bromates, or iodates, and only the slightest reactions with the tests for chlorides, iodides, or sulphates. *Test-solution of ferric chloride* should not cause a red coloration in the aqueous solution (absence of *thiocyanates*)." *Br.*

Uses.—The medicinal properties of sodium bromide are similar to those of potassium bromide, except that the sodium salt is much less depressant to the circulation.

Dose, fifteen grains to one drachm (1.0 to 3.9 Gm.).

SODII CARBONAS. Br.

SODIUM CARBONATE

(sô'di-I cār'bō-nās)

"Sodium Carbonate, $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$, may be obtained from sodium chloride, either by interaction with ammonium bicarbonate and subsequent ignition, or by its conversion into sodium sulphate and the action of heat on a mixture of the sulphate with carbon and calcium carbonate." Br.

Carbonate of Soda, Sal Soda, Washing Soda; Natrium Carbonicum, P. G.; Carbonas Sodicus, Sal Sodæ; Carbonate de Soude pur cristallisé, Fr. Cod.; Einfach Kohlensaures Natron, Kohlensaures Natron. Soda, G.; Carbonato di sodio, It.; Carbonato sodico cristallizado, Sp.

Sodium carbonate is official in the U. S. P. (8th Rev.) only as *Sodii Carbonas Monohydras*. (See page 1141.)

Before entering upon the consideration of sodium carbonate, we shall speak generally of the sources of the alkali soda. These may be divided into the natural and the artificial. The natural sources are the minerals of native soda, and certain marine plants which yield the alkali in their ashes; the artificial are certain salts which furnish it by chemical decomposition.

Native soda, sometimes called *natron*, is found chiefly in Hungary, Egypt, and South America, and exists in these countries either in the surface earth, which often exhibits a saline efflorescence, or in solution in small lakes, from which it is extracted by taking advantage of the drying up of the water during the heats of summer. The native soda from Egypt, called *trona*, is a *sesquicarbonate*; that from South America is less carbonated. Of these sources, the only one which retains any importance at the present day is Egyptian *trona*, of which some 5000 tons are annually shipped from Alexandria. Native soda, in the form of *sesquicarbonate*, has been found in a soda lake in the territory of the Nizam, in Hindostan. Barth, in his *Travels in Africa*, states that *natron* is largely collected on the shores of Lake Tehad, and in some other localities in Central Africa. A similar product exists abundantly in low places along the sea coast of Arabia, near Aden. (R. Haines, P. J., July, 1863.) Probably the most numerous and extensive natural soda deposits in the world exist in Southeastern Wyoming, in the counties of Albany, Carbon, and Natrona. The salts are the carbonate and sulphate, at times pure, and again as mixtures both hydrated and partly dehydrated. For a full account of these localities with analyses of different deposits, see *The Mineral Industry* for 1897, 612-616. New York, 1898.

Impure soda, derived from the ashes of plants growing on the surface or borders of the sea, is called *barilla* or *kelp*, according to the character of the plants incinerated. *Barilla* is ob-

tained from several vegetables, principally belonging to the genera *Salsola*, *Salicornia*, and *Chenopodium*. In Spain, Sicily, and some other countries these plants are cultivated for the purpose of yielding soda by their combustion. When ripe, they are cut down, dried, and burnt in heaps. The ashes form a semi-fused, hard, and compact saline mass, which is broken up into fragments by means of pickaxes, and introduced into commerce. Kelp, called *varec* in France, is procured by the incineration of various kinds of sea weeds, principally the algæ and fuci, which grow on the rocky coasts of many countries. The Orkneys and Hebrides, and the rocky coasts of Wales, Scotland, and Ireland, furnish large quantities of these weeds. The plants are fermented in heaps, then dried, and afterwards burnt to ashes in ovens roughly made of brick or stone and built in the ground. The alkali in the ashes melts, and forms the whole into a solid mass. When cold, it is broken up with iron instruments into large heavy masses, in which state it is found in commerce. About twenty-four tons of sea weeds produce one ton of kelp. *Barilla*, when of good quality, is in hard, dry, porous, sonorous, grayish-blue masses, which become covered with a saline efflorescence on exposure. It possesses a peculiar odor and an alkaline taste. *Spanish barilla* contains from 25 to 40 per cent. of carbonated alkali, the residue being made up of sodium sulphate, sodium sulphide and chloride, calcium carbonate, alumina, silica, oxidized iron, and a small portion of charcoal which has escaped combustion. Before the introduction of artificial soda, *barilla* formed the source of the crystallized carbonate employed in medicine. At present it is principally used in the manufacture of soap. *Kelp* is in hard, vesicular masses, of a dark-gray, bluish, or greenish color, a sulphurous odor, and an acrid, caustic taste. It is still less pure than *barilla*, containing only from 5 to 8 per cent. of carbonated soda, the rest being made up of a large proportion of sodium and potassium sulphates, and potassium and sodium chlorides, a small quantity of sodium iodide, and insoluble and coloring matters. Large quantities of kelp were formerly manufactured in Great Britain and the neighboring islands, particularly the Orkneys; but the demand and production have generally fallen off since the introduction of artificial soda. At present kelp is used principally in the manufacture of iodine. (See *Iodum*.)

Artificial Soda.—This is made from common salt by the older or Leblanc process in two steps; first, by converting the salt by sulphuric acid into sodium sulphate, and, secondly, by decomposing the sulphate by calcium carbonate and charcoal at a high temperature, so as to yield sodium carbonate. The chemical reactions may be summarized as follows:

The sulphate, first dried, is mixed with its own

weight of ground limestone, and half its weight of small coal, ground and sifted, and the whole is heated in a reverberatory furnace, which may be either stationary or, as is more general now, revolving on a horizontal axis. In this "black-ash furnace" the mixture fuses, and forms a black mass called *black ash*, *soda ball*, or *British barilla*. The coal, at the temperature employed, converts the sodium sulphate into sodium sulphide. This reacts with the limestone, so as to form calcium sulphide and sodium carbonate, Na_2S and $\text{CaCO}_3 = \text{CaS}$ and Na_2CO_3 . Black ash contains from 36 to 45 per cent. of alkali, imperfectly carbonated on account of the high temperature used, the remainder being principally calcium sulphide, caustic lime, sodium chloride, calcium sulphite, and coaly matter. It is next digested in warm water, which takes up the alkali and other soluble matters, and leaves the insoluble impurities, called *soda waste*, which is now largely utilized in the manufacture of sodium thiosulphate. The solution is evaporated to dryness, and the mass obtained is calcined with one-fourth of its weight of sawdust, in order to convert the alkali fully into carbonate, by means of the carbon dioxide resulting from the combustion of the sawdust. The product is redissolved in water, and the solution evaporated to dryness. The alkali, in this stage of its purification, contains about 50 per cent. of sodium carbonate, and is called *soda-ash*. It is brought to the state of crystallized sodium carbonate by dissolving it in water, straining the solution, evaporating it to a pellicle, and setting it aside to crystallize. This process was invented in 1784 by Leblanc, and the first manufactory for producing it on a large scale was established in 1790, near Paris, by Leblanc and Dizé. The process is pursued on an immense scale in Great Britain, especially in Liverpool and Glasgow. Various modifications have been proposed, and in part carried into practice, which affect the Leblanc process more or less fundamentally. One of the most important of these is the Hargreaves-Robinson method of preparing "salt-cake" or sodium sulphate without the previous preparation of sulphuric acid. Sulphur dioxide (from the roasting of pyrites), atmospheric oxygen, and steam are made to act upon salt previously prepared in broken cakes or fragments. Sodium sulphate and hydrochloric acid are obtained. The use of sodium nitrate is dispensed with, the sulphate is purer than that of the old method, and the hydrochloric acid is more easily condensed. It requires, however, a more expensive plant. A troublesome side-product of the Leblanc process is the calcium sulphide or "alkali waste," and much ingenuity has been used in endeavoring to utilize this and to recover the sulphur. The most successful sulphur recovery process thus far has been that of Chance, who decomposes the calcium sulphide by carbon dioxide, liberating H_2S . This is mixed with air and passed over a layer of ferric oxide, which at a low red heat causes the hydrogen to

burn, liberating the sulphur, which may either be collected or burned to SO_2 for the lead-chamber process. It is asserted that 95 per cent. of the sulphur can be thus recovered.

The Gossage process, still more recently proposed, aims to avoid the formation of the "alkali waste" altogether, and to do away with the black-ash furnace. By heating the salt cake with the necessary proportion of coal-slack the sodium sulphate is reduced to sodium sulphide. This is dissolved, allowed to settle, and the supernatant liquid, freed from silica and alumina, is conducted to towers, where it is treated with excess of carbon dioxide, whereby sodium bicarbonate and hydrogen sulphide are formed. The bicarbonate may be heated to change it into normal salt, while the carbon dioxide is utilized in decomposing fresh quantities of sulphide.

Within the last few decades a process has been put in practice which has given so much satisfaction in its results as to be likely to rival, if not to supersede, the hitherto unequalled process of Leblanc. It is designated the *ammonia-soda* process, and is based on the fact that when carbon dioxide is passed into a solution of common salt in aqueous ammonia a double decomposition occurs, and the slightly soluble sodium bicarbonate is precipitated:

From the mother liquor containing the sal-ammoniac, if deemed advisable, the ammonia may be withdrawn by the action of lime, and serve in the renewal of the operation. The sodium bicarbonate is reduced by heat to the carbonate, and the carbon dioxide thus obtained serves to convert the ammonia into the ammonium bicarbonate necessary in the proceeding. The waste product here is calcium chloride, which takes with it all the chlorine of the salt originally used. Therefore if the ammonia-soda process were to replace the Leblanc process, hydrochloric acid and chlorine would have to be made independently, and would become much dearer than at present. To obviate this objection to the ammonia-soda process and to produce hydrochloric acid as one product of the same process, the late Walter Weldon proposed to use magnesia instead of lime in the decomposing of the sal-ammoniac. This would leave magnesium chloride instead of calcium chloride. From the magnesium chloride the chlorine can be obtained as follows:

Steam will liberate hydrochloric acid from the magnesium chloride. This process is carried out practically at Salindres in France, although its economy is not definitely established.

A still more promising suggestion is that of the distinguished chemist Ludwig Mond of Brunner, Mond & Co., who are the chief English manufacturers of ammonia-soda. He proposes to freeze out the ammonium chloride from the mother liquors by artificial refrigeration, sublime it, and pass the vapor over magnesia, whereby

the hydrochloric acid is retained in combination with the magnesia as magnesium chloride, while the ammonia passes on. The magnesium chloride is then heated in a current of air, when it is split up into chlorine and magnesia.

The reaction between ammonium bicarbonate and sodium chloride, upon which the ammonia process was founded, was first discovered by Dyar and Hemming about 1838, but it was only in 1863 that Ernest Solvay, a Belgian chemist, made it a practical success. The advantages of this method are that the sodium chloride is directly transformed into sodium carbonate, that in the precipitation sodium is the only metal thrown down, and that the preparation is therefore remarkably pure, that it is entirely exempt from the compounds of sulphur, that the amount of product is very large, that the apparatus used is very simple, that there is a great saving of fuel and of labor, and, finally, that no unwholesome gases are diffused in the atmosphere, interfering with the health of the workmen and the community. Schloesing and Rolland have observed that in the double decomposition between ammonium bicarbonate and sodium chloride a certain portion only—about two-thirds—undergoes the change. This is explained by Bauer, who finds that the reaction is limited by another in an inverse direction. Thus, if ammonium bicarbonate and sodium chloride yield sodium bicarbonate and ammonium chloride (hydrochlorate of ammonia), these, put together, inversely yield ammonium bicarbonate and sodium chloride. An equilibrium is thus established, and the mixture preserves a constant composition, at the point where the two reactions take place at the same time. (*J. P. C.*, Sept. 1874.) At present the ammonia-soda process is gaining rapidly upon the Leblanc process. In England, the Leblanc process is most strongly entrenched and backed by the resources of the "United Alkali Company," a combination of manufacturers with a paid-up capital of \$42,000,000; this steady gain is shown by the following figures:

	1894. Tons.	1895. Tons.	1896. Tons.
Leblanc process	434,298	408,173	360,929
Ammonia-soda process	361,603	428,614	481,577
Total production	795,901	836,787	792,506

In 1900 the world's production of soda ash and caustic soda by the two processes was as follows: ammonia-soda product, 1,400,000 tons; Leblanc product 400,000 tons.

The production of alkali—reckoned at 58° soda ash—in the United States amounted to 386,361 tons in 1900, valued at \$4,768,383, and in 1905 to 518,954 tons, valued at \$8,204,545, all by the ammonia-soda process. The main producers were the Solvay Process Co. of Geddes, near Syracuse, N. Y., and the Michigan Alkali Co.

Another source of this carbonate has been discovered in *cryolite*, a mineral existing in great abundance on the coast of Greenland, and largely imported into this country by a

manufacturing company which enjoys to a certain extent a monopoly of the mineral under the Danish authorities. Cryolite consists mainly of a double aluminum and sodium fluoride, containing in 100 parts 13 of aluminum, 34 of sodium, and 53 of fluorine. Sodium carbonate is obtained by heating cryolite with lime, whereby calcium fluoride is formed, while the sodium and aluminum combine to form a sodium aluminate, a weak salt, which is dissolved out by lixiviation. The soda is converted into carbonate by passing carbon dioxide under pressure through the solution, and the alumina, separated from the soda, becomes insoluble, and is deposited. (*A. J. P.*, Jan. 1863, p. 71.) Cryolite is also largely used in Denmark and Germany in the preparation of sodium carbonate and of alumina, the latter of which is employed in the manufacture of alum and aluminum.

Besides the preparation of sodium carbonate, cryolite is employed for other important purposes. Within recent years it has become quite important as a flux for the electrolytic production of aluminum by the Hall and similar processes. (See *Alumen*.) Its only known locality, at least in large amount, is Greenland, where it is found on the southwest coast, near Cape Farewell, existing in beds, of which one is said to be eighty feet thick and three hundred long. It is imported by the "Pennsylvania Salt Manufacturing Company" into Philadelphia in immense quantities. It is a handsome mineral, hard, brittle, and translucent, sometimes almost transparent, but generally of a frosty whiteness, which probably suggested its name of *cryolite* or *kryolite*, from the Greek κρυος, *frost*. Though homogeneous in great degree, it exhibits here and there in its substance dark spots, sometimes mere specks, sometimes of considerable size, which appear to be crystalline centres of substances mixed with it at the time of solidification, such as galena, ferrous carbonate, copper and iron pyrites, etc.

The different kinds of impure sodium carbonate, whether barilla, kelp, or soda-ash, being exceedingly variable in composition, it is important to have a ready method of determining the quantity of real carbonated alkali which they contain. The mode in which this is done, is by means of an instrument called an alkalimeter, which is frequently used by analytical chemists. These various forms of carbonated soda are largely consumed in dyeing and bleaching, and in the manufacture of soap and glass. In reference to "the English commercial test," see *A. J. P.*, Sept. 1870, p. 447. The following are descriptions of the different grades of artificial soda, known under the names of British barilla, and soda-ash.

British barilla, so called to distinguish it from Spanish *barilla*, which has its source in the ashes of maritime plants, is a blackish-brown substance, becoming darker by exposure to the air. When broken it exhibits an imperfect metallic lustre, and a close striated texture. Its taste is alkaline and caustic. On exposure to a moist atmosphere it becomes covered with a yellow efflorescence, and quickly falls to powder, with disengagement of heat and hydrogen sulphide, the powder at the same time increasing in weight by the absorption of carbon dioxide and water.

Soda-ash is in white or gray masses, and contains about half its weight of foreign salts, consisting of sodium chloride and sodium sulphate.

Properties.—The carbonate according to the U. S. P. 1890 occurs in "colorless, monoclinic crystals, odorless, and having a strongly alkaline taste. In dry air the salt effloresces, and, if left exposed, soon loses about half of its water of crystallization (31.467 per cent. of its weight), and becomes a white powder. Soluble in 1.6 parts of water at 15° C. (59° F.), in 0.09 part at 38° C. (100.4° F.), and in 0.2 part of boiling water; insoluble in alcohol and in ether; soluble in 1.02 parts of glycerin. When heated at 32.5° C. (90.5° F.), the crystals fuse in their water of crystallization, and lose some water. At a higher temperature, the salt continues to lose water, until, at last, an anhydrous residue is left, corresponding to 37 per cent. of the weight of the crystals. At a bright red heat the anhydrous salt fuses. To a non-luminous flame it imparts an intense, yellow color. The aqueous solution gives an alkaline reaction with litmus paper, and effervesces strongly with acids. A 5 per cent. aqueous solution of the salt should be perfectly clear and colorless, leaving no insoluble residue. If 5 Cc. of the aqueous solution (1 in 20) be slightly supersaturated with hydrochloric acid, the liquid should not be colored red by a drop of ferric chloride test-solution (absence of *sulphocyanate*). If to 5 Cc. of the aqueous solution, slightly supersaturated with hydrochloric acid, an equal volume of hydrogen sulphide test-solution be added, no turbidity should be produced, either before or after the addition of ammonia water in slight excess (absence of *arsenic, lead, iron, aluminum*, etc.). If 5 Cc. of the aqueous solution be slightly supersaturated with acetic acid, the addition of 0.5 Cc. of ammonium oxalate test-solution should produce no turbidity (absence of *calcium*). If 5 Cc. of the aqueous solution be slightly supersaturated with acetic acid, the addition of 0.5 Cc. of sodium cobaltic nitrite test-solution should not render it turbid within one hour (limit of *potassium*). If 1.2 Gm. of the salt be dissolved in 10 Cc. of diluted nitric acid, then 0.5 Cc. of silver nitrate decinormal volumetric solution added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addi-

tion of silver nitrate volumetric solution (limit of *chloride*). If 2.5 Gm. of the salt be dissolved in 10 Cc. of diluted hydrochloric acid, then 0.1 Cc. of nitric acid and 0.1 Cc. of barium chloride test-solution added, and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of barium chloride test-solution (limit of *sulphate, sulphite, and hyposulphite*). If the crystallized salt be heated in a test-tube, the vapor of *ammonia* should not be evolved. To neutralize 1 Gm. of anhydrous Sodium Carbonate (deprived of its water of crystallization by heat immediately before being weighed) should require not less than 18.7 Cc. of normal sulphuric acid (corresponding to not less than 98.9 per cent. of the pure salt), methyl-orange being used as indicator." U. S. 1890. "In transparent colorless rhombic crystals, efflorescent, with a harsh taste and strong alkaline reaction, soluble in 2 parts of cold water. It should respond to the qualitative tests enumerated under '*Sodii Bicarbonas*,' except that its aqueous solution gives an immediate brownish-red precipitate with *test-solution of mercuric chloride*. When heated it liquefies and then dries up, losing 62.93 per cent. of its weight. Each gramme of the crystallized salt should require for neutralization at least 6.9 cubic centimetres of the *volumetric solution of sulphuric acid*. 20 parts of Sodium Carbonate are neutralized by 9.8 parts of Citric Acid, and by 10.5 parts of Tartaric Acid." Br.

This salt presents an anomaly in its solubility, as ascertained by Henri Loewel; it is more soluble in water at 36.1° C. (97° F.) than at its boiling point. Sodium carbonate is insoluble in alcohol. The most usual impurities in it are sodium sulphate and common salt, which may be detected by converting it into a nitrate and testing separate portions of this severally with barium chloride and silver nitrate.¹ Common salt is seldom entirely absent, but good specimens are free from sodium sulphate. When badly prepared it is liable to contain sodium sulphide, which may be detected by the production of the odor of hydrogen sulphide upon dissolving the salt in water. Sodium carbonate is incompatible with acids, which decompose it with effervescence, acidulous salts, lime water, ammonium chloride, and earthy and metallic salts. When crystallized it contains ten molecules of water. It is thus perceived that this salt, when crystallized, contains two-thirds of its weight of water; but the quantity actually present in it, as found in commerce, is variable, being dependent on the extent to which it may have undergone efflorescence. To obtain pure sodium carbonate for the purpose of a test, J. Lawrence Smith of Louisville, Ky., recommends that

¹For a method of determining the precise quantity of the sulphate in a special case, see J. P. G., Août, 1873, p. 124.

sodium oxalate should be prepared from the common carbonate, and then decomposed by heat.¹

Uses.—Soda being the natural alkali of the blood and other liquids of the human organism, its influence upon that organism in disease is very slight. In the experiments of Grædau the injection of 107 grains of sodium carbonate directly into the blood of a dog produced practically no symptoms, and in the studies of Münch upon the effect on the human system of the continuous exhibition for a few days of large amounts of soda the results were almost entirely negative. The chief influence of the salt is upon certain of the liquid excretions. Thus, the urine becomes distinctly alkaline, without, however, so far as we know, there being any distinct change in its general constituents. The experiments of Lewaschen prove that soda salts given to dogs with biliary fistula increase very markedly the liquidity of the bile and diminish the percentage of solids in it. These experiments are in accord with clinical experience, which shows that the alkaline sodium salts, given one to two hours after meals in full dose, are of decided value in the treatment of *gall-stones* and various affections associated with excessive acidity of the biliary secretion. On account of its having no general effect upon the system, soda and its carbonates are superior to potassium as simple alkaline remedies. When, therefore, it is desired to overcome *acidity of the stomach or intestines*, or to render acid urine alkaline, these preparations are very available; but they are not applicable in *gout, uric acid diathesis, rheumatism*, and occasionally in other diseases attended with *gastric acidity*, when it is desirable to bring about increased destruction of tissue and increased elimination of solids. Under these circumstances sodium salts are inferior to the potassium salts. Alkaline sodium salts are also employed with advantage, internally and externally, in *skin diseases*,

especially those of a papulous and scaly character. A lotion suitable for these cases may be formed by dissolving from two to three drachms of the carbonate in a pint of water. For a bath, from eight to sixteen ounces of the salt may be dissolved in the necessary quantity of water. In recent *burns* without much destruction of the skin, the free application of a saturated solution will usually give immediate relief. When swallowed in an overdose, it acts as a corrosive poison. The best antidotes are the fixed oils, acetic acid, and lemon juice.

Dose, from ten to thirty grains (0.65 to 2.0 Gm.).

SODII CARBONAS EXSICCATUS. Br.

EXSICCATED SODIUM CARBONATE

(sō'di-i cār'bō-nās ěx-sĭc-cā'tūs)

"Nearly anhydrous sodium carbonate, Na₂CO₃, which is obtained by heating Sodium Carbonate until it loses nearly 63 per cent. of its weight." Br.

Dried Carbonate of Soda; Exsiccated Sodium Carbonate; Carbonate de Soude sec du commerce, Fr. *Ord.*; Natrium carbonicum siccum, P. G.; Getrocknetes Natriumcarbonat, Entwässerte Soda, G.; Carbonato sodico seco, Sp.

"Sodium Carbonate, two hundred grammes [or 7 ounces av., 24 grains], to make one hundred grammes [or 3 ounces av., 231 grains]. Break the crystals into small fragments, and allow them to effloresce for several days in warm air, at a temperature not exceeding 25° C. (77° F.), until they are completely disintegrated; then dry the white powder at a temperature of about 45° C. (113° F.), until its weight is reduced to one hundred grammes [or 3 ounces av., 231 grains]. Pass the powder through a sieve, and preserve it in well-stoppered bottles." U. S. 1890.

Sodium carbonate contains ten molecules of water of crystallization, and, when heated, readily undergoes aqueous fusion. Upon continuing the heat, the water is driven off, and a white porous mass remains, which is easily reduced to powder. Dried sodium carbonate is in the form of a white powder, and differs in nothing from the crystallized, except in being devoid of water of crystallization. (See *Sodii Carbonas*.) It is officially described as "a loose, white powder, conforming to the reactions and tests given under *Sodii Carbonas*. To neutralize 1 Gm. of the salt should require not less than 13.8 Cc. of normal sulphuric acid (corresponding to about 73 per cent. of anhydrous Sodium Carbonate), methyl-orange being used as indicator." U. S. 1890. (See *Sodii Carbonas Monohydras*.)

Uses.—This preparation was introduced into practice by Beddoes, who extolled its virtues

¹Smith gives the following particular description of the method employed by him. 63 grammes of oxalic acid and 143 grammes of ordinary sodium carbonate are each dissolved, with heat, in 200 cubic centimeters of distilled water; the alkaline solution is filtered if necessary, and, when cool, the solution of oxalic acid, just hot enough to prevent crystallization, is added by degrees, with stirring. It is expected that the solution, when completed, shall have a slight alkaline reaction. Shortly after the operation is finished, the sodium oxalate will be in a great measure precipitated. The whole is then allowed to stand until completely cool; the supernatant liquid is decanted, a little distilled water added, and the lumps of crystals that may have formed are broken up by a stirrer, thrown on a six-inch filter over a Bunsen aspirator, washed with about half a liter of distilled water, and allowed to dry. The quantity of dry oxalate produced is 30 grammes. In this state it may be kept in a dry bottle until wanted for use in forming sodium carbonate. It is then projected, little by little, into a platinum capsule, over a good-sized Bunsen burner. After being strongly heated, the oxalate is changed by the decomposition of the oxalic acid into the carbonate, and, if the heat be high enough to fuse the salt, about 23 grammes of the fused carbonate will be obtained. Fused or not, this is dissolved in water, filtered, evaporated to dryness, dehydrated over a naked flame, and granulated by stirring while hot. (A. J. P., 1875, 31.)

in *calculous* diseases. It is applicable to the cure of such affections only when dependent on a morbid secretion of uric acid. Its advantage over the common carbonate is that it admits of being made into pills, in consequence of being in the dried state. As the water of crystallization forms more than half of the carbonate, the dose of the dried salt must be reduced in proportion. For the medicinal properties of this salt, see *Sodii Carbonas*.

Dose, two to ten grains (0.13 to 0.65 Gm.) may be given three times a day, in the form of pill prepared with soap and aromatics.

SODII CARBONAS MONOHYDRAS.

U. S.

MONOHYDRATED SODIUM CARBONATE

(sō'dī-i cār'bq-nās mō-nq-hy'drās)

"It should contain not less than 85 percent. of pure anhydrous Sodium Carbonate [$\text{CO}(\text{ONa})_2$], corresponding to not less than 99.5 percent. of the crystallized monohydrated salt."

U. S.

Preparation.—This salt was introduced into the U. S. P. (8th Rev.), upon the recommendation of Coblentz and Frerichs, on account of its much greater stability when compared with sodium carbonate; it contains but one molecule of water of crystallization, while the ordinary carbonate contains ten; as it is almost impossible to keep the carbonate without efflorescing, it became difficult to use it for chemical or pharmaceutical purposes without previously determining the quantity of water present. Coblentz ascertained by experiment that by exposure in an open vessel, monohydrated sodium carbonate gained the first week 0.14 per cent. of moisture, this increased to 0.16 per cent. by the second week. It is prepared by heating and crystallizing sodium carbonate at a temperature above 35°C . As it can be prepared commercially at a low price of excellent quality and is in the form of granular crystals its introduction into the Pharmacopœia will prove a great convenience. It may be used in the place of sodium carbonate.

Properties.—It is officially described as "a white, crystalline, granular powder, odorless, and having a strong alkaline taste. When exposed to the air, under ordinary conditions, it absorbs only a slight percentage of moisture; exposed to warm, dry air at or above 50°C . (122°F .) the salt effloresces, and at 100°C . (212°F .) it loses its water of crystallization (14.52 percent.). Soluble in 2.9 parts of water at 25°C . (77°F .), and in 1.8 parts of boiling water; insoluble in alcohol and in ether; soluble in 8 parts of glycerin. The aqueous solution shows an alkaline reaction with red litmus paper, and effervesces strongly with acids. To a non-luminous flame the solu-

tion imparts an intense yellow color. The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If 1 Gm. of Monohydrated Sodium Carbonate, or 0.855 Gm. of the anhydrous salt, be dissolved in 10 Cc. of distilled water, it should require not less than 32.3 Cc. of half-normal sulphuric acid V.S. for neutralization, 3 drops of methyl-orange T.S. being used as indicator." U. S.

Uses.—Monohydrated sodium carbonate can be used for the same purposes that sodium carbonate can, in the proportion of 1 of the former to 2.3 of the latter. (See *Sodii Carbonas*, page 1140.) For internal use it may replace the exsiccated sodium carbonate, being nearly identical with it in composition. (See *Sodii Carbonas Exsiccatus*, page 1140.)

Dose, two to ten grains (0.13 to 0.65 Gm.).

Off. Prep.—*Alumini Hydroxidum, U. S.*; *Extractum Ergotæ, U. S.*; *Liquor Sodæ Chlorinatæ, U. S.*; *Massa Ferri Carbonatis, U. S.*; *Spiritus Ætheris Nitrosi, U. S.*; *Suppositoria Glycerini, U. S.*

SODII CHLORAS. U. S.

SODIUM CHLORATE

(sō'dī-i çhlō'rās)

"It should contain not less than 99 percent. of pure Sodium Chlorate [ClO_3ONa]. This salt should be kept in well-stoppered bottles, and great caution should be observed in handling it, as dangerous explosions are liable to occur when it is heated, or subjected to concussion or trituration with organic substances (cork, tannic acid, sugar, etc.), or with sulphur, antimony sulphide, phosphorus, or other easily oxidizable substances." U. S.

Natrium Chloricum; Chlorate de Soude, Fr. Cod.; *Natriumchlorat, Chlorsaures Natron, G.*; *Clorato sodico, Sp.*

This official salt, while manufactured on a large scale for use in the textile industries by the method described under *Potassii Chloras*, is usually prepared on a small scale by Wittstein's process, which consists in first preparing sodium bitartrate by adding a strong solution containing 9.5 parts of tartaric acid to a hot aqueous solution of 9 parts of sodium carbonate. The hot solution is mixed with one in which 8 parts of potassium chlorate have been dissolved. Potassium bitartrate separates, while sodium chlorate remains in solution. The filtered solution is evaporated and crystallized. If desired of absolute purity, it may be recrystallized from an alcoholic solution. Owing to the facility with which this salt parts with its oxygen, the official cautionary direction should be borne in mind.

Properties.—It is officially described as in "colorless, transparent crystals (principally

cubes with tetrahedral facets), or a crystalline powder; odorless, and having a cooling, saline taste. Permanent in dry air. Soluble in about 1 part of water, and in about 100 parts of alcohol at 25° C. (77° F.); in 0.5 part of boiling water, and in about 40 parts of boiling alcohol; also soluble in about 5 parts of glycerin. When heated, the salt melts, then gives off oxygen (about 45 percent. of its weight), and finally leaves a residue of sodium chloride, readily soluble in water, and yielding, with silver nitrate T.S., a white, curdy precipitate, insoluble in nitric acid. To a non-luminous flame it imparts an intense yellow color. An aqueous solution of Sodium Chlorate (1 in 20) is neutral to litmus paper. When a crystal of the salt is dropped into hydrochloric acid, the liquid assumes a deep greenish-yellow color, and emits the odor of chlorine. A saturated, aqueous solution should not be rendered turbid by sodium bitartrate T.S. (limit of *potassium*). The aqueous solution of the salt (1 in 20), upon the addition of 1 Cc. of ammonium sulphide T.S., should not develop a dark coloration (absence of *lead*, *copper*, etc.)" *U. S.*

Uses.—Sodium chlorate has medicinal properties similar to those of potassium chlorate, while its greater solubility permits the use of stronger solutions. According to Brissaud, when given in daily doses of more than two drachms it is apt to produce albuminuria. In overdose it would probably cause symptoms not distinguishable from those caused by potassium chlorate poisoning.

Dose, five to fifteen grains (0.32 to 1.0 Gm.).

SODII CHLORIDUM. U. S., Br.

SODIUM CHLORIDE

(sō'dī-ī phlō'rj-dūm)

NaCl = 58.06

"It should contain when dried not less than 99 percent. of pure Sodium Chloride." *U. S.*

This mineral production, so necessary to mankind, is universally distributed over the globe, and is the most abundant of the native soluble salts. Most animals have an instinctive relish for it, and, from its frequent presence in the solids and fluids of the animal economy, it may be supposed to perform an important part in assimilation and nutrition.

Natural state.—Common salt exists in nature either in the solid state or in solution. In the solid state, called *rock salt*, *fossil salt*, and *sal gemma*, it is often found forming extensive beds, and even entire mountains,

from which it is extracted in blocks or masses by mining operations. Its geological position is very constant, it occurring almost invariably in secondary formations, associated with clay and gypsum. In solution it exists in certain springs and lakes, and in the waters of the ocean. The principal salt mines are found in Poland, Hungary, and Russia; in various parts of Germany and Austria, particularly the Tyrol; in Cheshire, England; in Spain; in various parts of Asia and Africa; in Turk's island near St. Domingo; and in Peru and other countries of South America. There are but few mines in the United States where rock salt is produced,—at present, one in Louisiana, two in Kansas, and a group operated by one company in the western part of the State of New York; but there are numerous salt springs, which either flow naturally or are produced artificially by sinking wells to various depths in places where salt is known to exist. These are found principally in Missouri, Kentucky, Illinois, Ohio, Michigan, Pennsylvania, Virginia, West Virginia, and New York. In the last-mentioned State the springs are the most productive, the chief ones being situated at Salina, Montezuma, and Galen. In West Virginia an important salt region exists, extending fifteen miles on both sides of the Great Kanawha River, and in Michigan in the counties of Huron, Bay, Wayne, and Saginaw extensive salt wells are worked. The production of salt in the United States in 1904 was 22,030,002 barrels of 280 lbs. each, valued at \$6,021,222. Nearly 90 per cent. of this was evaporated from brine, the remainder being the rock salt product.

Rock salt is always transparent or translucent; but it often exhibits various colors, such as red, yellow, brown, violet, blue, etc., which are supposed to be derived from iron and manganese.

Extraction.—Mines of salt are worked in two ways. When the salt is pure, it is merely dug out in blocks and thrown into commerce. When impure, it is dissolved in water, and extracted afterwards from the solution by evaporation. When the salt is naturally in solution, the mode of extraction depends upon the strength of the brine and the temperature of the place where it is found. When the water contains from 14 to 15 per cent. of the salt, it is extracted by evaporation in large iron boilers. If, however, it contains only 2, 3, 4, or 5 per cent., the salt is obtained in a different manner. If the climate be warm, it may be procured by spontaneous evaporation, effected by the heat of the sun; if temperate, by a peculiar mode of evaporation, to be mentioned presently, and the subsequent application of artificial heat.

Sea water is a weak saline solution, containing 2.7 per cent. of common salt, which is extracted by the agency of solar heat in warm countries. Salt thus obtained is called *bay salt*. The extraction is conducted in Europe

principally on the shores of the Mediterranean, the waters of which are salter than those of the open ocean. The mode in which it is performed is by letting the sea water into shallow dikes, lined with clay, and capable, after having been filled, of being shut off from the sea. In this situation the heat of the sun gradually concentrates the water, and the salt is deposited. About 30,000 tons a year are thus made at Alameda, California, the only place in the United States where solar evaporation is carried out. In temperate climates, weak brines are first concentrated in buildings called *graduation houses*. These are rough wooden structures open on the sides, ten or eleven yards high, five or six wide, and three or four hundred long, and containing an oblong pile of brushwood somewhat smaller than the building itself. The brine is pumped up into troughs full of holes, placed above the brushwood, upon which it is allowed to fall, and in its descent it becomes minutely divided. This operation, by greatly increasing the surface of the brine, promotes its evaporation; and, being repeated several times, the solution is at last brought to the requisite degree of strength to permit of its final concentration in iron boilers by artificial heat.

Properties.—Sodium chloride is white, without odor, and of a peculiar taste called saline. It is usually crystallized in cubes; but by quiet evaporation it often assumes the form of hollow quadrangular pyramids, or hopper-shaped crystals, consisting of an aggregation of cubes. It is officially described as in "colorless, transparent, cubical crystals, or a white, crystalline powder, odorless, and having a purely saline taste. Permanent in dry air. Soluble in 2.8 parts of water at 25° C. (77° F.), and in 2.5 parts of boiling water; almost insoluble in alcohol. When heated, the salt decrepitates. At a red heat it fuses, and at a white heat it is slowly volatilized and partly decomposed. To a non-luminous flame it imparts an intense yellow color. An aqueous solution of the salt is neutral to litmus paper. With silver nitrate T.S. the solution yields a white, curdy precipitate, insoluble in nitric acid, and readily soluble in ammonia water. The aqueous solution of Sodium Chloride (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If 2 Gm. of the finely powdered salt be digested for some hours with 25 Cc. of warm alcohol, and, after cooling, the undissolved salt be removed by filtration, the filtrate evaporated to dryness, and the residue dissolved in 5 Cc. of water, and if 1 Cc. of chloroform be added, and chlorine water which has been diluted with twice its volume of water, cautiously introduced, drop by drop, with constant agitation, the chloroform should not acquire a violet, yellow, or orange color (absence of *bromide* and *iodide*). If 1 Gm. of well-dried Sodium Chloride be dissolved in sufficient distilled water to measure 100 Cc.,

and 10 Cc. of the solution be mixed with a few drops of potassium chromate T.S., it should require not less than 17 (17.05) Cc. of tenth-normal silver nitrate V.S. to produce a permanent red color." *U. S.* "In small white crystalline grains or transparent cubic crystals, free from moisture, with a purely saline taste, soluble in less than 3 parts of *water*. It affords the reactions characteristic of sodium and of chlorides. It should yield no characteristic reaction with the tests for potassium, bromides, or iodides, and only slight reactions with the tests for calcium, magnesium, or sulphates." *Br.* When pure, it undergoes no change in the air; but when contaminated with magnesium chloride, as not unfrequently happens, it is deliquescent. Exposed to a gradually increasing heat, it first decrepitates from the presence of interstitial moisture, next melts, and finally volatilizes in white fumes with but partial decomposition. (Mulder, *J. P. C.*, 4e sér., iii.) It is decomposed by several of the acids, particularly sulphuric and nitric, which disengage vapors of hydrochloric acid; by potassium carbonate with the assistance of heat; and by silver nitrate and mercurous nitrate. In contact with iron, in the presence of air and moisture, it undergoes decomposition. (*Chem. News*, June, 1869.) It is decomposed by steam excessively heated, with the escape of hydrochloric acid and an alkaline residue. (*Chem. News*, June 4, 1875.) Several varieties of common salt are distinguished in commerce, as *stored salt*, *fishery salt*, *bay salt*, etc.; but they are characterized by the size and compactness of the grains, and not by any difference in composition.

Composition.—Common salt, in its pure state, consists of one atom of chlorine and one of sodium. It contains no water of crystallization. The common salt of commerce, besides pure sodium chloride, contains, generally speaking, insoluble matter, and usually more or less of calcium and magnesium sulphates and calcium and magnesium chlorides. When pure, it is not precipitated by sodium carbonate, barium chloride, or potassium ferrocyanide. Calcium chloride is generally present in very small amount; but the magnesium chloride sometimes amounts to 28 parts in 1000. Calcium sulphate is usually present, constituting variously from 1 to 23½ parts in 1000, and magnesium sulphate is sometimes present and sometimes absent. To separate the earths, a boiling solution of sodium carbonate must be added as long as any precipitate is formed. The earths will form as carbonates, and must be separated by filtration, and the sodium sulphate and sodium chloride resulting from the double decomposition will remain in solution. The sodium sulphate may then be decomposed by the cautious addition of barium chloride, avoiding excess, which will generate sodium chloride and insoluble barium sulphate.

Uses.—Sodium chloride, in small doses, acts as a stomachic tonic and anthelmintic, in larger

ones as a purgative and emetic. From the experiments of Buchheim, it appears that common salt quickly passes into the blood, and is thrown off in greater part, in six hours, by the kidneys. The portion not found in the urine and fæces is probably appropriated to the uses of the economy. Plouviez, as the result of experiments made upon himself, came to the conclusion that the use of a saline regimen has the effect of increasing the number of the red blood corpuscles as well as the weight and strength of the body. This is, however, contradicted by the more recent experiments of Münch, and the common experience of mankind seems to show that, while the habitual use of a certain amount of the salt is necessary for health, over-use of it has no effect in producing plethora.

Common salt has been used with good effect by a number of practitioners as a remedy in *intermittent fever*. It is not alleged to be equal to quinine. The dose is from eight to twelve drachms (31 to 46.5 Gm.), given in divided doses during the apyrexia. It is best administered in mucilage of slippery elm, or in coffee. In *hemoptysis*, common salt, in the dose of a teaspoonful (3.9 Gm.), taken dry, often proves successful in stopping the flow of blood. Externally applied in solution it is stimulant, and may be used either locally or generally. Locally, it is sometimes employed as a fomentation in *sprains and bruises*, and as a general external application it forms the salt water bath, a valuable remedy as a tonic and excitant in depraved conditions of the system, especially when occurring in children. A pound of salt dissolved in four gallons of water forms a solution of about the strength of sea water, and suitable for a bath. A 0.9 per cent. solution is largely used under the name of *physiological or normal salt solution in shock and hemorrhage*.

The uses of common salt in domestic economy as a condiment and an antiseptic are well known. In pharmacy it is employed to prepare chlorine, hydrochloric acid, ammonium chloride, calomel, and corrosive sublimate. It is also used to form sodium sulphate, with a view to its conversion into sodium carbonate.

Dose, as a cathartic, from two drachms to half an ounce (7.7 to 15.5 Gm.); as an emetic, from half an ounce to an ounce (15.5 to 31 Gm.), dissolved in four or five times its weight of water. It is frequently used as a clyster, two tablespoonfuls in a pint of water.

SODII CITRAS. U. S.

SODIUM CITRATE

(sô'di-i cî'trās)

"It should contain not less than 97 percent. of pure Sodium Citrate $[\text{2C}_6\text{H}_4(\text{OH})(\text{COONa})_3 + 11\text{H}_2\text{O}]$, and should be kept in well-stoppered bottles." U. S.

Citrate of Soda; Citras Sodicus; Citrate de Soude. Fr.; Natrium Citricum; Natriumcitrat, Citronsaures Natron, G.

Preparation.—This salt may be made by adding to a hot aqueous solution of 59 parts of citric acid an aqueous solution of 53 parts of monohydrated sodium carbonate, neutralizing, evaporating, and crystallizing.

Properties.—It is officially described as "a white, granular powder, odorless, and having a cooling, saline taste. It slowly effloresces on exposure to dry air. Soluble in 1.1 parts of water at 25° C. (77° F.), and in 0.4 part of boiling water; slightly soluble in alcohol. When heated to about 150° C. (302° F.) the salt loses all of its water of crystallization; on ignition at a red heat it decomposes and a mixture of sodium carbonate and carbon is left, which has an alkaline reaction and strongly effervesces with acids. To a non-luminous flame the salt imparts an intense yellow color. An aqueous solution of Sodium Citrate (1 in 20) is slightly alkaline to red litmus paper. The addition of 2 Cc. of calcium chloride T.S. to 10 Cc. of the aqueous solution of the salt (1 in 20) yields a clear solution, which, upon boiling, deposits a white, granular precipitate. The aqueous solution (1 in 20) should not be colored red by a drop of phenolphthalein T.S., nor effervesce on the addition of an acid (absence of carbonate). The aqueous solution of the salt (1 in 20), slightly acidulated with acetic acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If 1 Gm. of Sodium Citrate be thoroughly carbonized at a temperature not exceeding red heat, and the residue extracted with boiling distilled water, until the washings cease to react with methyl-orange T.S., the mixed filtrate and washings should require for complete neutralization not less than 16.4 (16.41) Cc. of half-normal sulphuric acid V.S., methyl-orange T.S. being used as indicator." U. S.

Sodium citrate may be used for the same purposes as potassium citrate (see *Potassii Citras*).

Dose, from fifteen to sixty grains (1.0 to 3.9 Gm.).

Off. Prep.—Syrupus Hypophosphitum Compositus, U. S.

SODII CITRO-TARTRAS EFFERVESCENS. Br.

EFFERVESCENT SODIUM CITRO-TARTRATE

(sô'di-i cî'trô-târ'trās êf-fêr-vēs'cens)

"Sodium Bicarbonate, in powder, 51 ounces (Imperial) or 510 grammes; Tartaric Acid, in powder, 27 ounces (Imp.) or 270 grammes; Citric Acid, in powder, 18 ounces (Imp.) or 180 grammes; Refined Sugar, in powder, 15 ounces (Imp.) or 150 grammes. Mix the powders thoroughly; place the mixture in a dish or pan of suitable form heated to between 200° and 220° F. (93.3° and 104.4° C.). When the mixture, by aid of careful manipulation, has assumed a granular character, separate it into granules of uniform and convenient size by

means of suitable sieves. Dry the granules at a temperature not exceeding 130° F. (54.4° C.). The product should weigh about 100 ounces (Imp.) or 1000 grammes." *Br.*

The object of this combination is to furnish sodium citrate and tartrate in a convenient and portable form. As the water has been driven off by heat, no reaction takes place until dissolved in water, when the two acids combine with the soda of the bicarbonate to produce sodium tartrate and citrate, and the carbon dioxide escapes with brisk effervescence. It is in this form that the preparation is intended to be used. The salts combine laxative with refrigerant properties, which adapt them to the *febrile state*, while the carbonic acid renders them acceptable to the stomach, and will often check *nausea* and *vomiting*.

Dose, one to two drachms (3.9 to 7.7 Gm.), which may be taken in a small wineglassful or more of water, and repeated occasionally as required.

SODII HYDROXIDUM. U. S., Br.

SODIUM HYDROXIDE [Sodium Hydrate, Caustic Soda, Soda, Pharm. 1890]

(sō'dī-i hŷ-drōx'ī-dŭm)

NaOH = 39.76

"It should contain not less than 90 percent. of pure anhydrous Sodium Hydroxide, and not more than 2 percent. of other inorganic substances, with the exception of water. It should be kept in well-stoppered bottles made of hard glass." *U. S.*

Soda Caustica; Hydrate of Soda; Natrium Causticum, s. Ilydricum; Soude caustique, *Fr. Cod.*; Natron, Aetzatron, *G.*; Soda caustica, *It.*; Hidrato sodico, *Sp.*

"Take of Solution of Soda *two pints*. Boil down the solution rapidly, in a silver or clean iron vessel, until there remains a fluid of oily consistence, a drop of which when removed on a warmed glass rod solidifies on cooling. Pour the fluid on a clean silver or iron plate, or into moulds, and, as soon as it has solidified, break it in pieces, and preserve it in stoppered green glass bottles." *Br.* 1885.

The Solution of Sodium Hydroxide, being a solution of the caustic alkali, yields it on evaporation in the solid state. Metallic vessels are used in consequence of the chemical action of soda on earthenware or porcelain, and the product is directed to be kept in green glass bottles because these resist its action better than those of white glass. Sodium hydroxide is usually poured into cylindrical moulds to harden, or allowed to solidify in mass, and broken into irregular fragments.

"The sodium hydroxide, sodium hydrate, or 'caustic soda,' of commerce, occurs in hard grayish-white rods or cakes, deliquescent, very alkaline and corrosive. It affords the reactions characteristic of sodium. It usually contains

as impurities alumina, carbonates, chlorides, phosphates, silicates, and sulphates. A clear solution of caustic soda may be used, instead of a solution of *Purified Sodium Hydroxide*, in all analytical operations in which the foregoing impurities would not vitiate the result.

Purified Sodium Hydroxide may be obtained by dissolving caustic soda in ethylic alcohol, filtering the solution, evaporating it to dryness in a silver dish, occasionally adding distilled water during the evaporation. The residue is *Purified Sodium Hydroxide*. It should yield no characteristic reaction with the tests for phosphates or sulphates, and not more than the slightest reactions with the tests for carbonates. It is not quite free from alumina.

Pure Sodium Hydroxide may be prepared by the interaction of pure barium hydroxide and sodium sulphate, or by the interaction of pure sodium and water. A solution of *Pure Sodium Hydroxide* is required only in testing for small quantities of aluminium." *Br.* 1898, *Appendix*.

Sodium hydroxide has been made on a large scale by simply modifying the Leblanc process (see *Sodii Carbonas*), so that more coal is added in the black-ash fusion, when carbonate is reduced to hydroxide with the liberation of carbon monoxide by the action of the quick-lime, the reactions being:

It is also made like the corresponding compound, caustic potash, by the decomposition of sodium carbonate in solution by quick-lime. (See *Liquor Sodii Hydroxidi*.) It may also be purified from carbonate, and from lime salts and other impurities, as the potassium hydroxide is purified by treatment with alcohol, which dissolves the alkali, but leaves the salts insoluble. (See *Sodii Carbonas*, page 1136.) Chemically pure sodium hydroxide can be made with commercial success from metallic sodium. The sodium is oxidized in water, using small pieces in succession, and keeping the temperature from rising too high. So obtained it is free from sodium chloride and sulphate, and from alumina, silica, and ferric oxide. (*A. J. P.*, xlii. 50.) Klas Lindroth obtained a product containing a mere trace of carbonate and chloride by evaporating the solution of impure sodium hydroxide until it has a sp. gr. of 1.375, and allowing it to crystallize at a temperature of 17° F. (*A. J. P.*, xlv. 106.) The manufacture of caustic soda in the United States has developed very greatly within the last few years, it being manufactured in connection with soda ash at the works of the Solvay Process Co., of Syracuse, New York, and Detroit, Michigan, and the Michigan Alkali Co., at Wyandotte, Michigan, and electrolytically at Niagara Falls by the Matthiessen Alkali Co. The importations of caustic soda are therefore decreasing, and will probably soon cease entirely; they amounted to 33,000 tons in 1897, but had di-

minished to 1500 tons in 1904. The American production for 1904 amounted to 80,173 tons, valued at \$2,924,850.

Properties.—It is officially described as “dry, white flakes, fused masses, or translucent or opaque white pencils, showing a crystalline fracture, odorless, and having a caustic taste. *Great caution is necessary in tasting and handling it, as it rapidly destroys organic tissues.* Exposed to the air, it rapidly deliquesces, absorbs carbon dioxide, and becomes covered with a dry coating of carbonate. Soluble in about 1 part of water at 25° C. (77° F.), and in 0.8 part of boiling water; very soluble in alcohol. When heated to about 525° C. (977° F.), Sodium Hydroxide melts to a clear, oily liquid, and at a bright red heat it is slowly volatilized unchanged. When introduced into a non-luminous flame, it imparts to it an intense yellow color. A solution of Sodium Hydroxide, even when greatly diluted, gives an alkaline reaction with red litmus paper. The aqueous solution (1 in 20) should be perfectly clear and colorless (absence of *organic matter and insoluble impurities*), and after being acidulated with acetic acid, it should yield no precipitate on the addition of an excess of tartaric acid T.S. (limit of *potassium*). The aqueous solution of Sodium Hydroxide (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). On adding a slight excess of diluted sulphuric acid to 10 Cc. of an aqueous solution of Sodium Hydroxide (1 in 10), no distinct effervescence should occur (limit of *carbonate*). If 0.7 Gm. of Sodium Hydroxide be dissolved in 1.5 Cc. of water, and the solution added to 10 Cc. of alcohol, not more than a slight, white precipitate should occur within ten minutes (limit of *silicate*, etc.). Introduce about 1 Gm. of Sodium Hydroxide into a stoppered weighing-bottle, and weigh accurately. Dissolve this in about 50 Cc. of water, and titrate the solution with normal sulphuric acid V.S., using methyl-orange T.S. as indicator. Multiply the number of Cc. of the normal sulphuric acid V.S. consumed, by 3.976, and divide this product by the weight of the Sodium Hydroxide taken; the quotient represents the percentage of Sodium Hydroxide present.” *U. S.*

As prepared by the Br. 1885 process, sodium hydroxide is in grayish-white fragments, opaque, brittle, and extremely corrosive. It is deliquescent, very soluble in water, soluble in alcohol, and possessed of all the alkaline properties of potassium hydroxide, from which it differs in imparting a yellow color to flame, and in not giving in solution a yellow precipitate with platonic chloride or a crystalline precipitate with tartaric acid in excess. When heated it melts, and at an intense heat evaporates. Though deliquescent, like potassium hydroxide, it does not, like that alkali, become permanently liquid, but forms a paste, which after a time effloresces. The difference in this respect between the two

alkalies is owing to the circumstance that, while both are converted into carbonates by uniting with the carbon dioxide of the air, potassium hydroxide forms a deliquescent and sodium hydroxide an efflorescent salt. It is apt to contain 20 or 25 per cent. of water and impurities originating from the sodium carbonate used in preparing the solution from which it is made. The official volumetric assay permits the presence of 10 per cent. of water and impurities, but limits the fixed impurities to 2 per cent.

If the solution be colored brown by hydrogen or ammonium sulphide, the presence of lead may be suspected, derived probably from the glass vessels in which it has been kept. It is used externally as a caustic in the same manner as potassium hydroxide, when cast into sticks. It has the advantage of being less deliquescent, and is probably milder.¹ It may be used also for making the solution of sodium hydroxide extemporaneously. (See *Liquor Sodii Hydroxidi*.) For the general effects of sodium hydroxide upon the system, see *Sodii Carbonas*, page 1140.

Off. Prep.—Antimonium Sulphuratum, *Br.*; Benzinum Purificatum, *U. S.*; Hydrargyri Oxidum Flavum, *U. S.*; Liquor Sodii Hydroxidi, *U. S.*

SODII HYPOPHOSPHIS, U. S., Br.

SODIUM HYPOPHOSPHITE

(sō'dī-i hŷ-pō-phōs'phis)

“It should contain not less than 98 percent. of pure Sodium Hypophosphite [$\text{PO} \cdot \text{H}_2\text{ONa} + \text{H}_2\text{O}$], and should be kept in well-stoppered bottles; caution should be observed in dispensing Sodium Hypophosphite, as explosion is liable to occur when it is triturated or heated with nitrates, chlorates, or other oxidizing agents.” *U. S.* “Sodium Hypophosphite, NaPH_2O_2 , is obtained by the interaction of sodium carbonate and calcium hypophosphite.” *Br.*

Natrium Hypophosphorosum, Hypophosphis Sodica; Hypophosphite of Soda; Hypophosphite de Soude, *Fr. Cod.*; Unterphosphorigsaures Natron, *G.*; Hipofosfito sodico, *Sp.*

Preparation.—Sodium hypophosphite is prepared by mixing solutions of calcium hypophosphite and monohydrated sodium carbonate, in the proportion of eight ounces of the former dissolved in five pints of water to six of the latter in two pints of water. Double decomposi-

¹ *London Paste.*—The formula used at the London Throat Hospital for preparing this caustic is as follows: Take of caustic soda and unslaked lime equal parts. Reduce to a fine powder in a warm mortar, and mix intimately. Keep in well-closed bottles, and when required for use take as much as is sufficient. It is recommended for destroying enlarged tonsils or the elongated uvula, where treatment with the “gullotine” or scissors is objected to. This preparation resembles the Vienna Paste, but is preferable in consequence of its being less liable to spread beyond the limits of application. Soda being used instead of potash, and water in place of alcohol, the operation is much less painful. (*N. R.*, Aug. 1878.)

tion takes place, with the formation of calcium carbonate and sodium hypophosphite, of which the latter is held in solution and the former is precipitated. After filtration to separate the calcium carbonate, the solution is evaporated to a pellicle, and then stirred constantly until the salt granulates, the heat being continued. If required quite pure, the granulated salt is dissolved in official alcohol, and the liquid, having been evaporated to a syrupy consistence, is set aside to crystallize.

Sometimes sodium hypophosphite explodes with violence during the evaporation of its solution. This was ascribed to the use of too high a temperature; but the same accident has occurred when the heat was applied by means of a water bath. (See *A. J. P.*, 1860, p. 87.) In a communication of Tuson to the *Chemical News* (No. 31, p. 46), it is stated that, though he had superintended the manufacture of large quantities of calcium and sodium hypophosphites, he had never witnessed anything like an explosion; but the heat employed in evaporation had never approached 100° C. (212° F.), and this is probably the true explanation. Caution, therefore, should be observed to evaporate at a low temperature.

Properties.—As described in the U. S. Pharm. (8th Rev.), sodium hypophosphite occurs in “small, colorless, transparent, rectangular plates of a pearly lustre, or a white, granular powder, odorless, and having a bitterish-sweet, saline taste. Very deliquescent on exposure to moist air. Soluble in about 1 part of water, and in about 25 parts of alcohol at 25° C. (77° F.); in 0.12 part of boiling water, and in 1 part of boiling alcohol; slightly soluble in absolute alcohol; insoluble in ether. When heated in a test-tube, the salt at first loses its water of crystallization, and at about 200° C. (392° F.) it is decomposed, evolving hydrogen and hydrogen phosphide which burns spontaneously with a bright yellow flame. Finally, there is left a residue of sodium pyrophosphate and metaphosphate, sometimes mingled with a little red phosphorus. To a non-luminous flame the salt imparts an intense yellow color. An aqueous solution of Sodium Hypophosphite is neutral or slightly alkaline to litmus paper. The diluted aqueous solution, slightly acidulated with diluted sulphuric acid, yields, with silver nitrate T.S., a white precipitate, which rapidly turns brown or black, owing to the separation of metallic silver. With copper sulphate T.S., on gentle heating, a reddish-brown precipitate is formed.

When the aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, is added, drop by drop, to an excess of mercuric chloride T.S., a white precipitate of mercurous chloride is formed. On further addition of the hypophosphite solution in excess, the precipitate becomes gray from reduction to metallic mercury. The aqueous solution (1 in 20) should not be colored red by the addition of a drop of phenolphthalein T.S., nor effervesce on the addi-

tion of an acid (absence of *caustic alkali* and *carbonate*). The aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If 5 Cc. of the aqueous solution of the salt (1 in 10) be measured into a beaker containing 3 Cc. of nitric acid, diluted with about 10 Cc. of water and evaporated to dryness on a water-bath, the residue should not respond to the Modified Gutzeit's Test for *arsenic* (see PART III, Test No. 17).” *U. S.*

Sodium hypophosphite is described in the British Pharmacopœia as “a white granular salt, having a bitter nauseous taste. It is deliquescent, soluble in its own weight of water and in 30 parts of alcohol (90 per cent.), but insoluble in ether. When heated in air it yields spontaneously inflammable hydrogen phosphide and hydrogen. It colors flame strongly yellow. It is rapidly attacked by oxidizing agents. Its solution yields with a warm solution of *copper sulphate* a red precipitate of cuprous hydride, which, on boiling, evolves hydrogen. 0.5 gramme boiled for ten minutes with 25 cubic centimetres of water and 1.15 grammes of *potassium permanganate*, and filtered, should afford a nearly colorless solution. It should yield no characteristic reaction with the tests for lead, copper, iron, aluminium, zinc, calcium, magnesium, potassium, ammonium, chlorides, or sulphates, only the slightest reactions with the tests for carbonates, and its solution should give little or no precipitate with *solution of lead acetate* (limit of phosphates and phosphites).” *Br.*

Hypophosphorous acid consists of one atom of phosphorus, two of oxygen, and three of hydrogen, of which, however, only one is replaceable by metal. It has a strong affinity for oxygen, and acts therefore as a powerful deoxidizing agent, as is shown by its reducing silver and mercury from their salts. The solubility of sodium hypophosphite is increased by the addition of hypophosphorous acid. As the soluble salts of mercury and silver are reduced by the hypophosphites, they are of course incompatible with sodium hypophosphite in prescriptions. With calcium hypophosphite, all the soluble sulphates and carbonates produce precipitates.

Uses.—The hypophosphites were first recommended by Churchill in the treatment of *phthisis* and subsequently by J. D. Brown in diseases attended with *loss of nerve power*, and in many of the complaints of infancy connected with the *scrofulous diathesis* and *defect in the osseous system*. (*B. M. S. J.*, lxxiii. 412, Dec. 21, 1865.) Their value is, however, problematical.

Dose, ten to twenty grains (0.65 to 1.3 Gm.), three times a day.

SODII IODIDUM. U. S., Br.

SODIUM IODIDE

(sò'di-ī ī-ōd'j-dūm)

NaI = 148.78

"It should contain not less than 98 percent of pure Sodium Iodide, and should be kept in well-stoppered bottles." *U. S.* "Sodium Iodide, NaI, may be prepared from iodine and sodium hydroxide by a process similar to that employed in making Potassium Bromide; the salt being crystallized at a temperature of not less than 68° F. (20° C.)." *Br.*

Iodure de Sodium, *Fr. Cod.*; Natrium Iodatum, *P. G.*; Natriumjodid, *Jodnatrium, G.*; Yoduro sodico, *Sp.*

Preparation.—This iodide may be prepared either by treating a solution of sodium hydroxide with iodine, or by double decomposition between ferrous iodide and sodium carbonate, precisely as potassium iodide is obtained by the corresponding processes for that salt. As only small quantities are likely to be wanted as a medicine, the latter process is preferable, being more easily conducted on a small scale. (See Procter's paper on the preparation of this iodide, in *A. J. P.*, July, 1854, p. 305.)

Properties.—It is a very soluble white salt, crystallizing in anhydrous cubes from a hot solution, and in oblique rhombic prisms, with two molecules of water, by spontaneous evaporation. It is officially described as in "colorless, cubical crystals, or a white, crystalline powder; odorless, and having a saline and slightly bitter taste. In moist air Sodium Iodide deliquesces and frequently undergoes decomposition, the salt assuming a brown tint. Soluble in about 0.5 part of water, and in about 3 parts of alcohol at 25° C. (77° F.); in 0.33 part of boiling water, and in 1.4 parts of boiling alcohol. When strongly heated the salt melts, and at a bright red heat it is slowly volatilized and partly decomposed. To a non-luminous flame it imparts an intense yellow color. An aqueous solution of Sodium Iodide is slightly alkaline to red litmus paper. If 1 Gm. of the salt be dissolved in water, and 0.1 Cc. of tenth-normal sulphuric acid V.S. be added, no red color should be produced by the addition of a drop of phenolphthalein T.S. even after heating (limit of *alkali*). If to 5 Cc. of the aqueous solution (1 in 20) 1 Cc. of chlorine water be added, iodine will be liberated and impart to the solution a light reddish-brown color. On agitating this mixture with a few drops of chloroform, the latter will acquire a violet color. A solution of 1 Gm. of the salt in 1 Cc. of water should yield no precipitate with 1 Cc. of sodium bitartrate T.S. (limit of *potassium*). The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If 0.5 Gm. of the

salt be dissolved in 10 Cc. of distilled water, which has been previously boiled and cooled in a small flask, the solution should not have a distinct yellow tint (absence of *free iodine*), nor should the solution acquire a yellow color within half a minute after the addition of 2 drops of diluted sulphuric acid (which should be free from sulphurous acid or nitrous acid) (limit of *iodate*). Ten Cc. of the aqueous solution of the salt (1 in 20), when acidulated with hydrochloric acid, should not be rendered turbid by the addition of 1 Cc. of potassium sulphate T.S. (absence of *barium*). If 5 Cc. of the aqueous solution be gently heated with 1 drop of ferrous sulphate T.S., 1 drop of ferric chloride T.S., and 0.5 Cc. of potassium hydroxide T.S., no blue color should appear after acidulating the mixture with hydrochloric acid (absence of *cyanide*). If to 1 Gm. of Sodium Iodide, contained in a test-tube of about 40 Cc. capacity, 5 Cc. of water, 5 Cc. of potassium hydroxide T.S., and about 0.2 Gm. of aluminum wire be added, and if in the upper portion of the test-tube a pledget of purified cotton be inserted, and over the mouth there be placed a piece of moistened red litmus paper, then if the tube be heated upon a water-bath for fifteen minutes, no blue coloration of the paper should be discernible (limit of *nitrates* and *nitrites*). If 0.2 Gm. of Sodium Iodide be dissolved in 2 Cc. of ammonia water, and 15 Cc. of tenth-normal silver nitrate V.S. be added, then after thoroughly agitating and filtering, the filtrate, upon supersaturating with nitric acid, should not become more than slightly turbid, nor should any darkening appear within ten minutes (limit of *chlorides* and *bromides*, and absence of *thiosulphate*). If 0.5 Gm. of the well-dried salt be dissolved in 10 Cc. of distilled water, and about 5 drops of potassium chromate T.S. be added, it should require not more than 34.6 Cc. nor less than 33 Cc. of tenth-normal silver nitrate V.S. to produce a permanent red color (corresponding to at least 98 percent. of pure Sodium Iodide)." *U. S.* "A dry white crystalline deliquescent powder, having a saline and somewhat bitter taste, readily soluble in less than its weight of water and in 3 parts of alcohol (90 per cent.). It affords the reactions characteristic of sodium and of iodides. Each gramme should not lose more than 0.05 gramme of water when dried at 248° F. (120° C.); and each gramme of this dried salt, when dissolved in water, should require for complete precipitation not less than 66.5 cubic centimetres of the *volumetric solution of silver nitrate*. It should yield no characteristic reaction with the tests for lead, copper, arsenium, iron, aluminium, calcium, magnesium, potassium, ammonium, bromates, cyanides, carbonates, or iodates, and only the slightest reactions with the tests for bromides, chlorides, or sulphates." *Br.*

Uses.—Sodium iodide has the same therapeutic effects and is used in the same diseases as potassium iodide. It is said to be better

borne than the latter iodide, although it contains about 8 per cent. more iodine than the potassium salt. In Italy it has been used with remarkable success in *constitutional syphilis*. At the suggestion of Gross, it was employed by John J. Black, at the Philadelphia Hospital, as a substitute for potassium iodide in the treatment of syphilitic affections, and seemed to be not less efficacious than that medicine, while producing none of its unpleasant effects. (*Am. J. M. S.*, July, 1865, p. 87.)

Dose, ten grains (0.65 Gm.), gradually increased to forty grains (2.6 Gm.), three times a day, dissolved in three fluidounces (90 Cc.) of water.

SODII NITRAS. U. S.

SODIUM NITRATE

(sō'dī-i nī'trās)

$\text{NaNO}_3 = 84.45$

"It should contain not less than 99 percent. of pure Sodium Nitrate $[\text{NO}_3\text{ONa}]$, and should be kept in well-stoppered bottles." *U. S.*

Nitrate of Soda, Cubic Nitre, Chile Saltpeter; Nitras (Azotas) Sodicus, Nitrum Cubicum; Azotate (Nitrates) de Soude, *Fr. Cod.*; Nitre cubique, Nitrate de Chili, *Fr.*; Natrium Nitricum, *P. G.*; Natriumnitrat, Chilesalpeter, *G.*; Nitratu di sodio, *It.*

This salt, called also *cubic nitre*, was first recognized as official in 1870. Sodium nitrate is imported from South America, where it is found naturally, especially in the desert of Atacama, forming beds of vast extent. The nitrate deposits have been found uniformly through a zone 250 geographical miles in length north to south, and two geographical miles in width east to west. It was estimated that the nitrate beds contained the enormous quantity of 99,031,525 tons, and it was stated that with the (1887) export duty the deposits would yield a revenue of £230,809,474. (*J. Soc. Chem. Ind.*, 1887, 229.) Attempts were made between 1820 and 1830 to export it to England and the United States; but the cargoes were unsalable. Soon afterwards, however, its value became known. The salt has been found also largely in Brazil, in the province of Bahia, near the river San Francisco. (*A. J. P.*, Nov. 1861, 502.) For an account of the sodium nitrate deposits of Chili, see *Potassii Nitrās*. The shipments of sodium nitrate from South American ports to all parts amounted in 1904 to 1,463,000 tons and in 1905 to 1,583,000 tons. The importations into the United States were, 1904, 297,864 tons valued at \$9,260,808; and in 1905, 282,692 tons valued at \$9,557,522. The crude salt is in saline lumps, rather soft and friable, and damp on the surface. Its varieties are classified, according to their color and state of aggregation, as *white compact*, *yellow compact*, *gray crystalline*, *white crystalline*.

"*Caliche*," as the crude mineral is called, contains from 48 to 75 per cent. of sodium nitrate,

from 20 to 40 per cent. of sodium chloride, and smaller amounts of sodium sulphate, calcium sulphate, potassium nitrate, and potassium and sodium iodate (from 0.059 to 0.175 per cent. of iodine). Occasionally calcium borate, associated with sodium borate, is found under the beds of the nitrate.

Properties.—Sodium nitrate, when pure, is in "colorless, transparent, rhombohedral crystals, odorless, and having a cooling saline, and slightly bitter taste. Hygroscopic in moist air. Soluble in about 1.1 parts of water, and in about 100 parts of alcohol at 25° C. (77° F.); in 0.6 part of boiling water, and in 40 parts of boiling alcohol. When heated to 312° C. (593.6° F.), the salt melts without decomposition. At a higher temperature it evolves oxygen, and is reduced to nitrite. When Sodium Nitrate is heated with charcoal, the mixture deflagrates. To a non-luminous flame it imparts an intense yellow color. Its aqueous solution is neutral to litmus paper. If the aqueous solution be mixed in a test-tube with a drop of diphenylamine T.S., and sulphuric acid be carefully poured in, so as to form a separate layer, a deep blue color will appear at the line of contact. The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If to 10 Cc. of the aqueous solution of the salt (1 in 20) 1 Cc. of chloroform be added, and then chlorine water which has been diluted with an equal volume of water be introduced, drop by drop, with agitation, the chloroform should remain free from any violet tint (absence of *iodide*)." *U. S.* Like potassium nitrate, it deflagrates when thrown on the fire, but it is distinguished by giving rise to an orange-yellow flame, and by the rhomboidal shape of its crystals, those of nitre being long six-sided prisms. It evolves ruddy fumes when warmed in a test-tube with sulphuric acid and copper wire.

Uses.—This salt has been praised as a remedy in *dysentery* (see 15th ed. *U. S. D.*), in the *dose* of from half an ounce to an ounce (15.5 to 31 Gm.) in the course of the day in dilute solution, but is at present very rarely, if ever, used in practical medicine.

Off. Prep.—Liquor Sodii Phosphatis Compositus, *U. S.*

SODII NITRIS. U. S., Br.

SODIUM NITRITE

(sō'dī-i nī'trīs)

$\text{NaNO}_2 = 68.57$

"It should contain not less than 90 percent. of pure Sodium Nitrite $[\text{NO}_2\text{ONa}]$, and should be kept in well-stoppered bottles." *U. S.* "A salt, NaNO_2 , obtained by fusing sodium nitrate with metallic lead." *Br.*

Nitrite of Sodium, Nitrite of Soda; Nitrite de Soude, *Fr.*; Salpetrigrasures Natron, *G.*

This salt was official in the U. S. Pharmacopœia of 1890 for the first time: it was introduced for the purpose of furnishing the nitrous radical to form ethyl nitrite in the preparation of spirit of nitrous ether. (See *Spiritus Ætheris Nitrosi*.)

Preparation.—According to M. A. Darbon it is made on a large scale as follows: Sodium nitrate is melted in large cast iron vessels, whereby hygroscopic water is removed and a part of the iodides and iodates, still present, are decomposed. At 310° C. the nitrate begins to fuse. It is heated to 400° to 420° C., and pure metallic lead in thin sheets is gradually added, the mass being constantly stirred, about 280 parts of lead being necessary for 100 parts of sodium nitrate used. The lead must be as free as possible from other metals and antimony particularly must be absent. When all the lead has been added, care having been exercised to prevent overheating, the stirring must be kept up for some time, and the melted mass is then, by means of a cast iron ladle, run in the form of thin threads into water with constant stirring.

In this process, besides the nitrite, about 1 per cent. of sodium hydroxide is produced, which in its turn dissolves a portion of lead, and has to be removed during the subsequent purification, either by nitric acid or by lead nitrate or sulphuric acid. The crude products are a solution containing the nitrite, undecomposed saltpetre, sodium hydroxide holding lead in solution, the soluble impurities of the sodium nitrate, such as sodium chloride, etc., and a residue consisting of lead oxide, a little metallic lead, and a certain proportion of lead peroxide. The solution strained from the residue, with the washings, is diluted to about 6° to 8° B., neutralized with nitric acid as long as a precipitate is formed, separated from this precipitate, concentrated to 42° to 45° B. while warm, and then left to crystallize—the crystals requiring possibly recrystallization. The pure crystals are separated by a centrifugal machine, washed, dried and packed in cylinders of double thickness of parchment paper. (*Chem. News*, Sept. 22, 1899, 146.)

Properties.—It is officially described as in "white, opaque, fused masses, or pencils, or colorless, transparent, hexagonal crystals; odorless, and having a mild, saline taste. When exposed to the air, the salt deliquesces and is gradually oxidized to sodium nitrate, and becomes unfit for use. Soluble in about 1.4 parts of water at 25° C. (77° F.), and very soluble in boiling water; slightly soluble in alcohol. When heated, the salt melts, and at a red heat it is decomposed, yielding oxygen, nitrogen dioxide, and sodium oxide. To a non-luminous flame it imparts an intense yellow color. An aqueous solution of Sodium Nitrite should be colorless and give a slightly alkaline reaction with red litmus paper. If the aqueous solution of the salt be mixed with some potassium iodide T.S., and a few drops of

an acid added, iodine will be liberated, and nitrogen dioxide gas will escape with effervescence. If 1 Gm. of the salt be dissolved in 20 Cc. of diluted hydrochloric acid, and heated sufficiently to expel the gases, the resulting solution after restoring it to its original volume should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If to 30 Cc. of tenth-normal potassium permanganate V.S., diluted with about 150 Cc. of distilled water, 5 Cc. of sulphuric acid and 10 Cc. of a solution of 1 Gm. of Sodium Nitrite in sufficient distilled water to make 100 Cc. be successively added, the liquid brought to a temperature of 40° C. (104° F.) and allowed to stand for five minutes, not more than 3.75 Cc. of tenth-normal oxalic acid V.S. should be required to decolorize the solution (each Cc. of tenth-normal potassium permanganate consumed corresponding to 0.0034285 Gm. of pure Sodium Nitrite)." U. S. The British Pharmacopœia defines it as "a white deliquescent crystalline powder, very soluble in water. The solution is neutral or slightly alkaline, and affords reactions characteristic of sodium salts and of nitrites. 0.1 gramme dissolved in water, introduced into a brine-charged nitrometer, and tested with *potassium iodide* and *diluted sulphuric acid*, should liberate at the ordinary temperature (60° F. or 15.5° C.) and pressure (30 inches or 760 millimetres of mercury) not less than 32.5 cubic centimetres of nitric oxide, corresponding to not less than 95 per cent. of sodium nitrite, the gas being almost completely absorbed by strong solution of *ferrous sulphate*. The aqueous solution of the salt should not give more than the slightest traces of a precipitate on the addition of *diluted sulphuric acid* (absence of lead)." Br.

Uses.—Sodium nitrite acts upon the animal organism precisely as do the other nitrites, being more slowly absorbed, however, and much less rapidly eliminated. Its influence is, therefore, more slowly manifested and much more permanent than is that of amyl nitrite or nitroglycerin. Ten grains are sufficient to cause flushing of the face and markedly increased heart action; indeed, five grains are said to have produced serious symptoms. (*L. L.*, ii. 1883.) It is evident that, although twenty grains of the commercial sodium nitrite have been given without serious effect, the commencing *dose* of the pure article should not exceed three grains (2.0 Gm.).

SODII PHENOLSULPHONAS.

U. S. (Br.)

SODIUM PHENOLSULPHONATE [*Sodii Sulphocarbolas*, Pharm. 1890, Sodium Sulphocarbolate]

(sô'di-i phê-nôl-sul'pho-nâs)

"It should contain not less than 99 percent. of pure Sodium Paraphenolsulphonate [*CsH*]

(OH)SO₃Na 1:4 + 2H₂O], and should be kept in well-stoppered bottles." *U. S.* "Sodium Sulphocarbonate, or sodium phenol-para-sulphonate, C₆H₄OH.SO₂ONa.2H₂O, may be obtained by dissolving phenol in excess of sulphuric acid, and converting the phenolsulphonic acid so obtained into a sodium salt." *Br.*

Sodii Sulphocarbolas. *Br., U. S.* 1890; Sodium paraphenolsulphonate; Sodium Sulphophenate; Sulphophénate de Soude, *Fr.*; Phenolsulfosaures Natrium, Phenylschwefelsaures Natron, *G.*

Sodium phenolsulphonate may be made by mixing equal parts of pure phenol and strong sulphuric acid, whereby *paraphenol sulphonic acid* (sulphocarbolic acid), C₆H₄(HSO₃)OH, is produced. The mixed liquids must be subjected to a temperature of 55° C. (131° F.) for several days, and then twenty parts of water should be added. Two parts of barium carbonate are added to the liquid, a little at a time, carefully graduating the quantity until effervescence ceases. The liquid is now allowed to stand to permit the precipitation of barium sulphate, and of any carbonate which might be present, and the liquor filtered. The solution of *barium phenolsulphonate* is decomposed by adding sodium carbonate until precipitation ceases, when the liquid is filtered from the barium carbonate, and the sodium phenolsulphonate may be obtained by evaporating the filtrate and crystallizing.

Properties.—The *U. S.* Pharmacopœia describes this salt as in "colorless, transparent, rhombic prisms; odorless, and having a cooling, saline, bitter taste. Somewhat efflorescent in dry air. Soluble in 4.8 parts of water, and in about 130 parts of alcohol at 25° C. (77° F.); in 0.7 part of boiling water, and in 10 parts of boiling alcohol. When heated a little above 100° C. (212° F.), the salt loses all of its water of crystallization (15.5 percent.), and becomes white. At a higher temperature it chars, emits inflammable vapors having the odor of phenol, and finally leaves a residue of sodium sulphate amounting to 30.6 percent. of the original weight. To a non-luminous flame it imparts an intense yellow color. An aqueous solution of Sodium Phenolsulphonate is neutral to litmus paper. A diluted solution of the salt (1 in 100) is rendered pale violet by ferric chloride T.S., but remains clear; barium chloride T.S. leaves the solution clear, but if a portion of the salt be ignited, and the residue dissolved in water, the same reagent will produce in the solution a copious, white precipitate. The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121)." *U. S.* "Soluble in 6 parts of water, and in 150 parts of alcohol (90 per cent.), the solutions being without action on litmus. On ignition it gives off phenol, and leaves a residue of sodium sulphate. It imparts an intense yellow color to flame. The dilute aqueous solution is rendered violet by *test-solution of*

ferric chloride, does not give a yellowish-brown precipitate with *solution of uranium nitrate* (distinction from salicylate), and should not at once be rendered turbid by *solution of barium chloride* (absence of sulphates)." *Br.*

Uses.—The sulphocarbonates, or as now called, the phenolsulphonates, have been introduced into medicine with the idea that they would unite the properties of sulphuric acid and phenol. It is, however, probable that they are inert; future investigations can alone give us positive information.

Dose, five to ten grains (0.32 to 0.65 Gm.).

SODII PHOSPHAS. U. S., Br.

SODIUM PHOSPHATE [Sodium Orthophosphate]

(sô'di-i phôs'phäs)

"It should contain, in an uneffloresced condition, not less than 99 percent. of pure Disodium-ortho-phosphate [PO.(OH)(ONa)₂ + 12H₂O], and should be kept in well-stoppered bottles, in a cool place." *U. S.* "This salt, disodium hydrogen phosphate, Na₂HPO₄.12H₂O, may be obtained by the interaction of sodium carbonate and the solution of acid calcium phosphate produced on mixing bone-ash and sulphuric acid." *Br.*

Medicinal Tribasic Sodium Phosphate, Phosphate of Soda; Disodium Hydrogen Phosphate; Phosphas Sodicus (Natrius), Sal Mirabile Perlatum; Phosphate de Soude, *Fr. Cod.*; Natrium Phosphoricum, *P. G.*; Natriumphosphat, Phosphorsaures Natron, *G.*; Fosfato bisodico, *It.*; Fosfato sodico, *Sp.*

A process for this salt is no longer official; for that of the *U. S. P.* 1870, see foot-note.¹

The incombustible part of bones is obtained by burning them to whiteness, and consists of neutral calcium phosphate, called bone phosphate, associated with some calcium carbonate, etc. (See *Os Ustum.*) When this is mixed with sulphuric acid, the calcium carbonate is entirely decomposed, giving rise to effervescence. The calcium phosphate undergoes partial decom-

¹ *Sodii Phosphas.*—"Take of Bone, calcined to whiteness and in fine powder, one hundred and twenty troyounces; Sulphuric Acid seventy-two troyounces; Carbonate of Sodium, Water, each, a sufficient quantity. Mix the powder with the Sulphuric Acid in an earthen vessel; then add eight pints of Water, and, having stirred the mixture thoroughly, digest for three days, occasionally adding a little Water to replace that which is lost by evaporation, and frequently stirring the mixture. At the expiration of that time, pour in eight pints of boiling Water, and strain through muslin, gradually adding more boiling Water until the liquid passes nearly tasteless. Set by the strained liquor that the dregs may subside, and, having poured off the clear solution, boil it down to eight pints. To the concentrated liquid, poured off from the newly-formed dregs and heated in an iron vessel, add by degrees Carbonate of Sodium, previously dissolved in hot Water, until effervescence ceases, and the phosphoric acid is completely saturated; then filter the liquid, and set it aside to crystallize. Having removed the crystals, add, if necessary, a small quantity of Carbonate of Sodium to the liquid, so as to render it slightly alkaline; then alternately evaporate and crystallize, so long as crystals are produced. Lastly, keep the crystals in a well-stopped bottle." *U. S.* 1870.

position; the greater part of the lime, being detached, precipitates as calcium sulphate, while the phosphoric acid, set free, combines with the undecomposed portion of the phosphate, and remains in solution as an acid calcium phosphate, holding dissolved a small portion of the calcium sulphate. In order to separate the acid phosphate from the precipitated mass of calcium sulphate, boiling water is added to the mixture, the whole is strained, and the sulphate washed as long as acid phosphate is removed, which is known by the water passing through in an acid state. The different liquids which have passed the strainer, consisting of the solution of acid calcium phosphate, are mixed and allowed to stand, and by cooling a portion of calcium sulphate is deposited, which is separated by subsidence and decantation as before. The acid calcium phosphate solution, being heated, is now saturated by means of a hot solution of sodium carbonate. The carbon dioxide is liberated with effervescence, and the alkali, combining with the excess of acid of the acid phosphate, produces a sodium phosphate, while the acid calcium phosphate, by the loss of its excess of acid, becomes the neutral phosphate and precipitates. The calcium phosphate is separated by a new filtration, and the filtered liquor, which is a solution of sodium phosphate, is evaporated so as to crystallize.

In the U. S. process of 1870 the calcined bone is to the acid as 10 to 6; in the Br. process of 1867 as 10 to 6½ nearly. The proportion recommended by Berzelius is as 10 to 6.66. The acid, in the former official process, was added to the calcined bone in the concentrated state, and afterwards diluted with more or less water. In the process given by Berzelius it is first diluted with twelve times its weight of water. All the writers state that sodium phosphate crystallizes more readily by allowing its solution to be slightly alkaline, and a remarkable fact is, that a neutral solution, when it crystallizes, leaves a supernatant liquid which is slightly acid and uncrystallizable. Hence it is necessary, after getting each successive crop of crystals, to render the mother water slightly alkaline, before it will furnish an additional quantity.

Funcke, a German chemist, has given the following cheap and expeditious method for obtaining sodium phosphate. To the powdered calcined bone, diffused in water, sufficient diluted sulphuric acid is added to decompose all the calcium carbonate which it contains. When the effervescence ceases, the matter is treated with nitric acid, which dissolves the calcium phosphate and leaves the sulphate. The nitric solution of the phosphate is then treated with sodium sulphate, equal in quantity to the bone employed, and after the reaction is completed, the nitric acid is recovered by distillation. In consequence of a double decomposition, calcium

sulphate and sodium phosphate are formed, the latter of which is separated by water, and crystallized in the usual manner.

Properties.—The medicinal sodium phosphate, according to the U. S. Pharmacopœia (8th Rev.), is in "large, colorless, monoclinic prisms, or a granular, crystalline salt; odorless, and having a cooling, saline taste. The crystals effloresce in the air, and gradually lose 5 molecules of their water of crystallization (25.1 percent.). Soluble in about 5.5 parts of water at 25° C. (77° F.); insoluble in alcohol. When heated to about 40° C. (104° F.), the salt fuses, yielding a colorless liquid. At 100° C. (212° F.) it loses all its water of crystallization (60.3 percent.), and at a red heat is converted into sodium pyrophosphate. It imparts to a non-luminous flame an intense yellow color. An aqueous solution of Sodium Phosphate is slightly alkaline to red litmus and phenolphthalein paper. An aqueous solution of the salt (1 in 20) yields a white, crystalline precipitate with magnesia mixture T.S. With silver nitrate T.S. an aqueous solution yields a yellow precipitate, soluble in ammonia water and in nitric acid. If 0.5 Cc. of the aqueous solution (1 in 20) be mixed with 1 Cc. of ammonium molybdate T.S., the mixture will at once assume a yellow color, and after being gently heated a few minutes will yield a yellow precipitate. No residue should be left on dissolving the salt in water (absence of calcium, etc.). The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for heavy metals (see PART III, Test No. 121). No effervescence should occur on the addition of hydrochloric or nitric acid to a solution of the salt (absence of carbonate). Five Cc. of the aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzeit's Test for arsenic (see PART III, Test No. 17)." *U. S.* "In transparent colorless rhombic prisms, terminated by four converging planes, efflorescent, having an alkaline reaction and a saline taste. It is soluble in 6 parts of cold water. It affords the reactions characteristic of sodium and of phosphates. Heated to dull redness, it loses 62.84 per cent. of its weight." *Br.*

Before the blowpipe, sodium phosphate at first undergoes the aqueous fusion, and afterwards, at a red heat, melts into a globule of limpid glass, which becomes opaque on cooling. It is liable to adulteration, sometimes containing sodium carbonate, from this salt having been added in excess in its preparation, in which case it will effervesce with acids. If it contain sodium sulphate, or any other soluble sulphate, the precipitate caused by barium chloride will be a mixture of barium sulphate and phosphate, and will not be totally soluble in nitric acid. A. B. Lyons found a specimen which consisted almost entirely of sodium sulphate. (*A. J. P.*, 1875, 371; see also *N. R.*, April, 1877.) Barium chloride will detect sodium carbonate also, by producing a precipitate

of barium carbonate, soluble with effervescence in nitric acid. If a chloride be present, the yellow precipitate caused by silver nitrate will be a mixed one of silver chloride and phosphate, not entirely soluble in the same acid. The salt is incompatible with soluble salts of lime, with which it gives a precipitate of calcium phosphate, and with neutral metallic solutions. It is found in several of the animal secretions, particularly the urine. For an elaborate article upon the methods of determining the percentage of phosphates present in a substance, see *Chem. News*, Oct. 1874, 200. Samples of sodium phosphate have been found in commerce contaminated with arsenic in dangerous quantities. The official test to detect arsenic should always be applied to sodium phosphate. (*C. D.*, June 30, 1900, 1073; *Am. Drug.*, Aug. 27, 1900, 103.)

The medicinal sodium phosphate is one of the three sodium salts of tribasic phosphoric acid, H_3PO_4 . In this salt two of the three replaceable hydrogen atoms have been replaced by sodium, so that its formula is $\text{HN}\text{a}_2\text{PO}_4$, which then crystallizes out with 12 molecules of water. Its complete formula is then $\text{HN}\text{a}_2\text{PO}_4 \cdot 12\text{H}_2\text{O}$. When gently heated, it loses its water of crystallization (see *Sodii Phosphas Exsiccatus*) and at a red heat the salt is converted into sodium pyrophosphate, $\text{Na}_2\text{P}_2\text{O}_7$. (See *Sodii Pyrophosphas*.)

Uses.—Sodium phosphate was introduced into practice about the year 1800 by Pearson of London. In doses of from one to two ounces (31 to 62 Gm.) it is a mild purgative, and, from its pure saline taste, is well adapted to the cases of children, and of persons of delicate stomach. In smaller doses it has been considerably used, generally in connection with other phosphates, to meet any real or supposed deficiency of phosphates in the system, and for this purpose it is well adapted by its ready solubility. As was first observed by Wm. Stephenson of Edinburgh, it has, especially in children, an extraordinary influence upon the hepatic secretion. In infantile cases, with *white or green stools*, with *diarrhœa*, and sometimes with *jaundice*, these evidences of deficient or disordered bile often quickly yield to small doses of sodium phosphate, the passages assuming their healthy yellow color, and the attendant disease generally disappearing. These statements of Stephenson are confirmed by the experience of H. C. Wood, at least in regard to children.

Dose, of sodium phosphate, from three or four to ten grains (0.20 or 0.26 to 0.65 Gm.) for children, according to their age, best administered with their food, especially milk; it may be repeated whenever there is occasion to give food. To adults from twenty to forty grains (1.3 to 2.6 Gm.) may be given, dissolved in water, after meals.

SODII PHOSPHAS EFFERVESCENS.

U. S., Br.

EFFERVESCENT SODIUM PHOSPHATE

(sô'di-i phôs'phās êf-fer-vēs'cens)

Sodii Phosphas Effervescens; *Effervescent Phosphate of Soda*; *Natrium Phosphoricum Effervescens*; *Phosphate de Soude effervescent, Fr.*; *Brausendes Natriumphosphat, G.*

* "*Exsiccated Sodium Phosphate, in fine powder, two hundred grammes [or 7 ounces av., 24 grains]; Sodium Bicarbonate, dried and powdered, four hundred and seventy-seven grammes [or 16 ounces av., 361 grains]; Tartaric Acid, dried and powdered, two hundred and fifty-two grammes [or 8 ounces av., 389 grains]; Citric Acid, uneffloresced crystals, one hundred and sixty-two grammes [or 5 ounces av., 313 grains], to make about one thousand grammes [or 35 ounces av., 120 grains]. Powder the Citric Acid and mix it intimately with the Exsiccated Sodium Phosphate and Tartaric Acid, then thoroughly incorporate the Sodium Bicarbonate. Place the mixed powders on a plate of glass or in a suitable dish, in an oven heated to between 93° and 104° C. (199.4° and 219.2° F.). When the mixture has acquired a moist consistence, by the aid of careful manipulation with a wooden spatula, rub it through a No. 6 tinned-iron sieve, and dry the granules at a temperature not exceeding 54° C. (129.2° F.). Keep the product in well-stoppered bottles."* *U. S.*

"Sodium Phosphate, in crystals, 50 ounces (Imperial) or 500 grammes; Sodium Bicarbonate, in powder, 50 ounces (Imp.) or 500 grammes; Tartaric Acid, in powder, 27 ounces (Imp.) or 270 grammes; Citric Acid, in powder, 18 ounces (Imp.) or 180 grammes. Dry the Sodium Phosphate until it has lost 60 per cent. of its weight; powder the product and mix it with the other ingredients. Place the whole in a dish or pan of suitable form heated to between 200° and 220° F. (93.3° and 104.4° C.). When the mixture, by aid of careful manipulation, has assumed a granular character, separate it into granules of uniform and convenient size by means of suitable sieves. Dry the granules at a temperature not exceeding 130° F. (54.4° C.). The product should weigh about 100 ounces (Imp.) or 1000 grammes." *Br.*

This salt, introduced in the *Br. Add.* 1885, and into the *U. S. P.* (8th Rev.), affords a pleasant means of giving sodium phosphate.

Dose, one-fourth to one-half ounce (7.7 to 15.5 Gm.).

SODII PHOSPHAS EXSICCATUS. U. S.

EXSICCATED SODIUM PHOSPHATE

(sô'di-i phôs'phās êx-sic-cā'tūs)

"It should contain not less than 99 percent. of pure anhydrous Sodium Phosphate [$\text{PO}(\text{OH})(\text{ONa})_2$], and should be kept in well-stoppered bottles." *U. S.*

"Sodium Phosphate, a convenient quantity. Allow the crystals to effloresce for several days in warm air, at a temperature of from 25° to 30° C. (77° to 86° F.), then continue the drying in an oven; raise the temperature very gradually until 100° C. (212° F.) has been reached, and maintain this temperature until the salt ceases to lose weight. Powder and sift the residue, and preserve it in well-stoppered bottles." *U. S.* This salt was introduced in this form for use in making effervescent sodium phosphate. Forty parts of exsiccated sodium phosphate represent about 100 parts of crystallized sodium phosphate (see *Sodii Phosphas*).

Properties.—It is officially described as "a white powder which absorbs moisture readily, and conforms to the reactions and tests given under *Sodii Phosphas*." *U. S.*

Uses.—Exsiccated Sodium Phosphate is not used medicinally, but it is suited for administering sodium phosphate in capsules, or in pilular form, because the pills would be smaller than those made from the crystallized salt.

Dose, three to fifteen grains (0.2 to 1.0 Gm.).

Off. Prep.—*Sodii Phosphas Effervescens, U. S.*

SODII PYROPHOSPHAS. U. S.

SODIUM PYROPHOSPHATE

(sō'di-i pŷ-ro-phōs'phās)

"It should contain, in an uneffloresced condition, not less than 99 per cent. of pure Sodium Pyrophosphate [(PO)₂O.(ONa)₄ + 10H₂O], and should be kept in well-stoppered bottles." *U. S.*

Natrium Pyrophosphoricum; Pyrophosphate de Soude, *Fr. Cod.*; Natriumpyrophosphat, *G.*; Pirofosfato sodico, *Sp.*

This official salt is prepared by heating sodium phosphate in a suitable vessel to redness. When sodium phosphate is subjected to a temperature of 44° C. (111.2° F.), it melts in its water of crystallization; if the heat be increased to 100° C. (212° F.), all the water will be expelled, and but 40 per cent. of the original weight remain; at 300° C. (572° F.) it is converted into the tetrabasic phosphate or pyrophosphate. By dissolving this residue in water, filtering and crystallizing, the salt may be obtained.¹

Properties.—It is officially described as in "colorless, transparent, monoclinic prisms, or a crystalline powder; odorless, and having a cooling, saline, and feebly alkaline taste; slightly efflorescent in warm air. Soluble in about 11.5 parts of water at 25° C. (77° F.), and in 1.1 parts of boiling water; insoluble in alcohol. When heated to 100° C. (212° F.), the salt loses its water of crystallization (40.35 per-

cent.) without previous fusion. At a higher temperature it fuses, forming a transparent liquid, which, on cooling, solidifies to a crystalline mass. To a non-luminous flame it imparts an intense yellow color. An aqueous solution is feebly alkaline to red litmus and to phenolphthalein paper. An aqueous solution of the salt (1 in 20) yields with magnesia mixture a white precipitate; with silver nitrate T.S. it yields a white precipitate (distinction from orthophosphate); this precipitate is soluble in ammonia water and also in nitric acid without effervescence (absence of carbonate). With an excess of ammonium molybdate T.S. no precipitate is formed within fifteen or twenty minutes, even when a gentle heat is applied (distinction from orthophosphate). The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). Five cubic centimeters of the aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzeit's Test for *arsenic* (see PART III, Test No. 17)." *U. S.*

Uses.—The action of this salt upon the human economy is probably that of the phosphate.

SODII SALICYLAS. U. S., Br.

SODIUM SALICYLATE

(sō'di-i sāl-i-cy'lās)

"It should contain not less than 99.5 per cent. of pure Sodium Salicylate [C₆H₄(OH)COONa], and should be kept in well-stoppered bottles, protected from heat and light." *U. S.* "Sodium Salicylate, (C₆H₄.OH.COONa)₂.H₂O, may be obtained by the interaction of salicylic acid and sodium carbonate or sodium hydroxide." *Br.*

Salicylate of Soda; Salicylate de Soude, *Fr. Cod.*; Natrium salicylicum, *P. G.*; Natriumsalicylat, *G.*; Salicciato di sodio, *It.*; Salicciato sodico, *Sp.*

This salt was introduced into the U. S. Pharmacopœia at the revision of 1880. It is prepared by mixing 100 parts of pure salicylic acid with sufficient water to form a paste, and then with 104 parts of pure crystallized sodium carbonate (*U. S. P.* 1890) (uneffloresced) in a glass or porcelain vessel; carbon dioxide will be evolved, and sodium salicylate will remain in solution. The liquid may be strained through thoroughly washed muslin, if necessary, and heated in an evaporating dish until the carbon dioxide is expelled. If alkaline to litmus paper, enough salicylic acid must be added to be slightly in excess, and the solution is then evaporated at a low heat to dryness. If the acid be not in excess, the salt will not be white, but gray or lead-colored. Hager (*N. R.*, Nov. 1879) furnished the table on page 1155, whereby, in the absence of the crystallized sodium salicylate, the salt may be prepared in *solution*, by using the given proportions, in parts by weight, of

¹ This salt has been highly recommended for removing ink stains from colored cotton fabrics. It is said to remove the stains slowly without affecting the other colors.

salicylic acid and sodium bicarbonate. These figures differ somewhat from those given in the official saturation table, as given in the U. S. P. (8th Rev.).

Properties.—Pure sodium salicylate is a “white, microcrystalline powder or scales, or an amorphous, colorless powder, or having not more than a faint pink tinge; odorless, and having a sweetish, saline taste. Soluble in 0.8 part of water, and in 5.5 parts of alcohol at 25° C. (77° F.); very soluble in boiling water or alcohol; also soluble in glycerin. When heated, the salt is decomposed, giving off inflammable vapors and an odor of phenol, and finally leaves a residue of sodium carbonate. To a non-luminous flame it imparts an intense yellow color. An aqueous solution of Sodium Salicylate, when freshly made, should be colorless, and should slightly redden blue litmus paper. Ferric chloride T.S., added to an excess of a concentrated solution of the salt, produces a violet precipitate; but when added to a dilute solution (1 in 100), it produces a deep violet-blue color. If copper sulphate T.S. be added to the aqueous solution (1 in 20), a green color is produced. On adding to about 0.2 Gm. of the salt, in a test-tube, about 1 Cc. of concentrated sulphuric acid, and then, cautiously, drop by drop, about 1 Cc. of methyl alcohol, and heating the mixture to boiling, methyl salicylate will be evolved, recognizable by its odor. Diluted hydrochloric or sulphuric acid produces in a concentrated aqueous solution of the salt a voluminous, white precipitate, which, after being separated by filtration, and washed, should conform to the reactions and tests given under *Acidum Salicylicum*. If to an aqueous solution of the salt (1 in 20), 3 drops of iodine T.S. and a slight excess of hydrochloric acid be added, the filtrate from this mixture should not yield a precipitate upon the addition of barium chloride T.S. (absence of *sulphites*). If the aqueous solution of the salt (1 in 20) be acidulated with hydrochloric acid and filtered, the filtrate should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If 1 Gm. of dry Sodium Salicylate be thoroughly ignited at a red heat, and the residue extracted with boiling distilled water until the washings cease to react with methyl-orange T.S., the mixed filtrate and

washings should require for complete neutralization not less than 12.5 (12.52) Cc. of half-normal sulphuric acid V.S., methyl-orange T.S. being used as indicator.” *U. S.* “When heated to redness, the salt evolves inflammable vapors, and a white residue remains which effervesces with acids, and imparts an intense yellow color to flame. *Test-solution of ferric chloride* colors a concentrated solution reddish-brown, and a dilute solution violet. A solution containing not less than 1 per cent. affords a yellowish-brown precipitate with *solution of uranium nitrate* (distinction from carbolates and sulphocarbolates). 50 to 100 grammes kept in a closed vessel for several days should not evolve the faintest odor of phenol. If the aqueous solution be acidulated with *nitric acid* and the precipitate be dissolved by a little *alcohol* (90 per cent.), the mixture affords not more than the slightest reactions with the tests for sulphates or for chlorides. It dissolves without coloration or effervescence in cold *sulphuric acid* (absence of organic impurities and of carbonates).” *Br.* Sodium salicylate is incompatible with antipyrine, forming, when mixed in powder, a liquid mixture.

Uses.—The action of sodium salicylate upon the economy, and its therapeutic use, are precisely those of salicylic acid, except that the salt is not locally irritating, and, being soluble, is more rapidly absorbed. When salicylic acid is administered, it is probably converted into sodium salicylate as fast as it is taken into the blood. One drachm of the salt contains about fifty grains of the acid.

Dose, from ten to thirty grains (0.6 to 2.0 Gm.).

SODII SULPHAS. U. S., Br.

SODIUM SULPHATE [Glauber's Salt]

(sŏ'di-i sŭl'phās)

“It should contain, in an uneffloresced condition, not less than 99 percent. of pure Sodium Sulphate $[\text{SO}_2(\text{ONa})_2 + 10\text{H}_2\text{O}]$, and should be kept in well-closed vessels, in a cool place.”

Sulphate of Soda: Sulfas Sodicus (Natrius), Sal mirabile Glauberi; Vitriolated Soda, Glauber's Salt; Sulfate de Soude purifié, *Fr. Cod.*; Sel de Glauber, *Fr.*; Natrium Sulfuricum, *P. G.*; Natriumsulfat, *Schwefelsaures Natron*, *Glaubersalz*, *G.*; Solfato di Sodio, *It.*; Sulfato Sodico, Sal admirable de Glaubero, *Sp.*

Sodium sulphate, in small quantities, is extensively diffused in nature, and is obtained artificially in several chemical operations. It exists in solution in many mineral springs, among which may be mentioned those of Cheltenham and Carlsbad, and it is found combined with calcium sulphate constituting a distinct mineral. Many ponds containing this salt are found in the country between Santa Fé and the head waters of the Arkansas, and on the route to the Rocky Mountains. See reference to natural sodium carbonate and sulphate as found in Wyoming. (*Sodii Carbonas*, p. 1139.) A large deposit of Glauber's salt has been found in the Caucasus, not far from Tiflis. It is about ten feet below the surface, and was penetrated five feet, and probably extended much deeper. There are, besides, in the same region, various lakelets, containing the same salt in solution. (*N. R.*, Oct. 1872, 151.) As an artificial product, sodium sulphate is formed in the processes for obtaining hydrochloric acid and chlorine, and in the preparation of ammonium chloride from ammonium sulphate and common salt. It may also be procured from sea water, in which its ingredients are present.

Immense quantities of sodium sulphate are made by decomposing common salt by sulphuric acid, in the manufacture of soda-ash and sodium carbonate (see *Sodii Carbonas*), and, so far from the generated hydrochloric acid being a product of much value, its absorption in a convenient way, so as to avoid the nuisance of its escape into the atmosphere in a gaseous state, is an object of importance to the manufacturer. (See *Acidum Hydrochloricum*.) Thomas, Dellisse, and Boucard have proposed a process for preparing sodium sulphate, by double decomposition between sodium chloride and ferrous sulphate. This process avoids the production of hydrochloric acid vapors, and is said to furnish a cheap salt.

The residue of the process for obtaining chlorine by the action of sulphuric acid and manganese dioxide on common salt is a mixture of sodium sulphate and manganous sulphate. Large quantities of this residue are formed in manufacturing chlorinated lime (bleaching powder), and the sodium sulphate in it, roughly purified, supplies a part of the salt consumed in making soda-ash and sodium carbonate.

The process for obtaining ammonium chloride from ammonium sulphate and common salt forms another source of sodium sulphate. By double decomposition, sodium sulphate and ammonium chloride are formed, and by ex-

posing the mixed salts to heat, the ammonium chloride sublimes, and the sodium sulphate remains behind. (See *Ammonii Chloridum*.)

Properties.—Sodium sulphate is in "large, colorless, transparent, monoclinic prisms, or granular crystals; odorless, and having a bitter, saline taste. The salt effloresces rapidly in the air, and finally loses all of its water of crystallization. Soluble in 2.8 parts of water at 15° C. (59° F.), in 0.25 part at 34° C. (93.2° F.), and in 0.47 part at 100° C. (212° F.); insoluble in alcohol; soluble in glycerin. When heated to 33° C. (91.4° F.), the salt fuses, and, on continuing the heat to 100° C. (212° F.), it loses all of its water of crystallization (55.9 percent.). At a red heat the anhydrous salt fuses without decomposition. To a non-luminous flame it imparts an intense yellow color. Its aqueous solution is neutral to litmus paper. An aqueous solution of Sodium Sulphate (1 in 20) yields, with barium chloride T.S., a white precipitate insoluble in hydrochloric acid. The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for heavy metals (see PART III, Test No. 121). Five Cc. of the aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzeit's Test for arsenic (see PART III, Test No. 17)." *U. S.* "Soluble in less than half its weight of water at temperatures from 77° to 86° F. (25° to 30° C.). Heated to boiling this solution deposits crystals of the anhydrous salt. Insoluble in alcohol (90 per cent.). Exposed to heat in a porcelain crucible it loses 55.9 per cent. of water. It affords the reactions characteristic of sodium and of sulphates. Each gramme dissolved in water and acidulated with hydrochloric acid gives, by the addition of solution of barium chloride, a white precipitate, which, when it has been washed and dried, should weigh 0.725 gramme. It should yield no characteristic reaction with the tests for lead, iron, aluminium, calcium, magnesium, potassium, ammonium, or carbonates, and only the slightest reactions with the tests for chlorides." *Br.* When recently prepared it is beautifully transparent; but on exposure to the air it effloresces, and the crystals become covered with an opaque white powder. After long exposure it undergoes complete efflorescence, and falls into powder with loss of more than half its weight. A supersaturated solution of sodium sulphate will remain without crystallizing at ordinary temperatures, even though containing several times the weight of the salt that will be dissolved at the same degree of heat. But the solution instantly forms into a crystalline mass upon adding to it a fragment of the same salt crystallized, or other substances that have been exposed to the air, or upon abruptly placing it in contact with the air.

When crystallized sodium sulphate is subjected to heat it dissolves in its water of crystallization, then dries, and afterwards by

the application of a red heat melts with the loss of $55\frac{1}{2}$ per cent. of its weight. Coppet has ascertained that there are two varieties of the anhydrous sulphate,—one in which the salt is deprived of its water at ordinary temperature, the other in which the desiccation is effected at a heat above that of 33° C. (91.4° F.). The two differ in their relation to the crystallization of the salt, the former causing immediate crystallization when thrown into a supersaturated solution, the second not. (*J. P. C.*, 1874, 36.) Occasionally it contains an excess of acid or alkali, which may be discovered by litmus or turmeric paper. Common salt may be detected by silver nitrate; a salt of iron by potassium ferrocyanide. This salt is not subject to adulteration. It is incompatible with potassium carbonate, calcium chloride, the salts of barium, lead acetate and subacetate, and with silver nitrate if the solutions are strong. It consists of two atoms of sodium combined with the group SO_4 characteristic of sulphates, and crystallizes with ten molecules of water, $\text{Na}_2\text{SO}_4 + 10\text{H}_2\text{O}$.

Uses.—Sodium sulphate in doses of from half an ounce to an ounce (15.5 to 31 Gm.) is an efficient hydragogue cathartic; in smaller doses, an aperient and diuretic. When in an effloresced state, the dose must be reduced one-half, on account of its having lost about one-half of its weight of water. Sodium sulphate is much less used than formerly, having been almost entirely superseded by magnesium sulphate, which is less disagreeable to take and milder in its action. Its nauseous taste, however, may be disguised by the admixture of a little lemon juice or cream of tartar, or by the addition of a few drops of sulphuric acid. It is an ingredient in the artificial Cheltenham salt. (See PART II.) D. de Luca has found sodium sulphate remarkably efficient in removing stains or opacity of the cornea, if applied in the form of powdered crystals directly to the eyeball twice daily. (*J. P. C.*, Sept. 1867.) The only uses of sodium sulphate in the arts are to make sodium carbonate and some kinds of glass. It has no U. S. official preparations.

Dose, two drachms to an ounce (7.7 to 31 Gm.).

Off. Prep.—Sodii Sulphas Effervescens, *Br.*

SODII SULPHAS EFFERVESCENS. *Br.*

EFFERVESCENT SODIUM SULPHATE

(sō'di-i sūl'phās ēf-fēr-vēs'cens)

Sodæ Sulphas Effervescens; Effervescent Sulphate of Soda; Natrium Sulfuricum Effervescens; Brausendes Natriumsulfat, *G.*

“Sodium Sulphate, in crystals, 50 ounces (Imperial) or 500 grammes; Sodium Bicarbonate, in powder, 50 ounces (Imp.) or 500 grammes; Tartaric Acid, in powder, 27 ounces (Imp.) or 270 grammes; Citric Acid, in powder, 18 ounces (Imp.) or 180 grammes. Dry the Sodium Sulphate until it has lost 56 per

cent. of its weight; powder the product and mix it with the other ingredients. Place the whole in a dish or pan of suitable form, heated to between 200° and 220° F. (93.3° and 104.4° C.). When the mixture, by aid of careful manipulation of the powder, begins to aggregate, stir it assiduously until it has assumed a granular character; then separate it into granules of uniform and convenient size, by means of suitable sieves. Dry the granules at a temperature not exceeding 130° F. (54.4° C.). The product should weigh about 100 ounces (Imp.) or 1000 grammes.” *Br.*

This was a new official preparation of the British Pharm. 1885, having been introduced in the “Additions.” It is used as an effervescent laxative, in the dose of from one-fourth to one-half ounce (7.7 to 15.5 Gm.) dissolved in cold water and taken while effervescing.

SODII SULPHIS. U. S., *Br.*

SODIUM SULPHITE

(sō'di-i sūl'phis)

“It should contain, in the uneffloresced and air-dried condition, not less than 96 percent. of pure Sodium Sulphite, and should be kept in well-stoppered bottles, in a cool place.” *U. S.* “Sodium Sulphite, $\text{Na}_2\text{SO}_3 \cdot 7\text{H}_2\text{O}$, may be obtained by interaction of sulphurous acid and sodium carbonate.” *Br.*

Natrium Sulfitum, Sulfis Sodicus (Natrius); Sulfite de Soude, *Fr.*; Natriumsulfit, Schwefigsaurer Natron, *G.*

This salt may be prepared by passing sulphurous acid gas into a solution of sodium carbonate, and evaporating out of contact of the air. The sulphurous acid unites with the soda of the carbonate to form sodium sulphite, and the carbon dioxide escapes. After sufficient concentration, the solution is allowed to cool, and the salt crystallizes. A better way, however, is to dissolve a convenient weight of sodium carbonate in a small quantity of water, then pass the sulphurous acid gas through the solution until it is completely saturated, and acid sodium sulphite is formed. The addition of an equal weight of sodium carbonate forms a solution of the neutral sulphite, which is to be evaporated and crystallized. On exposure the salt gradually changes into a sulphate.

Properties.—Sodium sulphite is in “colorless, transparent, monoclinic prisms; odorless, and having a cooling, saline, sulphurous taste. Exposed to the air, the salt effloresces, and is slowly oxidized to sulphate. Soluble in 2 parts of water at 25° C. (77° F.), and in 1.4 parts of boiling water; sparingly soluble in alcohol. When gently heated, the salt softens somewhat, but it does not fuse. Above 100° C. (212° F.) the crystals lose all their water (50 percent.), without fusing or changing their shape. At a red heat the salt fuses to a reddish-yellow

mass of sodium sulphate and sodium sulphide. To a non-luminous flame the salt imparts an intense yellow color. Its aqueous solution is neutral or feebly alkaline to litmus paper. Upon the addition of hydrochloric acid to the salt, sulphur dioxide gas is liberated, which is recognized by its odor, and by its blackening a strip of paper moistened with mercurous nitrate T.S. and held in the escaping gas. If 1 Gm. of the salt be dissolved in 10 Cc. of diluted nitric acid, and the solution heated sufficiently to expel the gases, the liquid should not become turbid (absence of *thiosulphate*). If 1 Gm. of the salt be dissolved in 20 Cc. of diluted hydrochloric acid and heated sufficiently to expel the sulphur dioxide, the remaining solution, after being restored to its original volume, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If to 50 Cc. of tenth-normal iodine V.S., measured from a burette into a glass-stoppered vial (of about 100 Cc. capacity), 0.5 Gm. of the finely powdered crystals of Sodium Sulphite be added, the solution allowed to stand for about an hour, and shaken at frequent intervals, not more than 11.65 Cc. of tenth-normal sodium thiosulphate V.S. should be required to discharge the color of the solution." *U. S.* "In colorless transparent monoclinic prisms, efflorescent in dry air, inodorous, with a saline and sulphurous taste. It is readily soluble in *water*, very sparingly in *alcohol* (90 per cent.). It affords the reactions characteristic of sodium and of sulphites. The aqueous solution has a neutral or faintly alkaline reaction, and if treated with *hydrochloric acid* evolves sulphurous anhydride, but does not become cloudy (absence of *thiosulphate*). Each gramme dissolved in 50 cubic centimetres of *water* should decolorize not less than 77.7 nor more than 81.7 cubic centimetres of the *volumetric solution of iodine*." *Br.* Sulphuric acid added to the solution gives rise to an odor of burning sulphur, owing to the escape of sulphurous acid, and the liquid remains transparent, indicating the absence of lime. Sodium sulphite consists of two atoms of sodium combined with the group SO_3 , characteristic of sulphites, and crystallized with seven molecules of water, $\text{Na}_2\text{SO}_3 + 7\text{H}_2\text{O}$. For methods of determining sodium carbonate in sodium sulphite by C. E. Caspari and M. R. Moffatt see *Proc. A. Ph. A.*, 1902, 429; also *West. Drug.*, 1904, 59.

Uses.—Sodium sulphite has been used in cases of *yeasty vomiting* with remarkable success. The matter vomited in these cases contains two microscopic fungi, called *Sarcina ventriculi* and *Torula cerevisiæ*. The remedy was first used at the suggestion of Graham of London, who supposed that the sulphurous acid, necessarily extricated from the salt in the stomach by the acid of the yeasty matter, would destroy the parasites. Sodium sulphite is sometimes used locally, especially in that species of *aphthous sore mouth* which is attributed to a parasitic vegetable. The wash may be

made of a drachm of the salt to a fluidounce of water. It is said that the solution acts with surprising rapidity, a single application of it sometimes removing the disease in 24 hours. Astrié, an Italian physician, has proposed this salt as a remedy for the constitutional effects of mercury, when used in excess, on the ground that it has the power of rendering the metal soluble. It also has been largely given internally as an antizymotic (see *Sodii Thiosulphas*), but without general success. According to Carey Lea (*Am. J. M. S.*, Jan. 1865), it is partially converted in the system into a sulphate and partially escapes with the urine unchanged.

Dose, of sodium sulphite, fifteen to sixty grains (1.0 to 3.9 Gm.).

SODII THIOSULPHAS. U. S., Br.

SODIUM THIOSULPHATE [*Sodii Hyposulphis*, Pharm. 1890, Sodium Hyposulphite]

(sō'dī-i thī-q-sŭl'phās)

"It should contain not less than 98 percent. of pure Sodium Thiosulphate, and should be kept in well-stoppered bottles." *U. S.*

Hyposulphite of Soda; *Natrum Subsulfurosum* (*Hyposulfurosum*); *Hyposulphis Sodicus*; *Hyposulphite de Soude*, *Fr. Cod.*; *Sulfite sulfuré de Soude*, *Fr.*; *Natrium thiosulfuricum*, *P. G.*; *Natriumthiosulfat*, *Unterschwefligsaures Natron*, *G.*; *Hiposulfito sodico*, *Sp.*

This salt is used in the United States and British Pharmacopœias as a test, and for the formation of the *Volumetric Solution of Sodium Thiosulphate*. It is readily prepared, according to Walchner, by mixing a pound of dry sodium carbonate, in fine powder, with five ounces of sulphur, heating the mixture gradually in a porcelain vessel until the sulphur melts, and stirring the agglutinated mass, still kept hot, in order that every portion of it may come in contact with the air. The sodium sulphide first formed is thus converted into sodium sulphite. This is dissolved in water, and the filtered solution being boiled with sulphur becomes one of sodium thiosulphate, from which, after filtration and concentration, the salt is deposited in crystals. It may be obtained also by digesting the solution of sodium sulphite at a high temperature, but short of ebullition, with finely divided sulphur. Thiosulphuric acid exists only in combination, and its salts were formerly considered simply as sulphuretted sulphites. The true hyposulphurous acid, according to theory, would be H_2SO_2 , while $\text{H}_2\text{S}_2\text{O}_3$ is more properly *thiosulphuric acid*, as it differs from sulphuric acid by the replacement of one oxygen atom by one sulphur atom.

Inasmuch as Schützenberger discovered the true hyposulphurous acid, H_2SO_2 , exact chemical usage would demand that we give the distinguishing name thiosulphuric to what was formerly called hyposulphurous. Schützenberger

himself called the newly-discovered acid *hydrosulphurous*, but this is not characteristic, and the correct name for "sodium hyposulphite" is *sodium thiosulphate*.

Properties.—It is officially described as in "colorless, transparent, monoclinic prisms; odorless, and having a cooling, afterwards bitter taste. Permanent in the air below 33° C. (91.4° F.), but efflorescent in dry air above that temperature; slightly deliquescent in moist air. Soluble in about 0.35 part of water at 25° C. (77° F.); at a boiling heat the solution is rapidly decomposed; insoluble in alcohol; slightly soluble in oil of turpentine. When rapidly heated to 50° C. (122° F.), the salt melts. When slowly heated until it is effloresced, and afterwards to 100° C. (212° F.), it loses all of its water of crystallization (36.3 percent.), and at a red heat is decomposed, sulphur being liberated, while a residue of sodium sulphide and sodium sulphate remains. To a non-luminous flame it imparts an intense yellow color. Its aqueous solution is neutral or faintly alkaline to litmus paper. An aqueous solution of Sodium Thiosulphate readily dissolves many salts of silver (chloride, bromide, iodide, oxide, etc.), and discharges the color of a solution of iodine or of starch iodide. If ferric chloride T.S. be dropped into the aqueous solution (1 in 20), a dark violet color will be produced, which disappears rapidly on agitation. Addition of sulphuric or hydrochloric acid to the aqueous solution liberates from it sulphur dioxide (recognized by its odor, and by its blackening a strip of paper moistened with mercurous nitrate T.S. held in the escaping gas); a white precipitate of sulphur is also formed (distinction from *sulphite* or *bisulphite*). If to 5 Cc. of an aqueous solution of the salt (1 in 10), 3 Cc. of nitric acid be added, the solution cautiously evaporated to dryness on a water-bath, and the residue treated with distilled water, the liquid filtered, and the filtrate and washings evaporated to dryness, this residue should not respond to the Modified Gutzzeit's Test for *arsenic* (see PART III, Test No. 17). The residue from 20 Cc. of an aqueous solution (1 in 20), treated as directed above, when dissolved in 20 Cc. of water and slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). The aqueous solution (1 in 20) should not be rendered turbid by the addition of ammonium oxalate T.S. (absence of *calcium*). An aqueous solution of the salt (1 in 20) should not be colored red by a drop of phenolphthalein T.S. (absence of *caustic alkali* or *carbonate*); nor should a drop of silver nitrate T.S. produce a brown or a black precipitate in 5 Cc. of this solution (absence of *sulphide*). If 1 Gm. of Sodium Thiosulphate be dissolved in 20 Cc. of water, it should require the addition of not less than 39.75 Cc. of tenth-normal iodine V.S. to produce a slight yellow tint." *U. S.* Its solution dissolves

silver chloride and all water-insoluble compounds of that metal, except the sulphide, and that resulting from the decomposition of a silver salt by light. Though without action on potassium iodide, it dissolves iodine, decomposes iodic acid with liberation of iodine, and destroys the blue color of starch iodide. (Brande and Taylor.) In dissolving iodine it forms with it sodium iodide and sodium tetrathionate, as represented by the formula

It dissolves also lead sulphate and iodide, and calcium sulphate, much more freely than does water. (*J. P. C.*, 1864, 363.) Its relations to iodine render it valuable as a means of estimating the quantity of free iodine, for which purpose it is used in the Pharmacopœias in the form of a *volumetric solution*. In consequence of its peculiar solvent properties, it is much used in photography. The photographers employ it for the purpose of dissolving the unchanged silver iodide or bromide from the plate after the action of the light, and thus fixing the image already formed. It is also largely used as an "*antichlor*" in the paper manufacture, to free the paper pulp from the excess of chlorine used in the bleaching. One of the most delicate tests is that of iodine with starch. The blue color produced by the mixture of very small quantities of these two substances in solution is instantly discharged by a solution containing a trace of the thiosulphate. If zinc or iron is dipped into an acidified solution of the thiosulphate, the liberated hydrogen at once reduces the sulphurous oxide which is in the solution to hydrogen sulphide, recognizable by lead acetate paper. This test will serve to show even traces of thiosulphate.

Uses.—Sodium thiosulphate is a very powerful poison to fungi and other low organic forms. Consequently, when added to fermenting mixtures it arrests the process of change. This led G. Polli to suggest its use in certain diseases supposed to be dependent on a fermentation or zymosis in the blood. The theory has seemed plausible to many practitioners, and the remedy has been extensively administered in *pycemia* and in the so-called *zymotic disorders* and allied affections. Although individual experiences corroborating the early successes of Polli have been reported, the general professional verdict is unmistakably adverse. The thiosulphate seems not to be without influence upon the human system. When taken internally it appears to have deoxidizing powers, probably through the passage of the thiosulphuric into sulphuric acid. It has been found, in its action on the urine, to diminish urea and increase uric acid, to increase the sulphates, and to cause the presence of sugar and oxalic acid in the urine. (Kletzensky, *Ann. Thér.*, 1860, p. 109.) With a view to its poisonous influence on the *sarcina ventriculi* which attends *yeasty vomiting*, it has been employed in that complaint and, as a local application, it may be used in all the *parasitic affec-*

tions of the skin and mouth. As the effects of this salt proceed from its acid constituent, other thiosulphates may be substituted, and calcium thiosulphate has been recommended. For the mode of preparing this salt, see *A. J. P.*, 1863.

Dose, ten to twenty grains (0.65 to 1.3 Gm.), three times a day simply dissolved in water, or in the form of syrup. For external use a drachm may be dissolved in a fluidounce of water.

SODIUM. Br.

SODIUM

(sō'dī-ŭm)

"The metal sodium as met with in commerce. It should be preserved in well-stoppered bottles under mineral naphtha." *Br.*

Sodium, *Fr.*; Natrium, *Natronmetall*, *G.*; Sodio, *It.*, *Sp.*

Sodium is a peculiar metal, the hydroxide of which is known as the alkali "soda." It was discovered by H. Davy in 1807, who obtained it in small quantity by decomposing the alkali by the agency of galvanic electricity. Sodium was formerly prepared on a large scale by igniting an intimate mixture of dry sodium carbonate, coal, and chalk. The amount of metal obtained by this method is, however, not over 40 per cent. of the theoretical result. A much improved process was next brought out by Castner (*J. Soc. Chem. Ind.*, 1887, 174), in which an iron carbide, or a mixture of fine iron and coke, is used to reduce the caustic soda, according to the reaction:

The reduction of the sodium hydroxide takes place at a temperature of about 800° C., and is carried out in steel crucibles, each of which holds 5.6 kilos of sodium hydroxide and 1.97 kilos of carbide. The product of the reaction consists of about 4.85 kilos of sodium carbonate and 0.933 kilo of metallic sodium. This latter collects in a receiver connected with the top of the crucible, while the sodium carbonate is dissolved out from the residue and is causticized preparatory to being used again. This process in turn has been replaced by the electrolytic processes. The most successful of these is that of Castner, who uses an electrolyte of fused sodium hydroxide in an iron pot or crucible with an anode of iron and a cathode of copper. The sodium is reduced at a comparatively low temperature, and is ladled from the vessel into moulds. The process is carried out at present on a large scale by the Niagara Electro-Chemical Co., and at Oldbury, England, and several places in Germany. The production of sodium (all by the electrolytic process) in the United States in 1904 amounted to 1,320,000 pounds valued at \$170,000.

Sodium is a soft, malleable, ductile solid, of a silver-white color. It possesses the metallic lustre in a high degree, when protected from the action of the air, by which it is quickly tar-

nished and oxidized. Its sp. gr. is 0.97, and its fusing point 95.6° (204° F.). Its chemical affinities resemble those of potassium, but are less energetic. Like potassium, it has a strong attraction for oxygen. When thrown upon cold water it instantly fuses into a globule without inflaming, and traverses the surface in different directions with rapidity; on warm water it inflames. In both cases the water is decomposed, hydrogen is liberated, and sodium hydroxide generated. Like potassium, if exposed with a bright surface to the air, it undergoes a slow combustion, which renders it luminous in the dark. It combines with oxygen to form the monoxide, Na_2O , and a peroxide, Na_2O_2 . This latter oxide is always formed when the metal is burned in the open air. "A soft metal, rapidly oxidizing in the air, but showing a bright metallic surface when freshly cut. It violently attacks water or alcohol (90 per cent.), with evolution of hydrogen, little or no insoluble matter remaining. It imparts an intense yellow color to flame. Each gramme very cautiously added to water affords a solution which should require for neutralization at least 42.6 cubic centimetres of the volumetric solution of sulphuric acid." *Br.*

Sodium is a constituent of many important medicinal preparations. Sodium salts are characterized by communicating to the blowpipe flame a rich yellow color, and by not being precipitable by any reagent except potassium metantimoniate. Sodium monoxide consists of two atoms of sodium and one atom of oxygen. This reacts with water to form sodium hydroxide (caustic soda),

The dioxide (or peroxide), Na_2O_2 , is now manufactured on a large scale from the metal, and used as a substitute for hydrogen peroxide in bleaching processes. It forms a canary-yellow powder, which decomposes rapidly in the presence of moisture.

The official combinations containing sodium are the solutions of sodium hydroxide and chlorinated soda, sodium acetate, arsenate, benzoate, bicarbonate, bisulphite, borate, bromide, carbonate, chlorate, chloride, citrate, hydroxide, hypophosphite, iodide, nitrate, nitrite, phenolsulphonate, phosphate, pyrophosphate, salicylate, sulphate, sulphite, thiosulphate, and potassium and sodium tartrate.

Off. Prep.—Liquor Sodii Ethylatis, *Br.*

SPARTEINÆ SULPHAS. U. S.

SPARTEINE SULPHATE

(spär-tē-i'næ sŭl'phās)

"The sulphate $[\text{SO}_2(\text{OH})_2 \cdot \text{C}_{15}\text{H}_{28}\text{N}_2 + 5\text{H}_2\text{O}]$ of an alkaloid obtained from *Scoparius*. Sparteine Sulphate should be kept in well-stoppered, amber-colored vials." *U. S.*

Sulfate de Sparteïne, *Fr. Cod.*; Sparteinum Sulphuricum; Sparteinsulfat, Schwefelsaures Spartein, *G.*; Sulfato de esparteina, *Sp.*

This alkaloidal salt, prepared from Scoparius (see page 1103) is officially described as in "colorless, rhombohedral crystals, or a crystalline powder; odorless, and having a slightly saline and somewhat bitter taste. It crystallizes with varying amounts of water of crystallization, but when recrystallized from a solution in diluted alcohol it contains 5 molecules of water. Soluble in 1.1 parts of water, and in 2.4 parts of alcohol at 25° C. (77° F.); insoluble in ether and chloroform. When heated to 110° C. (230° F.), the salt loses all of its water of crystallization (21.3 percent.), and when anhydrous, melts at 136° C. (276.8° F.). It is hygroscopic, and its aqueous solution has an acid reaction upon blue litmus paper.

If 25 Cc. of ether be added to about 0.1 Gm. of Sparteine Sulphate in a test-tube, followed by a few drops of diluted ammonia water, avoiding an excess, and if an ethereal solution of iodine (1 in 50) be afterwards added until the liquid, when shaken, turns from an orange to a dark reddish-brown color, the bottom and sides of the test-tube will, after a short time, be coated with minute, dark greenish-brown crystals. Barium chloride T.S., in an aqueous solution of Sparteine Sulphate, produces a white precipitate insoluble in hydrochloric acid. If a solution of potassium ferrocyanide (1 in 20) be added to a solution of the salt, a yellow precipitate is produced. Sulphuric acid, when added to Sparteine Sulphate, should not become colored (absence of sugar and other readily carbonizable organic impurities). On shaking 0.05 Gm. of Sparteine Sulphate, in a test-tube, with 5 Cc. of potassium hydroxide T.S., the liquid will at first be turbid, and small drops of Sparteine will gradually collect on the surface. If a strip of moistened red litmus paper be suspended in the mouth of the test-tube, and a gentle heat then applied, the test paper will gradually acquire a blue color, but no odor of ammonia should be perceptible (absence of ammonium salts)." U. S. G. Marque (*J. P. C.*, xxx. 555) states that if a small quantity of sparteine sulphate be mixed with about one-third of its weight of chromium trioxide, and gently heated in a porcelain dish, the mass will soon turn green and emit a strong odor resembling coniine. Moureu and Villier (*Bull. Soc. Chim.*, 1903 (6), 12, 545) confirm Stenhouse's formula for sparteine sulphate, $C_{15}H_{25}Na_2H_2SO_4 + 5H_2O$.

According to S. Solis-Cohen the reason that sparteine has proved so unsatisfactory practically, is because it is not used in a sufficient dose. He affirms that in serious cases from one-half to two grains (0.032 to 0.13 Gm.) should be given hypodermically every second hour for three or four doses, after which the drug should be given by the mouth in lessening dose until after two or three days one grain to one and one-half grains (0.065 to 0.096 Gm.) is taken daily by the mouth. The effect

upon the pulse tension must be carefully watched and the dose modified according to circumstances.

For an account of the physiological and therapeutic action of this alkaloid, see Scoparius.

Dose, from one-sixth to one-half grain (0.01 to 0.032 Gm.).

SPIGELIA. U. S.

SPIGELIA [Pinkroot]

(spi-ḡē'li-ḡ)

"The dried rhizome and roots of *Spigelia marilandica* Linné (Fam. *Loganiaceæ*)."
U. S.

Maryland, Carolina or Indian Pink, Worm-grass or Worm-weed, Star-bloom; Spigelle du Maryland, Fr.; Marylandische Spigelle, Spigelle, G.; Spigella, It.

Two species of *Spigelia* have attracted attention as anthelmintics,—*S. anthelmia* of South America and the West Indies, and *S. marilandica* of this country. *Spigelia Anthelmia*, L., of South America is an annual plant, from one to two feet in height, with thin, shortly petioled leaves, those of the lower stem being lanceolate, those above varying from very broadly lanceolate to ovate, with a distinct tendency to a rhomboidal outline and attaining a length of over four inches. It is much used as a powerful and certain anthelmintic in its native country, and its rhizome is said to have appeared in the European markets. The only specimens which we have seen, however, have been the whole dried plant, of which the attached rhizomes are much smaller and the rootlets much finer than in the North American species. It is affirmed that in overdoses this rhizome is a powerful poison, which has caused death not only in the domestic animal but also in man.

Spigelia marilandica, L., *Syst. Ed.* (1767) 734; Willd., *Sp. Plant.* i. 825; Bigelow, *Am. Med. Bot.*, i. 142; Barton, *Med. Bot.*, ii. 75; B. & T. 180.—The *Carolina pink* is an herbaceous perennial plant. The stems, several of which rise from the same rhizome, are simple, erect, four-sided, nearly smooth, and from twelve to twenty inches high. The leaves are opposite, sessile, ovate-lanceolate, acuminate, entire, and smooth, with the veins and margins slightly pubescent. Each stem terminates in a one-sided spike, and supports from four to twelve flowers with very short peduncles. The calyx is persistent, with five long, subulate, slightly serrate leaves, reflexed in the ripe fruit. The corolla is funnel-shaped, and much longer than the calyx, with the tube inflated in the middle, and the border divided into five acute, spreading segments. It is of a rich carmine color externally, paler at the base, and orange-yellow within. The edges of the segments are slightly tinged with green. The stamens, though apparently very short, and inserted into the upper part of the tube between the segments, may be traced down its internal sur-

face to the base. The anthers are oblong, heart-shaped; the ovary superior, ovate; the style about the length of the corolla, and terminating in a linear fringed stigma projecting considerably beyond it. The capsule is double, consisting of two cohering, globular, one-celled portions, with many seeds.

The plant is a native of our Southern and Southwestern States, being seldom found north of the Potomac. It grows in rich soils on the borders of woods, and flowers from May to July. The root is the only part recognized in the Pharmacopœias. The drug was formerly collected in Georgia and the neighboring States by the Creek and Cherokee Indians, who disposed of it to the white traders. The whole plant was gathered and dried, and came to us in bales or casks. After the emigration of the Indians, the supply of spigelia from this source very much diminished, and at one time it nearly if not quite ceased. The consequence was for a time a great scarcity, and an increase in the price of the drug; but a new source of supply was opened from the Western and Southwestern States, and it is now again plentiful. As we receive spigelia at present, it consists chiefly if not exclusively of the root, without the stems and leaves. We have been informed that most of it comes in casks or bales from St. Louis by the way of New Orleans. That contained in casks is to be preferred, as less liable to be damp and mouldy.

Properties.—Pinkroot consists of numerous slender, branching, crooked, wrinkled fibres, from three to six inches long, attached to a knotty head or caudex, which exhibits traces of the stems of former years. It is brownish or yellowish-brown externally, of a faint, peculiar odor, and a sweetish, slightly bitter, not very disagreeable taste. On microscopic examination the middle layer is seen to be very well developed and the nucleus sheath wanting. It is officially described as a "rhizome of oblique and sharply flexuous growth, somewhat branched, 1.5 to 5 Cm. long, 2 to 4 Mm. in diameter; externally dark purplish-brown or blackish, the upper surface knotty from approximate stem-bases bearing cup-shaped scars; the lower surface with numerous long, rather coarse, finely branched roots; fracture short, showing a yellowish wood and a dark pith; odor somewhat aromatic; taste bitter and pungent." *U. S.*

The virtues of spigelia are extracted by boiling water. The root, analyzed by Feneulle, yielded a fixed and volatile oil, a small quantity of resin, a bitter substance supposed to be the active principle, a mucilaginous saccharine matter, albumen, gallic acid, the malates of potassium and calcium, etc., and woody fibre. The principle upon which the virtues of the root are thought to depend is brown, of a bitter nauseous taste, like that of the purgative matter of the leguminous plants, and when taken internally produces vertigo and a kind of intoxication. An analysis of the root by R. H. Stabler yielded as results a bitter uncrystal-

lizable principle upon which the virtues of the medicine are supposed to depend, a little volatile oil, tannic acid, inert extractive, wax, resin, lignin, and salts of sodium, potassium, and calcium.

Stabler found that the active principle is acrid and bitter, soluble in water and alcohol, insoluble in ether, not volatilizable without change, uncrystallizable, neutral, and deliquescent. W. L. Dudley (*Am. Chem.*, vol. i. p. 150), on the contrary, found that the active principle of spigelia is a volatile alkaloid. He made it by distilling the ground root with milk of lime over a paraffin bath, and collecting the distillate in hydrochloric acid. After evaporation to dryness, the residue is taken up with alcohol and crystallized out of solution. He compared the reactions of this alkaloid, which he called *spigeline*, with those of nicotine, coniine, and lobeline. Spigeline yields a brownish-red precipitate with a solution of iodine in potassium iodide, a white crystalline precipitate with potassium-mercuric iodide, and a white flocculent precipitate with meta-tungstic acid. Boorsma (*P. J.*, 1898, 89) found 0.0005 Gm. of *spigeline* to be lethal to guinea pigs.

The stalks of the dried plant are oval below the first pair of leaves, and then become obscurely four-sided. The leaves, when good, have a fresh greenish color, and an odor somewhat like that of tea. In taste they resemble the root, and they afforded to Feneulle nearly the same principles. The quantity, however, of the bitter substance was less, corresponding with their inferior efficacy. This circumstance should cause their rejection from commerce, as the inequality in power of the two portions of the plant would lead to uncertainty in the result, when they were both employed. It is frequently necessary to separate the spigelia from various adulterant roots. Among the most important of these may be mentioned the roots of certain small vines which frequently twine around the spigelia stem; these roots can be distinguished by their being long, slender, crooked, yellowish, thickly set with short capillary fibres, and much smaller and lighter-colored than is pinkroot; the large light-colored rhizomes of various species of *Ruellia*, distinguished by their readily separable bark and few coarse roots; the rhizomes of *Phlox ovata*, L., which are smooth, lacking the cup-shaped scars of spigelia, and have straighter, thicker, and less wiry rootlets. According to Henry G. Greenish, *Phlox root* can at once be separated microscopically from spigelia root by the presence in it of numerous stone-cells, and also of cells more or less completely filled by granular cystoliths. (*P. J.*, xxi.) The activity of spigelia is somewhat diminished by time.

Uses.—Spigelia is generally considered among the most powerful anthelmintics. In the ordinary dose it usually produces little sensible effect on the system; more largely given it acts as a cathartic, though unequal and uncertain in its operation; in overdoses it is said to cause vertigo, dimness of vision, dilated pupils,

spasms of the facial muscles and of the eyelids, and even general convulsions. The death of two children who expired in convulsions was attributed to it by Chalmers. H. A. Hare (*Med. News*, March, 1887) has found that in the lower animals it produces symptoms similar to those just described, namely, dilatation of the pupil, exophthalmia, strabismus, progressive muscular weakness of spinal origin, cardiac depression, and death from failure of respiration. The narcotic effects are said to be less likely to occur when the medicine purges, and to be altogether obviated by combining it with cathartics. The danger from its employment cannot be great, as it is in very general use in the United States, in both regular and domestic practice, and we never hear at present of serious consequences. Its effects upon the nervous system have been erroneously conjectured to depend on other roots sometimes mixed with the genuine. The vermifuge properties of spigelia, first learned from the Cherokee Indians, were made known to the medical profession by Lining, Garden, and Chalmers of South Carolina.

It may be given in substance or infusion. The practice of preceding its use by an emetic has been generally abandoned. It is frequently given in combination with calomel. The infusion, however, is a more common form of administration. It may be made by infusing half a troyounce of the root in a pint of boiling water. It is usually combined with senna or some other cathartic, to insure its action on the bowels. A preparation much sold under the name of *worm tea* consists of spigelia, senna, manna, and savin, mixed together, in various proportions, to suit the views of different individuals. Spigelia is also very often given in the form of fluidextract.

Dose, of the powdered root, for a child three or four years old, ten to twenty grains (0.65 to 1.3 Gm.), for an adult, one to two drachms (3.9 to 7.7 Gm.), to be repeated morning and evening for several days successively, and then followed by a brisk cathartic.

Off. Prep.—Fluidextractum Spigeliæ, *U. S.*

SPIRITUS.

SPIRITS

(spir'î-tûs)

Alcoolats, *Fr.*; Gelste, *G.*; Spirito, *It.*

Spirits, as the term is here used, are alcoholic solutions of volatile principles formerly in general procured by distillation, but now frequently prepared by simply dissolving the volatile principle in alcohol or diluted alcohol. The distilled spirits are prepared chiefly from aromatic vegetable substances, the essential oils of which rise with the vapor of alcohol and condense with it in the receiver. Some of the oils, however, will not rise at the temperature of boiling alcohol, but may be distilled with water. In this case it is necessary to employ diluted alcohol or proof spirit, with the water of which

the oil comes over in the latter part of the process. As the proof spirit of commerce is often impregnated with foreign matters, which give it an unpleasant flavor, it is better to use alcohol which has been carefully rectified, and to dilute it with the due proportion of water, as directed by the *U. S. Pharmacopœia*. In preparing the spirits, care should be taken to avoid the color and empyreumatic flavor arising from the decomposition of the vegetable matter by heat. Sufficient water must, therefore, be added to cover the vegetable matter after the alcohol shall have been distilled, and, as a rule, the heat should be applied by means of a water bath, or of steam. The aromatic should be macerated for some days with the alcohol before being submitted to distillation, as the oil, being thus dissolved, rises more readily with the spirituous vapor than when confined in the tissue.

The aromatic spirits are used chiefly to impart a pleasant odor and taste to mixtures, and to correct the nauseating and griping effects of other medicines. They serve also as carminatives in *flatulent colic*, and as agreeable stimulants in *debility of the stomach*.

The *U. S. P.* (8th Rev.) did not retain the following spirits of the *U. S. P.* 1890: Spiritus Aurantii, Spiritus Limonis, Spiritus Myrciæ, Spiritus Myristicæ, and Spiritus Phosphori.

SPIRITUS ÆTHERIS. *U. S.*, *Br.*

SPIRIT OF ETHER

(spir'î-tûs æ'thê-ris)

Liquor Anodynus Mineralis Hoffmanni; Ether officinal alcoolisé, *Fr. Cod.*; Ether sulfurique alcoolisé, Liqueur d'Hoffmann, *Fr.*; Spiritus Æthereus, *P. G.*; Aetherweingeist, Hoffmannsche Tropfen, *G.*; Etere con alcool, Liquore anodino di Hoffmann, *It.*; Eter sulfurico alcoolizado, Licor anodino mineral de Hoffmann, *Sp.*

* "Ether, three hundred and twenty-five cubic centimeters [or 10 fluidounces, 475 minims]; Alcohol, six hundred and seventy-five cubic centimeters [or 22 fluidounces, 396 minims], to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix them." *U. S.*

"Ether, 10 fl. ounces (Imperial measure) or 500 cubic centimetres; Alcohol (90 per cent.), 1 pint (Imp. meas.) or 1000 cubic centimetres. Mix." *Br.*

This preparation is merely ether diluted with about twice its volume of alcohol. Although introduced into the *U. S. P.* 1880, it does not seem to have been employed to any extent, and it might have been dropped with advantage at a later revision. The corresponding preparation of the German Pharmacopœia contains less ether, being made of one part of ether to three parts of alcohol, both by weight. Prepared with materials of proper strength, its sp. gr. is 0.806 to 0.811. *Br.* Its medicinal properties are similar to those of ether.

Dose, one to three fluidrachms (3.75 to 11.25 Cc.), properly diluted with sweetened water.

Off. Prep.—Tinctura Lobeliæ Ætherea, *Br.*

SPIRITUS ÆTHERIS COMPOSITUS.

U. S., Br.

COMPOUND SPIRIT OF ETHER

(spir'-i-tūs æth'-eris cōm-pōs'-i-tūs)

Hoffmann's Anodyne; Liqueur Nervine de Bang, *Fr.*; Zusammengesetzter Aetherweingeist, *G.*

* "Ether, *three hundred and twenty-five cubic centimeters* [or 10 fluidounces, 475 minims]; Alcohol, *six hundred and fifty cubic centimeters* [or 21 fluidounces, 470 minims]; Ethereal Oil, *twenty-five cubic centimeters* [or 406 minims], to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix them." *U. S.*

"Ether, 5½ *fl. ounces* (Imperial measure) or 137.5 cubic centimetres; Alcohol (90 per cent.), 78 *fl. ounces* (Imp. meas.) or 1950 cubic centimetres; Sulphuric Acid, 36 *fl. ounces* (Imp. meas.) or 900 cubic centimetres; Distilled Water, 1½ *fl. ounces* (Imp. meas.) or 37.5 cubic centimetres; Sodium Bicarbonate, *a sufficient quantity*. Gradually mix the Sulphuric Acid with *forty fluid ounces* (Imp. meas.) or one thousand cubic centimetres of the Alcohol; let the mixture stand for twenty-four hours. Then distil slowly until a thermometer, the bulb of which is within the liquid, indicates a temperature of 341° F. (171.6° C.). Pour the distillate into a separator, and, after separation is complete, remove the lower layer. Add the Distilled Water to the upper layer, and also, gradually, Sodium Bicarbonate, until, after agitation, the liquid is nearly neutral to *litmus paper*. Separate the ethereal liquid, and add to it the Ether and *thirty-eight fluid ounces* (Imp. meas.) or nine hundred and fifty cubic centimetres of the Alcohol. Filter." *Br.*

This preparation is an alcoholic solution of ether, containing a little heavy oil of wine. In the U. S. formula, determinate quantities of ether, alcohol, and oil are taken, the ether having half the volume of the alcohol. The formula of the U. S. P. (8th Rev.) is practically the same as that of the U. S. P. 1880. In the last revision of the British Pharmacopœia this preparation was improved according to the suggestions of W. Inglis Clark (*P. J.*, 1896, 183); but the process still yields an uncertain product, containing ether, alcohol, and a trace of oil of wine.

Properties.—This spirit is a colorless, volatile liquid, having a burning, slightly sweetish taste, and the peculiar odor of ethereal oil. If it have an empyreumatic odor, it has been badly prepared. Its sp. gr. is 0.815, according to the U. S. Pharmacopœia of 1870; the present official preparation contains a little less oil of wine. When pure, it is wholly volatilized by heat, and devoid of acid reaction. It becomes milky on being mixed with water, owing to the precipitation of the ethereal oil; but this change does not prove its goodness, as the same property may be given to the spirit of ether by the addition of various fixed oils. This sophistication may be detected by mixing the sus-

pected preparation with water, drawing a piece of paper over the surface of the liquid to absorb the oily globules, and exposing the paper to heat. If the globules are fixed oil, the greasy stain will remain; if ethereal oil, the stain will disappear. When fixed oils are used to adulterate this preparation, the milkiness is generally too great, and not like the translucent leaden milkiness of the genuine article. (Squibb.) "A colorless mobile liquid with characteristic ethereal odor and taste. Specific gravity 0.808 to 0.812. It gives an opalescent solution when mixed with twice its volume of *water*. 2 or 3 cubic centimetres evaporated spontaneously on a watch-glass should not yield a residue having an unpleasant odor (absence of empyreumatic impurities)." *Br.*

It is much to be regretted that our manufacturing chemists do not follow the Pharmacopœia in making compound spirit of ether. In rectifying crude ether, the distillation is continued as long as the ether comes over of the proper specific gravity, after which the manufacturer has been in the habit of changing the receiver and obtaining an additional distillate, consisting of ether and alcohol, mixed with a small quantity of ethereal oil. Now, it is this second distillate, variously modified by the addition of alcohol, ether, or water, so as to make it conform in taste, odor, opalescence, etc., to a standard preparation, kept by the manufacturer, that is sold as Hoffmann's anodyne. Nothing could be more uncertain in its results than a proceeding like this, and we cannot be surprised that the medicine as obtained from different apothecaries varies very much in properties, and often disappoints the expectations of the physician. The chief excuse for the departure from the official directions is the costliness of the ethereal oil; but, even were this much greater than it really is, the excuse would not be valid, and it cannot be justified, on any principle of morality, to sell under the official title a preparation which has no claim to it whatever.

Uses.—This preparation is intended as a substitute for the anodyne liquor of Hoffmann, which it closely resembles when properly prepared. In addition to the stimulating and antispasmodic qualities of ether which it contains, it possesses anodyne properties, highly useful in *nervous irritation* and in want of sleep from this cause. These additional virtues are probably derived from the official oil of wine, which Physick and Dewees found, dissolved in alcohol, very efficacious in certain disturbed states of the system, as a tranquillizing and anodyne remedy. Such indeed, are the generally admitted effects of compound spirit of ether, when made with a due admixture of the ethereal oil. This preparation is on many occasions a useful adjunct to laudanum, to prevent *nausea*.

Dose, from thirty minims to two fluidrachms (1.8 to 7.5 Cc.), to be given in sweetened water.

SPIRITUS ÆTHERIS NITROSI.

U. S., Br.

SPIRIT OF NITROUS ETHER [Sweet Spirit of Nitre]

(spîr'î-tūs æ'thē-ris nî-trō'sî)

"An alcoholic solution of Ethyl Nitrite [NO. $\text{OC}_2\text{H}_5 = 74.51$], yielding, when freshly prepared and tested by the process given below, not less than 4 percent. of ethyl nitrite." *U. S.*
 "An alcoholic solution containing ethyl nitrite, aldehyde, and other substances." *Br.*

Spiritus Nitri Dulcis; *Spiritus Ætheris Nitrici*; *Spiritus Nitrico-æthereus*; *Æther Azoteux Alcoolisé*; *Liqueur anodine nitreuse*, *Fr.*; *Spiritus Ætheris nitrosi*, *P. G.*; *Versüßter Salpetergeist*, *G.*; *Etere nitroso officinale*, *Spirito d'etere nitroso*, *It.*; *Espiritu de nitro dulce*, *Sp.*

* "Sodium Nitrite, one hundred grammes [or 3 ounces av., 231 grains]; Sulphuric Acid, forty cubic centimeters [or 1 fluidounce, 169 minims]; Monohydrated Sodium Carbonate, six-tenths of a gramme [or 9 grains]; Potassium Carbonate, completely deprived of water by drying, three grammes [or 46 grains]; Alcohol, Water, each, a sufficient quantity. Mix the Sulphuric Acid with one hundred and twenty cubic centimeters [or 4 fluidounces, 28 minims] of Water, cool the liquid, add eighty-five cubic centimeters [or 2 fluidounces, 420 minims] of Alcohol previously diluted with an equal volume of Water, and introduce the solution into a 1000 Cc. [or 2 pint] flask, surrounded by a mixture of ice and water. Dissolve the Sodium Nitrite in two hundred and eighty cubic centimeters [or 9 fluidounces, 225 minims] of Water, filter, and, having poured the filtrate into a separatory funnel, allow the liquid to slowly drop into the flask containing the acid mixture. When all has been added and the reaction is complete, allow any crystals which may have formed to settle at the bottom of the flask, and decant the cold mixture of ethyl nitrite and aqueous solution quickly to the previously cleaned separatory funnel, and draw off and discard the aqueous liquid. Wash the separated ethyl nitrite, first, with twenty cubic centimeters [or 325 minims] of ice-cold Water, and then remove any traces of acid by washing it with fifteen cubic centimeters [or 243 minims] of ice-cold Water, in which the Monohydrated Sodium Carbonate has previously been dissolved. Carefully separate the ethyl nitrite from the aqueous liquid, and agitate it in a well-stoppered vial with the Potassium Carbonate to remove traces of water. Then cool the liquid, decant, and pour the ethyl nitrite immediately into a tared bottle containing five hundred grammes [or 17 ounces av., 279 grains] of Alcohol. Ascertain the weight of the ethyl nitrite poured into the Alcohol by noting the increase in weight of the tared bottle and contents, and then add enough Alcohol to make the mixture weigh twenty-two times the weight of the ethyl nitrite added. Lastly, transfer the product to small,

well-stoppered, dark amber-colored vials, and keep these in a cool place, remote from lights or fire." *U. S.*

"Nitric Acid, 3 fl. ounces (Imperial measure) or 150 cubic centimetres; Sulphuric Acid, 2 fl. ounces (Imp. meas.) or 100 cubic centimetres; Copper, 2 ounces (Imp.) or 100 grammes; Alcohol (90 per cent.), a sufficient quantity. To one pint (Imp. meas.) or one thousand cubic centimetres of the Alcohol add gradually the Sulphuric Acid, stirring them together; then stir in two and a half fluid ounces (Imp. meas.) or one hundred and twenty-five cubic centimetres of the Nitric Acid; the mixture being made in a retort or flask, in which the copper has been placed, and to which a thermometer is fitted; attach to the retort or flask an efficient condenser and receiver, the latter containing twenty fluid ounces (Imp. meas.) or one thousand cubic centimetres of the Alcohol, and, applying heat gently, distil at a temperature commencing at 170° F. (76.7° C.), and rising to 175° F. (79.4° C.), but not exceeding 180° F. (82.2° C.), until the volume of liquid in the receiver has been increased to thirty-two fluid ounces (Imp. meas.) or to sixteen hundred cubic centimetres, the receiver and the condenser being kept cool with ice-cold water. Then withdraw the source of heat, and having allowed the contents of the retort to cool, introduce the remaining half-ounce (Imp. meas.) or twenty-five cubic centimetres of Nitric Acid, and resume the distillation as before, until the liquid in the receiver has been increased to thirty-four fluid ounces (Imp. meas.) or seventeen hundred cubic centimetres. Mix this liquid with one pint (Imp. meas.) or one hundred cubic centimetres of the Alcohol, or with as much as will make the product contain 2½ per cent. of ethyl nitrite when tested as described in the following paragraph. Preserve the Spirit of Nitrous Ether in well-closed vessels; preferably in a cool dark place, and in small bottles." *Br.*

Test.—"1 volume agitated briskly at intervals during 5 minutes in a brine-charged nitrometer, with 1 volume of solution of potassium iodide and 1 volume of diluted sulphuric acid, should yield, at the normal temperature (60° F. or 15.5° C.) and pressure (30 inches or 760 millimetres of mercury), and when freshly prepared, at least 6½, but not more than 7, volumes of nitric oxide gas, corresponding to at least 2½ parts by weight of ethyl nitrite in 100 parts by weight of the Spirit; and even after it has been kept for some time, and the vessel containing it has occasionally been opened, it should yield not much less than 5 times its volume of the gas, corresponding to nearly 2 per cent. by weight of ethyl nitrite or a minimum of 1½ per cent." *Br.* The U. S. P. (8th Rev.) and the Br. Ph. 1898 quantitative test is based on Allen's method, differing only in the relative quantities of the reagents. (See p. 1166; also paper by Curtman, *Proc. Missouri Pharm. Assoc.*, July, 1892; *A. J. P.*, 1898, 273.)

Assay. U. S. (8th Rev.)—"Transfer about 30 Gm. of the Spirit of Nitrous Ether, which has been previously shaken with 0.5 Gm. of potassium bicarbonate, to a tared 100 Cc. measuring flask, and weigh it accurately. Add sufficient alcohol to bring the volume to exactly 100 Cc., and mix thoroughly. Introduce into a nitrometer (see Part III, Gasometric Estimations) exactly 10 Cc. of the alcoholic solution, followed by 10 Cc. of potassium iodide T.S., and afterwards by 10 Cc. of normal sulphuric acid V.S. When the volume of gas has become constant (within 30 to 60 minutes), note the volume of gas collected. Multiply this volume in Cc. by 0.307, and divide the product by the original weight of the Spirit of Nitrous Ether. At standard temperature and pressure, the quotient will represent the percentage of ethyl nitrite in the liquid. The temperature correction is one-third of one percent. of the total percentage just found for each degree, additive if temperature is below, subtractive if above, 25° C. (77° F.). The barometric correction is four-thirtieths of one percent. for each millimeter, additive if above, subtractive if below, 760. When assayed according to the above method, Spirit of Nitrous Ether should yield not less than 4 percent. of ethyl nitrite." U. S.

Allen's Test for Ethyl Nitrite.—A nitrometer¹ should be filled with strong brine, and 5 Cc. of the sample to be tested should be placed in the cup of the nitrometer, and allowed to enter through the tap, taking care that no air gets in at the same time. Five Cc. of a strong solution of potassium iodide is next allowed to enter, and this is followed by about 5 Cc. of dilute sulphuric acid. Effervescence immediately ensues, and, if the tube be vigorously agitated at intervals, the reaction will be complete in five minutes, when the level of the liquid in the two limbs of the nitrometer is adjusted, and the volume of nitrogen dioxide gas read off. If the volume of gas evolved be small, another 5 Cc. of the sample should be let into the nitrometer, and the agitation repeated. The calculation is the same as in Eykman's process, the reaction being:

When strictly accurate results are not required, the volume of gas need not be corrected for variations of pressure, temperature, and tension of aqueous vapor, and if these considerations be omitted the calculation will be much simplified. Thus, if 0.030 gramme of nitrogen dioxide (representing 0.075 gramme of $C_2H_5NO_2$) under the ordinary conditions of pressure and temperature be taken to measure 23.55 Cc., then

$$\frac{\text{volume of gas in Cc.} \times 0.3185}{\text{measure of sample in Cc.} \times \text{density of sample}} = \text{percentage by weight of } C_2H_5NO_2.$$

If the density of the sample be omitted from the equation, the result will be the number of grammes of ethyl nitrite per 100 Cc. of the sample.

The nitrometer method has been proved to give very good results with pure sodium nitrite (prepared from silver nitrite) employed in known amount. The results with spirit of nitrous ether are somewhat higher than those given by Eykman's method, the difference being least when sodium chloride is employed in the latter process and time is given for the ferrous solution to react thoroughly on the solution of ethyl nitrite. The results by the iodide method are almost certainly more accurate than those by Eykman's process. With most specimens of sweet spirit of nitre a considerable amount of nitric oxide is produced (and iodine liberated) before adding the acid, the reaction probably depending on the presence of free acid in the sample. The results obtained in the nitrometer are remarkably constant, and the method furnishes a very easy means of assaying sweet spirit of nitre with considerable accuracy, which is further increased if a correction of 1.5 Cc. (= 0.0048 gramme of $C_2H_5NO_2$) be made for solubility of the gas. The process has the advantage of great ease and rapidity, and actually measures the nitrous compounds present in the sample, instead of leaving their proportions to be inferred from a more or less complex reaction, such as the reduction of permanganate, and others.

The official spirit of nitrous ether is a mixture of nitrous ether or ethyl nitrite, $C_2H_5NO_2$, and alcohol (rectified spirit). For many years, spirit of nitrous ether has been made by acting on alcohol with nitric acid, and the present British process and that of the U. S. P. 1880 are constructed on this plan. The U. S. P. 1890 and 8th Rev. processes differed essentially; in these, the use of nitric acid is abandoned, sodium nitrite being substituted as the source of the nitrous compound. Nitrous ether is always generated by the reaction of nitric acid with alcohol; and it matters not whether the alcohol be mixed with nitric acid directly, or with the materials for generating it, namely, nitre and sulphuric acid. In the U. S. Pharmacopœia of 1850 the requisite nitric acid was obtained by using the materials for generating it, namely, potassium nitrate and sulphuric acid; for details of the process, see U. S. D., 14th ed., p. 1445.

In the U. S. 1860 process, which was modelled after the plan of Squibb, the nitric acid and alcohol were directly mixed in a retort. The liquid condensed in the receiver was mixed with potassium carbonate, and again distilled, in order to free it from the acid which had come over with the nitrous ether, and, being too strong with ether to meet the purposes required, was diluted with alcohol, and thus brought to the state of *spirit* of nitrous ether. It was a great improvement over the formula of earlier Pharmacopœias,

¹ For a simple form of nitrometer, see P. J., 1887, p. 763, or *Proc. A. Ph. A.*, 1887, p. 19; also *Ephem.*, 1889, p. 1202; O. & D., 1901, 1045.

and had the merit of insuring a preparation of definite strength. But in the Pharmacopœia of 1870 the British process was substituted, as even better than it.

The U. S. 1880 process differed in several particulars from those formerly official. Copper was no longer used. The use of this metal originated with Redwood, under the impression that the nitrous radical was liberated by it and enabled to unite more readily with the ethyl of the alcohol, to form ethyl nitrite. Our experience is that upon the small scale the copper served a useful purpose in controlling and moderating the reaction, but excellent results have been obtained by substituting broken glass, and we have obtained quite as large a yield of the peculiar ether when the copper was omitted. The nitric acid was not added in two portions, but the whole quantity was mixed with the sulphuric acid and alcohol at first. This was an improvement, in our opinion. The direction to "heat rapidly, by means of a water-bath, until strong reaction occurs and the temperature reaches 80° C. (176° F.)," was likely to cause loss in the hands of the inexperienced through excessive action, and inability to condense all the vapor of ethyl nitrite which would be suddenly generated. A temperature of 72° C. (161.6° F.), in our experience, was simply sufficient to start the reaction, and as soon as effervescence took place the heat should have been *at once removed*, and not reapplied until the reaction slackened, so that a uniform and not an excessive reaction might be maintained. The greatest change was, however, in purifying the distillate by agitating it with ice cold distilled water, separating the ethereal layer and mixing it with alcohol, so that the finished product should contain 5 per cent. by weight of the crude ethyl nitrite. It is very doubtful, in our opinion, whether anything was removed by the agitation with cold water except some of the alcohol. As aldehyde and hydrocyanic acid are both soluble in ethyl nitrite, and as alcohol must be added subsequently, the advantage of the separation of the nitrous ether in this way was not very apparent, and when it is considered that ethyl nitrite is soluble in water and more soluble in alcohol, some of the most valuable portion of the distillate must have been wasted by being dissolved in cold water. A thoroughly effective method of separating ethyl nitrite from its solution in alcohol and water is yet to be discovered. Some manufacturers agitate the distillate with a saturated solution of calcium chloride to separate the ethyl nitrite, and the British Pharmacopœia once used this method as a test.¹

The U. S. P. 1890 process overcame these objections by generating the nitrous compound necessary to effect the combination with ethyl

by acting on sodium nitrite with sulphuric acid in the presence of alcohol, the violence of the reaction being controlled by diluting both the sulphuric acid and the alcohol with water, and by using an aqueous solution of the nitrite. A very thorough means of refrigeration had to be used, on account of the extreme volatility of the distillate, and because evolution of ethyl nitrite commenced before all the sulphuric acid was added and without the use of any other heat than that generated by the chemical reaction. Heat was not applied until the reaction became slower, and then only very moderately and capable of being instantly withdrawn if necessary. The advantages of this process are that the production of aldehyde and acetic ether is avoided, through the absence of nitric acid, and pure ethyl nitrite is easily obtained. Sodium nitrite can be procured of standard purity, although the impurities in the commercial salt do not affect the character of the ethyl nitrite. The use of alkaline nitrites in making ethyl nitrite is not new, as both potassium and sodium nitrites have been employed, Feldhaus, Dunstan, Dymond,² and others having published processes; Frerichs of St. Louis, used the method on a large scale, and C. O. Curtman and E. L. Patch of Boston, also recommended its employment. See *Am. Drug.*, 1893, p. 171. An improvement was made in the U. S. P. (8th Rev.) process and in the cold processes pre-

¹ *Ethyl Nitrite. Expeditious Method of Preparing the Pure Ether.*—Dunstan and T. S. Dymond find the following method to be admirably adapted to the production of pure nitrous ether in the nearly theoretical quantity without the use of heat, the ether, in the absence of excess of acid, being easily separated without distillation. A solution is made by dissolving 34.5 grammes of sodium nitrite in water. The liquid is diluted to 120 Cc. and cooled below 0° C. by surrounding the vessel, which contains it with a mixture of ice and salt. The sodium nitrite of commerce contains from 95 to 98 per cent. of nitrite, and therefore a quantity corresponding to the pure salt must be taken. A slight excess of the salt does not interfere with the reaction. 13.5 Cc. of sulphuric acid is added to a cooled mixture of 32 Cc. of alcohol, with an equal volume of water; the liquid is then diluted to 120 Cc. and cooled below 0° C. This acid liquid is allowed to pass gradually through a thistle funnel with constant stirring to the bottom of the solution of sodium nitrite, contained in a long narrow glass vessel surrounded by ice and salt. The addition of the whole of the acid liquid occupies only a few minutes, and at its conclusion a pale-yellow layer of ethyl nitrite is found to be completely separated from the lower layer of solution of sodium sulphate, which is semi-solid from the separation of crystals of the salt. The ethyl nitrite so formed contains only traces of alcohol and water, the first being removed by agitation with cold water, the second by digestion with recently ignited anhydrous potassium carbonate. The yield is from 30 to 35 grammes; the calculated yield is 37.5. It cannot be preserved under ordinary conditions without decomposition, but if kept in contact with fragments of anhydrous potassium carbonate in a closely stoppered bottle it may be kept for a long time without change. It boils at 17.5° C., and possesses at 0° C. the sp. gr. 0.917–0.920 (water at 0° C. = 1). Analysis proves it to be nearly absolutely pure ethyl nitrite. The authors recommend for medicinal use a 2-per cent. solution of ethyl nitrite in absolute alcohol. Its stability might be increased by the addition of 5 per cent. of glycerin; but even this is prone to change, though not so much as the solution in absolute alcohol, simply while the solution in rectified spirit changes to a still greater extent. The solution intended to be administered should not be diluted with water until just before it is to be taken. (*P. J.*, 1888, 861–863.)

² R. F. Fairthorne prepared Spirit of Nitrous Ether without the use of a retort or still. (*A. J. P.*, 1880, p. 7; see also method by Emlen Painter, *Proc. A. Ph. A.*, 1884–1886.)

viously proposed by reversing the order of mixing the liquids in the flask; in the former pharmacopœial process the acid solution was dropped slowly into the sodium nitrite solution and alcohol; this caused some loss of ethyl nitrite with evolution of nitrogen tetroxide, on the other hand in the present official cold process if carefully conducted with sufficient refrigeration, the production of ethyl nitrite takes place uniformly and slowly with very little loss. The great advantage, however, in this process consists in the avoidance of distillation and use of heat in preparing a very volatile product.

The present British formula rejects the sodium nitrite process, but introduces under *Liquor Ethyl Nitritis* (see p. 711) a solution made by decomposing sodium nitrite in the presence of alcohol, and diluting the ethyl nitrite produced, with alcohol containing a little glycerin. It is unfortunate that both preparations were not made of the same strength, the solution containing 3 per cent., the spirit only 2 per cent., of ethyl nitrite; the solution contains no aldehyde, but the spirit is permitted to contain aldehyde and other substances.

Theory of the Production of Nitrous Ether, etc.—The reaction in the U. S. P. (8th Rev.) process may be expressed as follows:

Alcohol, sodium nitrite, and sulphuric acid when brought in contact yield ethyl nitrite, sodium sulphate, and water. The nitric acid process may be explained as follows. One molecule of nitric acid, by reacting with one molecule of alcohol, forms one molecule of nitrous acid, one molecule of *aldehyde*, and one molecule of water: thus,

The nitrous acid, as soon as formed, reacts with a second molecule of alcohol, so as to form one molecule of nitrous ether or ethyl nitrite, with separation of one molecule of water, according to the reaction:

In the process of the British Pharmacopœia the nitric acid is converted into nitrous acid by the reducing action of metallic copper and sulphuric acid, the reaction being:

The nitrous acid now reacts with the alcohol as in the previous reaction, so as to produce the nitrous ether. The object of using the sulphuric acid is to economize the nitric acid.

Properties of Ethyl Nitrite.—*Pure* ethyl nitrite is pale yellow, has the odor of apples and Hungary wine, boils at 18° C. (64.4° F.), and has the sp. gr. 0.900 at 15.5° C. The density of its vapor is 2.627. Litmus is not affected by it. When it is mixed with an alcoholic solution of potassium hydroxide, potassium hyponitrite and alcohol are formed, without producing a brown color, showing the absence of

aldehyde. It is soluble in 48 parts of water, and in all proportions in alcohol or rectified spirit. It is highly inflammable, and burns with a white flame without residue. The impure ether, as formerly obtained by the Edinburgh and Dublin processes for subsequent dilution to form sweet spirit of nitre, boiled at 21.1° C. (70° F.), and had the density of 0.886 at 4.4° C. (40° F.). The specific gravity assigned to it by the Edinburgh College was 0.899. Mixed with an alcoholic solution of potassium hydroxide, it became dark brown, with production of *aldehyde resin*. This discoloration showed the presence of aldehyde. When kept, it became acid in a short time, as shown by litmus, and nitric oxide was given off, which often caused the bursting of the bottle. Its tendency to become acid was rendered greater by the action of the air, and depended on the absorption of oxygen by the aldehyde, which thereby became acetic acid. Harvey of Leeds, has suggested the use of pure crystals of potassium bicarbonate in a bottle in order to prevent the development of an acid reaction. J. C. Rademacher has found that the crystals after a time are partially converted into a nitrate. (*A. J. P.*, xlii. 106.) These facts evince the propriety of preserving this ether in small, strong bottles, kept full and in a cool place. Nitrous ether is formed by the combination of nitrous acid with the radical ethyl, and its formula is $\text{C}_2\text{H}_5\text{NO}_2$. It was, therefore, improperly called *nitric ether*. Considered as a salt, its proper name is *ethyl nitrite*. In its pure and concentrated state it is never used in medicine. (See *Liquor Ethyl Nitritis*, p. 711.)

Properties of Spirit of Nitrous Ether.—This is “a clear, mobile, volatile, and inflammable liquid of a pale yellowish or faintly greenish-yellow tint, having a fragrant, ethereal, and pungent odor free from acidity, and a sharp, burning taste. Specific gravity: about 0.823 at 25° C. (77° F.). When freshly prepared, or even after being kept for some time with but little exposure to light and air, it is neutral to litmus paper. When long kept, or after having been freely exposed to air and light, it acquires an acid reaction, but it should not effervesce when a crystal of potassium bicarbonate is dropped into it.” *U. S.* “A limpid liquid, having a very faint yellowish tinge, inflammable, of a peculiar penetrating apple-like odor, and a characteristic taste. When Spirit of Nitrous Ether is carefully poured on an acidulated strong solution of *ferrous sulphate* contained in a test-tube, a deep olive-brown coloration is produced at the surface of contact of the two liquids, widening as the tube is gently shaken. 10 cubic centimetres, mixed with 5 cubic centimetres of the *volumetric solution of sodium hydroxide* and 5 cubic centimetres of *water*, should assume a yellow color, which should not become brown on standing 12 hours (limit of aldehyde). It should not effervesce, or only very feebly, when shaken with *sodium bicarbonate* (limit of acid).” *Br.* It keeps well in

half-pint bottles, securely stopped with waxed glass stoppers, and covered with dark paper, as Squibb proved by examining some bottles thus put up, after the lapse of two years. When exposed it is apt to become acid with age. Sweet spirit of nitre mixes with water and alcohol in all proportions. It is very inflammable, and burns with a whitish flame. The sp. gr. of the British official spirit of nitrous ether is 0.838 to 0.842 at 15° C. (59° F.).

Impurities and Tests.—Spirit of nitrous ether, when made by the nitric acid process, is never quite free from aldehyde, and, if the distillation be too long continued, it is prone to contain a good deal of this substance, which afterwards becomes acetic acid by absorbing oxygen. The change goes on rapidly if the preparation be insecurely kept. Aldehyde, if in considerable proportion, may be detected by its imparting a pungent odor and an acrid flavor, and by the spirit assuming a brown tint on adding a weak solution of potassium hydroxide, owing to the formation of aldehyde resin (see official test, page 1169). Another test for aldehyde, though less reliable, is the addition of an equal volume of sulphuric acid to the sweet spirit of nitre. If the sample be good, the change of color will be slight, and the mixture will be considerably viscid; if it contain much aldehyde, it will become dark-colored. If water or spirit be present in undue proportion, the viscosity will be less. (Phillips.) Acetic acid, as well as other acids (usually nitrogen acids) that may happen to be present, may be discovered by the taste, by their acting on litmus strongly, and by their decomposing the alkaline carbonates or bicarbonates with effervescence. Nitrogen acids are known by their coloring blue a piece of paper previously dipped into tincture of guaiac. These acids operate injuriously by their chemical reactions with other substances, when spirit of nitre is prescribed in mixtures. Thus, they liberate iodine from potassium iodide, gradually decolorize compound infusion of rose, and in the compound mixture of iron hasten the conversion of ferrous oxide into ferric oxide. To obviate these effects, Harvey of Leeds, makes sweet spirit of nitre standing on crystals of potassium bicarbonate, and states that, if the preparation be of full strength, no appreciable portion of the alkali will be dissolved. (*P. J.*, Jan. 1842.) When acid sweet spirit of nitre is rectified from calcined magnesia, it becomes acid again in a short time, but, according to Klauer, when rectified from neutral potassium tartrate it continues unchanged for months. A deep olive color with ferrous sulphate shows the presence of a nitrogen oxide or acid.

According to Bastick, sweet spirit of nitre contains about one-fifth of one per cent. of anhydrous hydrocyanic acid, when made from nitrous ether formed by acting upon alcohol with nitrous acid evolved by the action of starch on nitric acid, according to the process of

Liebig. In making sweet spirit of nitre on a large scale, Squibb found that hydrocyanic acid vapors were produced if the heat happened to rise too high, and the ether ceased to be formed. Schoor and G. B. Schmidt found that, after a careful distillation, hydrocyanic acid could be detected in the residue left in the retort to the amount of 0.977 per cent., while the distillate contained but an insignificant trace. (*Ph. Ztg.*, No. 37; *N. R.*, Sept. 1880.)

Alcohol and water are often fraudulently added to sweet spirit of nitre. These additions are difficult to detect. The official tests are as follows: "If a test-tube be half filled with the Spirit, and put into a water-bath heated to 65° C. (149° F.) until it has acquired this temperature, the Spirit should boil distinctly upon the addition of a few small pieces of broken glass. If 10 Cc. of the Spirit be mixed with 5 Cc. of potassium hydroxide T.S., previously diluted with 5 Cc. of water, the mixture will assume a yellow color which should not turn decidedly brown within twelve hours (limit of aldehyde)." *U. S.* When in undue proportion, alcohol and water may be detected in the British preparation, in a rough way, by agitating it with twice its volume of a saturated solution of calcium chloride. Specific gravity is no criterion of the quality of the preparation as obtained by any formula. The addition of water will raise its density, and the same effect will be produced by adding ethyl nitrite. A high density, in connection with deficient ethereal qualities, would of course indicate free acids, or an excess of water, or both. A specific gravity lower than the *U. S.* and *Br.* standard would show the presence of alcohol either stronger than it should be or in too large a proportion. The fraudulent dilution of sweet spirit of nitre with alcohol and water is a great evil, considering its extensive use and its valuable remedial properties. Water is injurious not merely as a diluent but also as the most efficient promoter of chemical changes. In commerce this valuable medicine is usually found variously diluted with twice, thrice, and even four times its weight of alcohol and water. In this way its ether strength is greatly reduced. Squibb examined six samples of sweet spirit of nitre, five of which were obtained from reliable wholesale druggists; of these one sample contained 3.16 per cent. of nitrous ether, four between one and two per cent., and one under one per cent., while a standard preparation, made according to the *U. S. Pharmacopœia*, contained at least 4.3 per cent. The addition of glycerin to spirit of nitrous ether has been highly recommended as a preservative.

Uses.—Spirit of nitrous ether is diaphoretic, diuretic, and antispasmodic. It is deservedly much esteemed as a medicine, and is extensively employed in febrile affections, either alone or in conjunction with tartar emetic, for the purpose of promoting the secretions, especially those of sweat and urine. It is especially selected in cases in which the tendency is asthenic.

On account of its action upon the kidneys, it is often conjoined with other diuretics, such as squill, digitalis, potassium acetate, nitre, etc., for the purpose of promoting their action in dropsical complaints.

The inhalation of sweet spirit of nitre produces acceleration of the pulse, with a peculiar leaden purple color of the lips, mouth, and finger-tips, followed by flushing of the face, extreme giddiness, nausea, muscular debility, and violent headache, excessively rapid irregular pulse, and dyspnoea. These symptoms undoubtedly depend in great part upon the presence of the ethyl nitrite, which action is without doubt like that of the other nitrites, being simply somewhat less prompt and fugacious than that of amyl nitrite, because the ethyl compound is less volatile, and therefore less rapidly absorbed and eliminated.

Dose, one-half to one fluidrachm (1.8 to 3.75 Cc.).

Off. Prep.—Mistura Glycyrrhizæ Composita, U. S.

SPIRITUS AMMONIÆ. U. S.

SPIRIT OF AMMONIA

(spîr'î-tûs æm-mō'nî-æ)

"An alcoholic solution of Ammonia [$\text{NH}_3 = 16.93$] containing ten percent., by weight, of the gas. This solution deteriorates on keeping, and should be tested frequently. It must not be dispensed for medicinal purposes if it contains less than 10 percent. of gaseous Ammonia." U. S.

Liquor Ammonii Caustici Spirituosus; Spiritus Ammoniaci Caustici Dzondil; Ammoniated Alcohol; Alcoolé d'Ammoniaque, Liqueur d'Ammoniaque vineuse, *Fr.*; Weingeistige Ammoniakflüssigkeit, Wein-geistiges Ammoniak, *G.*

* "Stronger Ammonia Water, *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims]; Alcohol, recently distilled, and, after distillation, kept in glass vessels, *a sufficient quantity*. Pour the Stronger Ammonia Water into a flask provided with a safety funnel and connected, by means of a glass condenser, with a well-cooled receiver containing *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Alcohol, the delivery tube of the condenser reaching nearly to the bottom of the receiver. Heat the flask carefully, and very gradually, to a temperature not exceeding 60°C . (140°F .), and maintain it at that temperature until Ammonia ceases to be evolved. Then disconnect the receiver, and, having ascertained the strength of a portion of the contents by the method of assay given below, add enough Alcohol to make the product contain *ten percent.*, by weight, of Ammonia gas. Keep the Spirit in glass-stoppered bottles, in a cool place." U. S.

Spirit of ammonia is now official in the U. S. Pharmacopœia only, the British Pharmacopœia not having adopted it. It is a solution of caustic ammonia in alcohol. As prepared by the U. S. process of 1850, the ammoniacal gas

was received in the alcohol and condensed by it; and the proportions of the ingredients were so adjusted as to give a preparation containing between 10 and 11 per cent. of ammonia, and capable of saturating about 30 per cent. of official sulphuric acid. Accordingly it agreed in ammoniacal strength, as it was intended it should do, with the U. S. Liquor Ammonia. Its sp. gr. was 0.831, or thereabouts. But in the official process of 1870 the materials for the generation of ammonia were mixed with a large proportion of water, the vapor of which came over to some extent with the gas and was condensed along with it. The resulting spirit was, therefore, somewhat diluted with water, and to an indefinite extent, so that the preparation had no precise sp. gr.; and, though the whole amount obtained contained all the ammonia generated, no accurate criterion of its relative strength could be made. This fault has been remedied in the present official process by substituting stronger water of ammonia for the ammonium chloride, water, and lime, and not permitting the temperature to rise above 60°C . (140°F). In addition to this, the amount of ammonia present is determined by volumetric assay, and it contains the same quantity of ammonia that is present in ammonia water, — *i.e.*, 10 per cent. Alcohol which has been kept in the cask for a long time will be discolored when the gaseous ammonia is passed into it.

Properties.—The spirit of ammonia, formerly called *ammoniated alcohol*, is "a colorless liquid, having a strong odor of ammonia, and a specific gravity of about 0.808 at 25°C . (77°F). When diluted with water, it should respond to the tests for identity and purity given under *Aqua Ammonia*." U. S.

Assay.—"Introduce into a weighing bottle about 2 Cc. of the Spirit, weigh accurately, dilute with 50 Cc. of distilled water, and titrate with half-normal sulphuric acid V.S., using litmus T.S. as indicator. Multiply the number of Cc. of half-normal sulphuric acid V.S. consumed, by 0.008465, and this product by 100, and divide by the weight in grammes of the Spirit taken to obtain the percentage of ammonia gas." U. S. When good, it does not effervesce with diluted hydrochloric acid; but if old, or carelessly kept, it is apt to be partially carbonated, as shown by this test. It, however, absorbs carbon dioxide more slowly than does ammonia water.

Uses.—Spirit of ammonia is stimulant and antispasmodic, and is given in *hysteria*, *flatulent colic*, and *nervous debility*. It is, however, little used internally, the aromatic spirit, which is pleasanter and has similar properties, being preferred. Spirit of ammonia dissolves resins, gum-resins, camphor, and the volatile oils, and is a very convenient addition to spirituous liniments intended to produce a rubefacient effect. Not more than one part of the spirit should, as a rule, be added to six or eight parts, by measure, of the liniment. It enters into no official preparation.

Dose, ten to thirty minims (0.6 to 1.8 Cc.) in a wineglassful (60 Cc.) of water.

SPIRITUS AMMONIÆ AROMATICUS.

U. S., Br.

AROMATIC SPIRIT OF AMMONIA

(spîr'î-tūs am-mō'nî-æ ār-q-măt'î-cūs)

Spiritus Ammoniae Compositus; Spirit of Sal Volatile; Alcoolat ammoniacal aromatique, *Fr. Cod.*; Aromatischer Ammoniakgeist, *G.*

* "Ammonium Carbonate, in translucent pieces, *thirty-four grammes* [or 1 ounce av., 87 grains]; Ammonia Water, *ninety cubic centimeters* [or 3 fluidounces, 21 minims]; Oil of Lemon, *ten cubic centimeters* [or 162 minims]; Oil of Lavender Flowers, *one cubic centimeter* [or 16 minims]; Oil of Myristica, *one cubic centimeter* [or 16 minims]; Alcohol, *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims]; Distilled Water, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. To the Ammonia Water, contained in a flask, add *one hundred and forty cubic centimeters* [or 4 fluidounces, 352 minims] of Distilled Water, and afterwards the Ammonium Carbonate reduced to a moderately fine powder. Close the flask and agitate the contents until the Ammonium Carbonate is dissolved and allow it to stand for twelve hours. Introduce the Alcohol into a graduated bottle of suitable capacity, add first the Oils, then gradually the solution of Ammonium Carbonate, and afterwards enough Distilled Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Set the liquid aside during twenty-four hours in a cool place, occasionally agitating, then filter it through paper, in a well-covered funnel. Keep the product in glass-stoppered bottles, in a cool place." *U. S.*

"Ammonium Carbonate, *4 ounces* (Imperial) or 100 grammes; Strong Solution of Ammonia, *8 fl. ounces* (Imp. meas.) or 200 cubic centimetres; Oil of Nutmeg, *4½ fl. drachms* (Imp. meas.) or 14.1 cubic centimetres; Oil of Lemon, *6½ fl. drachms* (Imp. meas.) or 20.3 cubic centimetres; Alcohol (90 per cent.), *6 pints* (Imp. meas.) or 3000 cubic centimetres; Distilled Water, *3 pints* (Imp. meas.) or 1500 cubic centimetres. Place the Oil of Lemon, Oil of Nutmeg, and Alcohol with the Distilled Water in a retort; distil *seven pints* (Imp. meas.) or three thousand five hundred cubic centimetres; then distil and separately collect an additional *nine fluid ounces* (Imp. meas.) or two hundred and twenty-five cubic centimetres. Place the latter, together with the Ammonium Carbonate and the Strong Solution of Ammonia, in a bottle holding rather more than *a pint* (Imp. meas.) or rather more than half a litre; securely cork the bottle and gently warm it in a water-bath to 140° F. (60° C.), shaking from time to time until all the salt has dissolved. Filter

the resulting solution when cold through cotton wool, and gradually mix the filtrate with the portion first distilled." *Br.*

In both of these formulas ammonium carbonate and uncombined ammonia are used; but they differ in the relative proportion of the materials and the mode of conducting the process. The U. S. spirit is a mere solution of the ingredients in alcohol diluted with a small proportion of water, while the British contains so much of the ingredients as may rise in distillation and be condensed with the seven pints of spirit that result. The strength of the former is definite, that of the latter more or less indefinite, as a portion of the materials must be left behind. The advantage arising from distillation, however, the avoidance of discoloration, is one which is well worth considering, although the spirit will always grow darker with age. The present preparation differs from that formerly official in the substitution of oil of myristica for oil of pimenta, it having been shown that oil of pimenta increased the tendency of the spirit to darken. Commercial oil of myristica frequently has a terebinthinate odor. Much care is needed to select for this preparation volatile oils that are fresh and of good quality. The translucent official ammonium carbonate, which is a mixture of bicarbonate and carbamate, does not dissolve in alcohol; the bicarbonate precipitates, and the carbamate dissolves. The object of the addition of free ammonia in the official process is to convert the insoluble bicarbonate into the carbamate, and it is directed that these shall be allowed to stand during *twelve hours* while this change is taking place. The effloresced ammonium carbonate of commerce having parted with some of its ammonia is a bicarbonate; hence when it is used, unless more than the official proportion of the ammonia water be added, some of the ammonium salt will remain in the precipitate as ammonium bicarbonate.

The difficulty of precipitation which so many pharmacists complain of is thus explained. It is a useful precaution to permit the ammonium carbonate and ammonia water to remain in contact for twelve hours before diluting with the other ingredients; this will secure the entire conversion of the bicarbonate, and obviate the precipitation above noted. In addition to this, it is officially directed to set the mixed liquid aside, for twenty-four hours, before final filtration. It is officially described as "a nearly colorless liquid when freshly prepared, but gradually acquiring a somewhat darker tint. It has the pungent odor and taste of ammonia. Specific gravity; about 0.900 at 25° C. (77° F.)." *U. S.* "A transparent liquid having a pungent ammoniacal odor and flavor; nearly colorless when first prepared, but liable to darken slightly. Specific gravity 0.888 to 0.893. 20 cubic centimetres require for neutralization 25.5 cubic centimetres of the volumetric solution of sulphuric acid, corresponding to about 2.4 per cent. of ammonia (NH₃), or 2.16 grammes in 100

cubic centimetres. 20 cubic centimetres, after the addition of 16 cubic centimetres of *solution of barium chloride*, should yield a precipitate which becomes more copious on heating to 160° F. (71° C.), and after filtering, the filtrate should yield a further precipitate when more of the reagent is added and the liquid is again heated." *Br.*

Uses.—Aromatic spirit of ammonia is much more largely used than the simple spirit of ammonia on account of its grateful taste and odor. It is advantageously employed as a stimulant antacid in *sick headache*.

Dose, thirty minims to a fluidrachm (1.8 to 3.75 Cc.), sufficiently diluted.

Off. Prep.—Mistura Sennæ Composita, *Br.*; Tinctura Guaiaci Ammoniata, *U. S.*; Tinctura Valerianæ Ammoniata, *U. S.*

SPIRITUS AMMONIÆ FŒTIDUS. Br.

FETID SPIRIT OF AMMONIA

(spîr'î-tûs æm-mō'nî-æ fœt'î-dûs)

Alcoolat ammoniacal fétide, Essence anthystérique, *Fr.*; Ammoniakallischer Stinkasantgeist, *G.*

"Asafetida, 1½ ounces (Imperial) or 75 grammes; Strong Solution of Ammonia, 2 fl. ounces (Imp. meas.) or 100 cubic centimetres; Alcohol (90 per cent.), a sufficient quantity. Break the Asafetida into small pieces, and macerate it in a closed vessel in fifteen fluid ounces (Imp. meas.) or seven hundred and fifty cubic centimetres of the Alcohol for twenty-four hours; distil until alcoholic vapors cease to be condensed; mix the distillate with the Strong Solution of Ammonia, and add sufficient Alcohol to make one pint (Imp. meas.) or one thousand cubic centimetres." *Br.*

This is an alcoholic solution of the volatile oil of asafetida mixed with strong water of ammonia, and is an energetic nervous stimulant and antacid, adapted to certain hysterical conditions associated with gastric weakness and acidity. It is one of the preparations formerly recognized by the British Colleges, and reinstated after having been dropped from the first British Pharmacopœia. "25 cubic centimetres should require for neutralization at least 42.5 cubic centimetres of the volumetric solution of sulphuric acid, corresponding to at least 2.88 grammes of ammonia (NH₃) in 100 cubic centimetres." *Br.*

Dose, thirty minims to a fluidrachm (1.8 to 3.75 Cc.), to be largely diluted when administered.

SPIRITUS AMYGDALÆ AMARÆ. U. S.

SPIRIT OF BITTER ALMOND [Essence of Bitter Almond]

(spîr'î-tûs æ-mÿg'da-læ æ-mā-ræ)

Alcoolé d'essence amande amère, *Fr.*; Bittermandelgeist, *G.*

* "Oil of Bitter Almond, ten cubic centimeters [or 162 minims]; Alcohol, eight hundred

cubic centimeters [or 27 fluidounces, 24 minims]; Distilled Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Dissolve the Oil in the Alcohol, and add enough Distilled Water to make the product measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This was a new official spirit in the U. S. P. 1890; it is employed solely for flavoring purposes, and should always be used with care. The official oil of bitter almond now requires the presence of a trace of hydrocyanic acid, and hence the official spirit, containing 1 per cent. of oil, would show a slight trace. It would be safer to use for the spirit an oil free from hydrocyanic acid. A few drops only should be added to those substances which require a flavor.

Dose, from two to eight minims (0.12 to 0.5 Cc.).

Off. Prep.—Syrupus Amygdalæ, *U. S.*

SPIRITUS ANISI. U. S., Br.

SPIRIT OF ANISE

(spîr'î-tûs æ-nî'sî)

Essence of Anise; Teinture d'essence d'anis vert, *Fr. Cod.*; Anisgeist, *G.*

* "Oil of Anise, one hundred cubic centimeters [or 3 fluidounces, 183 minims]; Alcohol, nine hundred cubic centimeters [or 30 fluidounces, 208 minims], to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix them." *U. S.* "Oil of Anise, 1 fl. ounce (Imperial measure) or 50 cubic centimetres; Alcohol (90 per cent.), a sufficient quantity. To the Oil of Anise add enough of the Alcohol to form ten fluid ounces (Imp. meas.) or five hundred cubic centimetres of the Spirit of Anise. This Spirit of Anise contains half the proportion of Oil of Anise present in the Essence of Anise of the British Pharmacopœia of 1885," *Br.*, and is now of the same strength as the U. S. spirit.

Dose, as a stomachic and carminative, from one to two fluidrachms (3.75 to 7.5 Cc.), properly diluted.

SPIRITUS ARMORACIÆ COMPOSITUS.

Br.

COMPOUND SPIRIT OF HORSE RADISH

(spîr'î-tûs ær-mō-rā'ci-æ cōm-pōs'î-tûs)

Esprit (alcoolat) de Raifort composée, Alcoolat antiscorbutique, *Fr.*; Zusammengesetzter Meerrettiggeist, *G.*

"Horseradish Root, scraped, 5 ounces (Imperial) or 125 grammes; Dried Bitter-Orange Peel, well bruised, 5 ounces (Imp.) or 125 grammes; Nutmeg, bruised, 55 grains or 3.15 grammes; Alcohol (90 per cent.), 14 pints

(Imp. meas.) or 625 cubic centimetres; Distilled Water, $1\frac{1}{2}$ pints (Imp. meas.) or 750 cubic centimetres. Mix, and distil *two pints* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This may be used advantageously as an addition to diuretic remedies, in *dropsy* attended with debility, especially in the case of drunkards.

Dose, from one to four fluidrachms (3.75 to 15 Cc.).

SPIRITUS AURANTII COMPOSITUS.

U. S.

COMPOUND SPIRIT OF ORANGE

(spîr'i-tûs au-rân'ti-i côm-pôs'i-tûs)

Teinture d'essence d'orange, *Fr. Cod.*; Esprit d'orange composée, *Fr.*; Zusammengesetzter Orangegelst, *G.*

* "Oil of Orange Peel, *two hundred cubic centimeters* [or 6 fluidounces, 366 minims]; Oil of Lemon, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Oil of Coriander, *twenty cubic centimeters* [or 325 minims]; Oil of Anise, *five cubic centimeters* [or 81 minims]; Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Mix them. Keep the product in completely filled, well-stoppered bottles, in a cool and dark place." *U. S.*

This compound spirit has been introduced for the purpose of producing the orange flavor in making the official Elixir Aromaticum (page 433). It will be found by physicians to be a useful and fragrant addition to prescriptions.

Off. Prep.—Elixir Aromaticum, *U. S.*; Fluidextractum Rhamni Purshianæ Aromaticum, *U. S.*

SPIRITUS CAJUPUTI. Br.

SPIRIT OF CAJUPUT

(spîr'i-tûs cāj-ū-pū'ti)

Teinture (alcoolé) d'essence de Cajuput, *Alcoolé d'essence de Cajuput, Fr.*; Cajuputgeist, *G.*

"Oil of Cajuput, 1 *fl. ounce* (Imperial measure) or 50 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity*. To the Oil of Cajuput add enough of the Alcohol to form *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Spirit of Cajuput." *Br.*

For an account of the medicinal properties and uses of oil of cajuput, of which this is simply an alcoholic solution, see *Oleum Cajuputi*. "This Spirit of Cajuput contains five times the proportion of Oil of Cajuput present in the Spirit of Cajuput of the British Pharmacopœia of 1855." *Br.*

Dose, from five to twenty minims (0.3 to 1.3 Cc.), properly diluted.

SPIRITUS CAMPHORÆ. U. S., Br.

SPIRIT OF CAMPHOR

(spîr'i-tûs cām'phō-ræ)

Tinctura Camphoræ, *U. S.* 1850; Tincture of Camphor; Alcohol Camphoratus; Teinture de camphre concentrée, *Fr. Cod.*; Esprit de Camphre, *Alcool camphré, Fr.*; Spiritus Camphoratus, *P. G.*; Kampher-spiritus, *G.*

* "Camphor, *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Dissolve the Camphor in *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol, filter through paper, and pass enough Alcohol through the filter to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]." *U. S.*

"Camphor, 1 *ounce* (Imperial) or 50 grammes; Alcohol (90 per cent.), *a sufficient quantity*. To the Camphor add enough of the Alcohol to form *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Spirit of Camphor." *Br.*

The present official spirit differs from that of 1880 in being made from alcohol *without dilution with water*; this change was recommended in the preceding edition of this commentary. The addition of water to the solution was by no means a practical improvement, in view of the extensive employment of the preparation in liniments containing chloroform, oils, etc., in which, of course, it was frequently immiscible without producing turbidity. For a method of assay of spirit of camphor see *Ph. Centralt.*, 1901, 472. Spirit of camphor is an excellent preparation, much used locally in liniments and internally in affections of the alimentary canal and as an antispasmodic. Dilution with water precipitates the camphor, but when as in many cases it is desired to combine it with aqueous preparations, by dropping it into brandy or whisky and then adding water an eligible preparation is obtained; or the spirit of camphor may be dropped upon sugar and then mixed with water.

Dose, from ten to thirty minims (0.6 to 1.8 Cc.).

SPIRITUS CHLOROFORMI. U. S., Br.

SPIRIT OF CHLOROFORM

(spîr'i-tûs chlō-rō-fōr'mi)

Chloric Ether, Spirit of Chloric Ether, *Br.*; Alcoolé de Chloroforme, *Fr.*; Chloroformspiritus, *G.*

* "Chloroform, *sixty cubic centimeters* [or 2 fluidounces, 14 minims]; Alcohol, *nine hundred and forty cubic centimeters* [or 31 fluidounces, 377 minims], to make *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Mix them." *U. S.*

"Chloroform, 1 fl. ounce (Imperial measure) or 50 cubic centimetres; Alcohol (90 per cent.), a sufficient quantity. To the Chloroform add enough of the Alcohol to form one pint (Imp. meas.) or one thousand cubic centimetres of the Spirit of Chloroform." *Br.*

The chloroform strength of this preparation does not differ very greatly from that of the spirit of chloroform which was official in the United States Pharmacopœia of 1880; the latter contained 10 per cent. of chloroform by weight, while the spirit now official contains 6 per cent. by volume, the seeming difference being due to the specific gravity of the chloroform. Chloric ether of the older works was a solution of variable strength of chloroform in alcohol, and was used as a general anæsthetic. The practice has, however, very properly been abandoned, and the spirit of chloroform is now used as an internal remedy, especially in cases of gastro intestinal spasm or pain, in which it acts as a local agent. The official elixir of orange is an agreeable vehicle for its administration.

Dose, from ten to sixty minims (0.6 to 3.75 Cc.).¹

SPIRITUS CINNAMOMI. U. S., *Br.*

SPIRIT OF CINNAMON

(spîr'î-tûs cîn-namô'mî)

Teinture (alcoolé) d'essence de Cannelle, *Esprit de Cannelle, Fr.; Zimmtspiritus, G.; Spirito di cannella, It.*

*"Oil of Cinnamon, one hundred cubic centimeters [or 3 fluidounces, 183 minims]; Alcohol, nine hundred cubic centimeters [or 30 fluidounces, 208 minims], to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix them." *U. S.*

"Oil of Cinnamon, 1 fl. ounce (Imperial measure) or 50 cubic centimetres; Alcohol (90 per cent.), a sufficient quantity. To the Oil of Cinnamon add enough of the Alcohol to form ten fluid ounces (Imp. meas.) or five hundred cubic centimetres of the Spirit of Cinnamon." *Br.*

The spirit of cinnamon is an agreeable aromatic cordial. It contains five times the

proportion of oil of cinnamon present in the spirit of cinnamon of the British Pharmacopœia of 1885.

Dose, from five to twenty minims (0.3 to 1.3 Cc.) in water.

Off. Prep.—Acidum Sulphuricum Aromaticum, *Br.*; Syrupus Rhei, *U. S.*

SPIRITUS FRUMENTI. U. S.

WHISKY

(spîr'î-tûs frû-mên'ti)

"An alcoholic liquid obtained by the distillation of the fermented mash of grain—such as Indian corn, rye, wheat, and barley, or their mixtures." *U. S.*

Eau de Vie de grain, Fr.; Kornbranntwein, G.

The term *whisky* is said to have been first applied to the spirit obtained from barley in the Highlands of Scotland, and to signify water in the language of the people of that region. (*Rees's Cyclopædia.*) In the strict sense of the word, as at present understood, and as officially defined, it belongs to the distilled spirit from different grains, including Indian corn, wheat, rye, and barley. The whisky of this country is generally made from corn or rye. The term, however, is sometimes extended to other forms of ardent spirit, and that resulting from the distillation of cider is frequently, although incorrectly, designated as *apple whisky*.

In the preparation of whisky, the infusion of rye or other grains is first made to undergo fermentation, by which the saccharine matter and indirectly the starch are converted into alcohol. In this state the liquid is called the *mash*. This is submitted to distillation, and the product is denominated *low wines*. By a second distillation it becomes purer and stronger, and now takes the name of raw corn spirit or whisky. Sometimes, we are informed, it is submitted to a third distillation, in order still further to purify it. By time certain chemical changes take place by which the natural impurities contained in the liquor are destroyed, and the whisky becomes mellow, losing the disagreeable odor and taste which it is apt to have when first distilled. It is generally believed that these changes involve the conversion of the aldehydic constituents of the raw spirit into acids which unite with the higher alcohols of the fusel oil to form esters which give the improved taste and mellowness to an aged whisky.

There are volatile principles naturally existing in the grains, which accompany the liquor in all its changes and give their characteristic flavor to the resulting spirit. These can scarcely be considered as impurities. But there are others, produced during the process of fermentation, which serve seriously to contaminate the product. Among these is *fusel*

¹ *Alcoholic Solution of Chloroform.*—A preparation for inhalation, composed of one-third pure chloroform and two-thirds nearly absolute alcohol, was recommended by Warren, under the name of *strong chloric ether*. Snow has since employed a similar mixture, using equal parts of chloroform and alcohol. The mixture, made in the proportion adopted by Snow, is commended by Robert as the best anæsthetic agent yet proposed. As the name chloric ether was originally applied by T. Thomson of Glasgow, to Dutch liquid (see page 329), it would be well to abandon the same appellation to designate chloroform, or its mixture with alcohol. Warren used his preparation in fifty cases with success, and considered it safer than chloroform, and more agreeable than ether, but there is no reason for supposing that it has especial value. The preparation sold in London and elsewhere under the name of "*chloric ether*" is a weak solution of chloroform of variable quality, containing at most but 16 or 18 per cent. of chloroform, and sometimes not more than 5 or 6 per cent.

oil or grain oil (amyl alcohol), which is offensive both to the smell and to the taste, and from which it is very desirable that the spirit should be freed as far as possible. This is determined in an approximately quantitative way by shaking out with carbon tetrachloride, oxidizing the solution so obtained with chromic acid mixture, and then titrating the valeric and other acids obtained with decinormal barium hydroxide. Minute proportions of acetic and butyric acids are often present in whisky, and valeric acid has been detected. (*A. J. P.*, 1859, 573.)

Properties.—Whisky, when recently prepared, is colorless; one method of giving it color was to store it in sherry casks whereby flavor as well as a brownish-yellow color was acquired. At present it is almost always stored in oaken barrels, the inside of the staves of which have been charred. By remaining in such barrels for several years undisturbed it ages rapidly and acquires color from the caramelized "wood gum" of the barrels. Its taste and odor, when mellow by age, though peculiar, are not disagreeable. According to the U. S. P. (8th Rev.), whisky is "an amber-colored liquid, having a distinctive odor and taste, and a slightly acid reaction. Whisky should be at least four years old. Its specific gravity should not be more than 0.945, nor less than 0.924 at 15.6° C. (60° F.), corresponding, approximately, to an alcoholic strength of 37 to 47.5 percent. by weight, or 44 to 55 percent. by volume, of absolute alcohol (see PART III, Alcohol Tables). If 100 Cc. of Whisky be very slowly evaporated in a tared dish on a water-bath, the last portions volatilized should not have a harsh or disagreeable odor (absence of more than a trace of *fusel oil* from grain); and the residue, when dried at 100° C. (212° F.), should not weigh more than 0.5 Gm. This residue should have no sweet or distinctly spicy taste (absence of *added sugar, glycerin, and aromatic substances*), and it should almost completely dissolve in 10 Cc. of cold water, forming a solution which is colored not deeper than light green by a few drops of ferric chloride T.S. diluted with 10 volumes of water (absence of more than traces of *oak tannin* from casks). If 50 Cc. of Whisky be shaken vigorously in a stoppered flask with 25 Gm. of kaolin, and, after standing half an hour, be filtered, the color of the filtrate should not be much lighter than that of the Whisky before treatment. To render 100 Cc. of Whisky distinctly alkaline to litmus, not more than 1.2 Cc. of normal potassium hydroxide V.S. should be required (limit of *free acid*)." U. S.

Whisky is an excellent alcoholic stimulant, which differs therapeutically from brandy in its having less tendency to cause constipation. Owing to its cheapness and its customary purity, it is usually preferable to brandy as a medicinal agent. It is also used as an antiseptic for wounds and ulcers.

SPIRITUS GAULTHERIÆ. U. S.

SPIRIT OF GAULTHERIA [Spirit of Wintergreen]

(spîr'-tûs gaul-thér-i-æ)

Tincture (alcoolé) d'essence de Gaulthérie, *Fr.*; Bertheegelst, *G.*

* "Oil of Gaultheria, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Alcohol, *nine hundred and fifty cubic centimeters* [or 32 fluidounces, 59 minims], to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix them." U. S.

This spirit, which was made official for the first time in the U. S. P. 1880, is simply a solution of the oil of gaultheria in alcohol in the proportion of 5 per cent.; it has long been in use in many parts of our country, and authoritative recognition was needed. It is probably most largely used for imparting flavor to prescriptions.

Dose, from ten to twenty minims (0.6 to 1.3 Cc.).

SPIRITUS GLYCERYLIS NITRATIS.

U. S. (Br.)

SPIRIT OF GLYCERYL TRINITRATE, SPIRIT OF

NITROGLYCERIN [Spiritus Glonoinl,

Pharm. 1890, Spirit of Glonoin]

(spîr'-tûs glyç-ê-rÿ'lis ni-trá'tis)

"An alcoholic solution containing 1 percent., by weight, of Glyceryl Trinitrate [$C_3H_5(O.N.O_2)_3 = 225.44$]. Spirit of Nitroglycerin should be kept and transported in well-stoppered tin cans, and should be stored in a cool place, remote from lights or fire. Great care should be exercised in dispensing, handling, packing, transporting, and storing the Spirit, since a dangerous explosion may result if any considerable quantity of it be spilled, and the alcohol be partly or wholly lost by evaporation. If, through accident, it be spilled, a solution of potassium hydroxide should be at once poured over it, to effect decomposition." U. S.

Liquor Trinitrini, Br.: Solution of Trinitrin; Liquor Nitroglycerinl; Solution of Nitroglycerin; Liquor Glonoinl; Solution of Glonoin; Nitroglycerin-geist, Glycerintrinitratlösung, *G.*

"Trinitroglycerin of commerce, 17½ grains or 1 gramme; Alcohol (90 per cent.), a sufficient quantity. Dissolve the trinitroglycerin in sufficient of the Alcohol to produce *four fluid ounces* (Imp. meas.) or one hundred cubic centimetres of the Solution of Trinitrin." Br.

This official spirit was introduced into the U. S. P. 1890 with the view of furnishing an eligible mode of administering nitroglycerin.

The British Liquor Trinitrini is practically identical. Abundant precautions are included, which should on no account be neglected. The official description is as follows: "A clear, colorless liquid, having the odor and taste of alcohol. *Caution should be exercised in tasting*

it, since even a small quantity of it is liable to produce a violent headache. The same effect is produced when it is freely applied to the skin. It is neutral to litmus paper. Specific gravity: 0.814 to 0.820 at 25° C. (77° F.). On diluting 10 Cc. of the Spirit with 15 Cc. of water—both liquids, as well as the mixture, being brought to 15° C. (59° F.)—the liquid will exhibit at most a faint cloudiness, but the addition of a further portion of 5 Cc. of water should produce a white turbidity. If the specific gravity of the Spirit be higher than 0.830 at 25° C. (77° F.), or if 10 Cc. of it be rendered turbid by less than 10 Cc. of water, the Spirit should be rejected." *U. S.* "A clear and colorless liquid, neutral to test-papers. Specific gravity 0.840. A mixture of 10 cubic centimetres with an equal volume of water, cooled to 60° F. (15.5° C.), remains clear, but the further admixture of 1 cubic centimetre of water causes opacity (presence of a due amount of trinitroglycerin). On further diluting with water and setting the mixture aside, there is deposited a liquid of oily consistence, one drop of which, absorbed by paper and struck with a hammer on a hard surface, explodes. 110 minims contain 1 grain of trinitroglycerin; 100 cubic centimetres contain 1 gramme." *Br.* For a method of assaying this spirit, by Chas. Rice, see *Am. Drug.*, 1895, 6; also Nagelvoort's method, *A. J. P.*, 1894, 527. On account of the importance of nitroglycerin as a therapeutic agent, we append the following.

Nitroglycerin. Trinitrine. Glonoin. Glyceryl Trinitrate. ($C_3H_5(NO_3)_3$).—When glycerin is gradually added in small portions at a time to a mixture of one part of strong nitric acid and three to four parts of concentrated sulphuric acid, and at a temperature kept low by artificial refrigeration, it is converted into a bright yellow liquid, which has remarkable explosive properties and has received the name at the head of this article. Nitroglycerin was discovered in the year 1847 by Sobrero of Turin. It was afterwards made a subject of study by de Vrij of the Netherlands, Gladstone, and Kopp, but did not attract general attention until 1867, when Alfred Nobel, a Swedish engineer, suggested its use for explosive purposes. It is a yellow liquid (said to be colorless or slightly yellowish when pure); of a sp. gr. from 1.525 to 1.6; inodorous; of a sweet, pungent, aromatic taste; very slightly soluble in water, but readily soluble in ether, alcohol, and methylated spirit; not freezing above -15.5° C. (4° F.) when quite pure, according to J. R. Wagner, but, as it occurs in commerce, solidifying by continued exposure to a temperature of 8° C. (46.4° F.), and assuming the form of long needles, which it is dangerous to handle, as they explode violently when gently broken. In the liquid state the mere contact of flame does not inflame or explode it; but concussion, or touching it with a red-hot iron, explodes it with great

vehemence. Detonating mixtures, or exploding gunpowder, in its near vicinity, produce the same effect. By keeping, it undergoes partial decomposition, and in confined vessels the pressure of the accumulated gases which result is sometimes so great as to cause its explosion upon the slightest concussion. Its explosive force greatly exceeds that of gunpowder. According to Nobel, one measure of the fluid yields on explosion 10,384 measures of gas, while one measure of gunpowder yields only 800 measures. It has, therefore, been much employed in blasting rocks, in mining, quarrying, road making, etc., and its economical advantages have kept it in extensive use, notwithstanding the danger. From these facts the inference is evident that it should not be kept in large quantities, nor conveyed to any considerable distance; the most fearful consequences have followed a neglect of these precautions. Practical operators recommend that it should be made extemporaneously where wanted as an explosive agent.

Nitroglycerin is formed by the introduction of the nitro-group (NO_2) in place of the three replaceable hydrogen atoms of the glycerin formula, according to the reaction:

E. Kopp gives the following as his method of preparing nitroglycerin on the spot where it is needed. First, fuming nitric acid of the sp. gr. 1.51 to 1.53 is mixed with twice its weight of the strongest sulphuric acid. At the same time commercial glycerin, free from lead and lime, is evaporated in a pot to 30° or 31° Baumé, so that on cooling it shall have a syrupy consistence. Into 3300 grammes of the acid mixture, contained in a glass or porcelain capsule placed in a trough of cold water, 500 grammes of the prepared glycerin are slowly poured with constant stirring, great care being taken to prevent any sensible heating of the mixture. The whole is then to be left for five or ten minutes, after which the mixture is to be poured into five or six times its volume of cold water to which a rotatory motion has been given. The nitroglycerin precipitates rapidly in the form of a heavy liquid, which is separated by decantation, then washed with a little alkaline water which is decanted, and then put into bottles. In this state it still contains a little acid and water, but these do not interfere with its use as an explosive agent. Latterly it has also been prepared by mixing 3½ parts of sulphuric acid of 1.83 sp. gr. with 1 part of potassium nitrate, and cooling this, when potassium sulphate will crystallize out. The acid drained off from this is peculiarly adapted for the formation of nitroglycerin, which then takes place rapidly and without so much dangerous development of heat.

Uses.—The action of nitroglycerin upon the human system is that of the nitrites. It differs in its influence from amyl nitrite solely in that its effects are not quite so prompt and are

perceptible for a much longer time. The amount required to produce a sensible action is exceedingly small. Thus J. M. Merriek experienced distinct effects from one-fortieth of a drop, and Field has recorded a temporary loss of consciousness and other alarming symptoms as produced by about one-forty-fifth of a drop. In the case of B. Schuchardt (*A. J. P.*, 1867), as much as ten drops are affirmed to have been swallowed, with the production of giddiness, violent, throbbing headache, weariness, and a semi-unconsciousness lasting several hours. According to Louis Kolipinski (*Med. News*, 1890), two drachms of the ordinary solution of nitroglycerin have been recovered from without very serious symptoms (amount taken doubtful). For a case in which death was legally decided to have been criminally produced by the poison, see *J. P. C.*, xxvi. 356. The inhalation of the vapors of nitroglycerin produces the same symptoms, so that care is recommended in its manufacture. As nitroglycerin may be considered a glyceryl nitrate, its action as a nitrite appears at first remarkable. It has been shown, however, by Hay that during its alkaline decomposition it yields nascent nitrous acid, and it can scarcely be questioned that this acid is developed and acts upon the system.

Spirit of glonoin, or an equivalent solution of *nitroglycerin*, is very much used in *angina pectoris*, *asthma*, *convulsions*, and other diseases in which amyl nitrite is employed. (See *Amyl Nitris*.) As a *cardiac stimulant*, in collapse, poisoning by illuminating gas, and other conditions, it may be used either by the mouth or by subcutaneous injections.

Dose, of the spirit, from one to two minims (0.06 to 0.12 Cc.).

SPIRITUS JUNIPERI. U. S., Br.

SPIRIT OF JUNIPER

(spir'i-tūs jū-nīp'ē-rī)

Teinture d'essence de Genièvre, *Fr. Cod.*; Spiritus Juniperi, *P. G.*; Wachholderspiritus, *G.*

* "Oil of Juniper, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Alcohol, *nine hundred and fifty cubic centimeters* [or 32 fluidounces, 59 minims], to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix them." *U. S.*

"Oil of Juniper, 1 *fl. ounce* (Imperial measure) or 50 cubic centimetres; Alcohol (90 per cent.), a *sufficient quantity*. To the Oil of Juniper add enough of the Alcohol to form *one pint* (Imp. meas.) or one thousand cubic centimetres of the Spirit of Juniper. If the solution be not clear, agitate with a little *powdered talc*, and filter. This Spirit of Juniper contains two and a half times the proportion of Oil of Juniper present in the Spirit of Juniper of the British Pharmacopœia of 1885." *Br.* It is now uniform in strength with the U. S. preparation.

This spirit is used chiefly as an addition to diuretic infusions. It is about 33 per cent. stronger than the spirit official before 1890.

Dose, from thirty to sixty minims (1.8 to 3.75 Cc.).

Off. Prep.—Mistura Creosoti, *Br.*

SPIRITUS JUNIPERI COMPOSITUS.

U. S.

COMPOUND SPIRIT OF JUNIPER

(spir'i-tūs jū-nīp'ē-rī cōm-pōs'ī-tūs)

Teinture (alcoolé) d'essence de Genièvre composée, *Fr.*; Zusammengesetzter Wachholderspiritus, *G.*

* "Oil of Juniper, *eight cubic centimeters* [or 130 minims]; Oil of Caraway, *one cubic centimeter* [or 16 minims]; Oil of Fennel, *one cubic centimeter* [or 16 minims]; Alcohol, *fourteen hundred cubic centimeters* [or 47 fluidounces, 162 minims]; Water, a *sufficient quantity*, to make *two thousand cubic centimeters* [or 67 fluidounces, 301 minims]. Dissolve the Oils in the Alcohol, and gradually add enough Water to make the product measure *two thousand cubic centimeters* [or 67 fluidounces, 301 minims]." *U. S.*

This spirit is a useful addition to diuretic infusions and mixtures in debilitated cases of *dropsy*. It corresponds very closely to Holland gin.

Dose, from two to four fluidrachms (7.5 to 15 Cc.).

SPIRITUS LAVANDULÆ. U. S., Br.

SPIRIT OF LAVENDER

(spir'i-tūs lā-vān'dū-læ)

Teinture (alcoolé) d'essence de Lavande, *Fr.*; Spiritus Lavandulæ, *P. G.*; Lavandelspiritus, *G.*

* "Oil of Lavender Flowers, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Alcohol, *nine hundred and fifty cubic centimeters* [or 32 fluidounces, 59 minims], to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix them." *U. S.*

"Oil of Lavender, 1 *fl. ounce* (Imperial measure) or 50 cubic centimetres; Alcohol (90 per cent.), a *sufficient quantity*. To the Oil of Lavender add enough of the Alcohol to form *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Spirit of Lavender. This Spirit of Lavender contains five times the proportion of Oil of Lavender present in the Spirit of Lavender of the British Pharmacopœia of 1885." *Br.*

Spirit of lavender is used chiefly as a perfume, and as an ingredient in other preparations. The official spirit is about 33 per cent. stronger than the spirit of the U. S. P. 1870. The perfume usually sold under the name of *lavender water* is not a distilled spirit, but an alcoholic solution of the oil, with the addition of

other odorous substances. The following is given by Brande as one of the most approved recipes for preparing it. "Take of rectified spirit five gallons, essential oil of lavender twenty ounces, essential oil of bergamot five ounces, *essence of ambergris* [made by digesting one drachm of ambergris and eight grains of musk in half a pint of alcohol] half an ounce. Mix." The Br. spirit is double the strength of the U. S. preparation. It is a grateful stimulant and carminative when administered in sweetened water.

Dose, from five to twenty minims (0.3 to 1.3 Cc.).

Off. Prep.—Mistura Ferri Composita, U. S.

SPIRITUS MENTHÆ PIPERITÆ.

U. S., Br.

SPIRIT OF PEPPERMINT

(spîr'î-tûs mên'thæ pîp-ê-rî'tæ)

Essence of Peppermint; Teinture d'essence de Menthe, *Fr. Cod.*; Spiritus Menthe Piperitæ, *P. G.*; Pfefferminzspiritus, *Englische Pfefferminzessenz, G.*; Alcohol de menta piperita, *Sp.*

* "Oil of Peppermint, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Peppermint, bruised, *ten grammes* [or 154 grains]; Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the Oil of Peppermint in *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of Alcohol, add the Peppermint,¹ and allow it to macerate for twenty-four hours. Then filter through paper, and add, through the filter, enough Alcohol to make the Spirit measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

"Oil of Peppermint, 1 *fl. ounce* (Imperial measure) or 50 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity*. To the Oil of Peppermint add enough of the Alcohol to form *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Spirit of Peppermint. This Spirit of Peppermint contains five times the proportion of Oil of Peppermint present in the Spirit of Peppermint, and half the proportion of the *Essence of Peppermint* of the British Pharmacopœia of 1885." *Br.* It is now uniform in strength with the U. S. spirit.

The distilled spirit has no advantage over a simple solution of the oil in alcohol; and this mode of preparing it has been adopted both in the U. S. and British Pharmacopœias. It has long been popularly used under the name of *essence of peppermint*. The spirit of pep-

permint affords a convenient method of administering a dose of the volatile oil, being of such a strength that when dropped on loaf-sugar it may be taken without inconvenience.

Dose, ten to thirty minims (0.6 to 1.8 Cc.), given as just mentioned, or mixed with sweetened water.

Off. Prep.—Mistura Rhei et Sodæ, U. S.

SPIRITUS MENTHÆ VIRIDIS. U. S.

SPIRIT OF SPEARMINT

(spîr'î-tûs mên'thæ vir'î-dis)

Tinctura Olei Menthe Viridis, U. S. 1850; Essence of Spearmint; Grüne Minzessenz, *G.*

* "Oil of Spearmint, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Spearmint, bruised, *ten grammes* [or 154 grains]; Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the Oil of Spearmint in *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of Alcohol, add the Spearmint, and allow it to macerate for twenty-four hours. Then filter through paper, and add, through the filter, enough Alcohol to make the Spirit measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

The remarks made on the Spirit of Peppermint are equally applicable to this. Both are usually employed as carminatives.

Dose, ten to thirty minims (0.6 to 1.8 Cc.).

SPIRITUS MYRISTICÆ. Br.

SPIRIT OF NUTMEG [Essence of Nutmeg]

(spîr'î-tûs mÿ-ris'tî-cæ)

Teinture (alcoolé) d'essence de Muscade, *Fr.*; Muskatspirit, *G.*

"Oil of Nutmeg, 1 *fl. ounce* (Imperial measure) or 50 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity*. To the Oil of Nutmeg add enough of the Alcohol to form *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Spirit of Nutmeg. If the solution be not clear, agitate with a little *powdered talc*, and filter. This Spirit of Nutmeg contains five times the proportion of Oil of Nutmeg present in the Spirit of Nutmeg of the British Pharmacopœia of 1885." *Br.* It is double the strength of the U. S. 1890 spirit.

It is used chiefly for its flavor. Spirit of nutmeg was not retained in the U. S. P. (8th Rev.). It was made in the U. S. P. 1890 by dissolving 50 Cc. of oil of nutmeg in 950 Cc. of alcohol. (See *Oleum Myristicæ*.)

Dose, from five to twenty minims (0.3 to 1.3 Cc.).

Off. Prep.—Mistura Ferri Composita, *Br.*

¹ P. H. Utech suggests the maceration of the peppermint in water for two hours, washing and draining, before adding to the solution of the oil; water soluble matter is removed and a more permanent green color produced. He recommends the same treatment for the spearmint in making spirit of spearmint.

SPIRITUS RECTIFICATUS. Br.**ALCOHOL (90 PER CENT.) [Rectified Spirit]**

(spîr'î-tûs rêc-tî-fî-câ'tûs)

"A liquid containing 90 parts by volume of ethyl hydroxide, $\text{C}_2\text{H}_5\text{OH}$, and 10 parts by volume of water; obtained by the distillation of fermented saccharine liquids." *Br.*

See *Alcohol* (page 104).

SPIRITUS ROSMARINI. Br.**SPIRIT OF ROSEMARY**

(spîr'î-tûs rôs-mā-rî'nî)

Spiritus Anthos; Teinture d'essence de Romarin, Fr. Cod.; Rosmarinispiritus, G.; Alcohol de romero, Sp.

"Oil of Rosemary, 1 *fl. ounce* (Imperial measure) or 50 cubic centimetres; Alcohol (90 per cent.), a sufficient quantity. To the Oil of Rosemary add enough of the Alcohol to form ten fluid ounces (Imp. meas.) or five hundred cubic centimetres of the Spirit of Rosemary. This Spirit of Rosemary contains five times the proportion of Oil of Rosemary present in the Spirit of Rosemary of the British Pharmacopœia of 1885." *Br.*

The plant is no longer official. (See PART II.) This spirit is a grateful perfume, and is used chiefly as an ingredient in lotions and liniments.

SPIRITUS VINI GALlici. U. S., Br.**BRANDY**

(spîr'î-tûs vî'nî gāl'lî-cî)

"An alcoholic liquid obtained by the distillation of the fermented, unmodified juice of fresh grapes." *U. S.* "A spirituous liquid distilled from wine and matured by age, and containing not less than $36\frac{1}{2}$ per cent. by weight or $43\frac{1}{2}$ per cent. by volume of ethyl hydroxide." *Br.*

Spirit of French Wine; Eau de Vie, Cognac, Fr.; Brannntwein, Franzbranntwein, G.

All liquids which have undergone the alcoholic fermentation yield an ardent spirit by distillation. (See *Alcohol*, p. 104.) When the alcoholic liquid is wine, the product of the distillation is brandy. This ardent spirit is subject to variation, according to the character of the wine from which it is distilled. The best brandy is obtained from French wines, and the kinds called Cognac and Armagnac are most esteemed. Cognac is probably the most profitable wine producing region in the world, and has given its name to the most widely known brandy. Very large quantities of brandy are now made in California, but the taste is peculiar and easily distinguished from that of Cognac. Our Pharmacopœia formerly recognized French brandy exclusively; but since the

revision of 1860 all spirits have been admitted under that name, when obtained from the juice of grapes and sufficiently strong and pure to meet the requirements below specified.

Properties.—"A pale amber-colored liquid, having a distinctive odor and taste, and a slightly acid reaction. Brandy should be at least four years old. Its specific gravity should be not more than 0.941, nor less than 0.925 at 15.6°C . (60°F .), corresponding, approximately, to an alcoholic strength of 39 to 47 percent. by weight, or 46 to 55 percent. by volume, of absolute alcohol (see PART III, Alcohol Tables). If 100 Cc. of Brandy be slowly evaporated in a tared dish on a water-bath, the last portions volatilized should have an agreeable odor free from harshness (absence of *fusel oil* from grain or potato spirit); and the residue, when dried at 100°C . (212°F .), should not weigh more than 0.5 Gm. This residue should have no sweet or distinctly spicy taste (absence of *added sugar, glycerin, and aromatic substances*), and it should almost completely dissolve in 10 Cc. of cold water, forming a solution which is colored not deeper than light green by a few drops of ferric chloride T.S. diluted with 10 volumes of water (absence of more than traces of *oak tannin* from casks). If 50 Cc. of Brandy be shaken vigorously in a stoppered flask with 25 Gm. of kaolin, and, after standing half an hour, be filtered, the color of the filtrate should not be much lighter than that of the Brandy before treatment (absence of *caramel coloring*). To render 100 Cc. of Brandy distinctly alkaline to litmus, not more than 1 Cc. of normal potassium hydroxide V.S. should be required (limit of *free acid*)." *U. S.* Besides alcohol, water, and volatile oil, it contains coloring matter, tannin, cœnanthic ether described under *wine*, a little acetic ether, and a little aldehyde. Brandy is classed according to its color, as pale and high-colored. *Pale brandy* has a yellow color, derived from the cask in which it is kept. *High-colored brandy* has a deep-red color given to it, before importation, by burnt sugar (caramel), which is said to impart a more agreeable flavor. *Factitious brandy* is sometimes made from alcohol, deprived of fusel oil, and reduced to the proper proof by water, by adding to it acetic ether in the proportion of from half an ounce to an ounce to the gallon. *Oil of cognac*, which it is stated contains the aroma from wines, is made from compressed wine lees by placing it in a still with five times its bulk of water, 2 per cent. of newly slaked lime, 1 per cent. of potash, and 1 per cent. of common salt. The stirring apparatus is set in motion, steam applied, the heat allowed to rise gradually to 240°C . (464°F .), and the green oil separated; the average yield is very small (.003 per cent.); the oil is then rectified, and 2 grammes of it are added to 100 litres of 50 per cent. alcohol to impart the odor and taste which so-called "best brandy"

should have. The proper color is then given by burnt sugar. The spurious liquid may be known by its leaving on evaporation a residue, containing sugar and no tannin, the absence of the latter being shown by the evaporated portion not striking a black color with ferric salts. The nature of the liquid may also be detected by the absence of aldehyde. For modes of detecting impurities in brandy and other ardent spirits, see Allen, *Com. Org. Anal.*, 3d ed., i. 143 *et seq.*

Uses.—Brandy is esteemed as a cordial and stomachic, and is frequently given, in the form of toddy or milk punch, in the sinking stages of low fevers. In the late London Pharmacopœia there was an official preparation of it, called *Mistura Spiritus Vini Gallici*, consisting of brandy, cinnamon water, the yolks of eggs, sugar, and oil of cinnamon. This, though a convenient form for the administration of brandy, was subsequently omitted. It is now again official in the British Pharmacopœia, but the oil has been left out. If prepared with the U. S. cinnamon water, it would certainly be sufficiently flavored without the addition of the oil.

Off. Prep.—*Mistura Spiritus Vini Gallici*, Br.

STAPHISAGRIA. U. S. (Br.)

STAPHISAGRIA [Stavesacre]

(stăph-i-să'grî-ă)

"The ripe seed of *Delphinium Staphisagria* Linné (Fam. *Ranunculacæ*)," U. S. "The dried ripe seeds of *Delphinium Staphisagria*, Linn." Br.

Staphisagria Semina, Br.; *Semen Staphisagriae*, *Staphidiagriae* or *Pedicularis*; *Stavesacre Seeds*; *Staphisalgre*, Fr. Cod.; *Stephanskörner*, *Läusekörner*, G.; *Staßsagria*, It.

Delphinium Staphisagria, L., or stavesacre, is a handsome, annual or biennial plant, one or two feet high, with a simple, erect, downy stem, and palmate, five- or seven-lobed leaves, supported on hairy footstalks. The flowers are bluish or purple, in terminal racemes, with pedicels twice as long as the flower, and bracteoles inserted at the base of the pedicel. The nectary is four-leaved and shorter than the petals, which are five in number, the uppermost projected backward so as to form a spur, which encloses two spurs of the upper leaflets of the nectary. The seeds are in straight oblong capsules. The plant is a native of the south of Europe. E. M. Holmes calls attention to the remarkable fact that the plant in the English botanic gardens hitherto considered to be *Delphinium Staphisagria* is in reality another species, *i.e.*, *Delphinium pictum*, Willd. The author accounts for the absence of the true plant in botanic gardens partly by the fact that it is only half-hardy in Great Britain, while *D. pictum* is hardy, and partly by the reason that the illustrations in several works on

medicinal plants—even in Bentley and Trimen's "Medicinal Plants" are incorrect or unreliable. The two species are distinguished as follows: *D. Staphisagria* has very hairy stems, glandular hairs being mixed with the long spreading soft hairs; flowers that when well-developed have an ultramarine blue tint; a calyx with very short or almost obsolete spur; carpels containing only four or five seeds. *D. pictum*, Willd., has shorter soft hairs, but no glandular hairs on the stems; the flowers are of a pale lilac color; the spur is as long as the calyx segments; each carpel contains ten or twelve seeds, and these are only half the size of those of *D. Staphisagria*. The true *D. Staphisagria* extends from Teneriffe around both the northern and southern coasts of the Mediterranean to Asia Minor. It is quite possible, therefore, that varieties having blossoms of different tints may occur. The evidence obtainable, however, goes to show that the form of the plant from which the seed of commerce is obtained—which, by the way, will not germinate, or only very rarely—has clear blue flowers. (*Y. B. P.*, 1899, 390.)

Properties.—The seeds of stavesacre are officially described as "irregularly tetrahedral, one side convex, 5 to 6 Mm. long and 3 to 6 Mm. broad; externally blackish-brown, becoming lighter with age, strongly reticulate; endosperm oily, enclosing a small, straight embryo; odor slight; taste intensely bitter and acid." U. S. Their virtues are extracted by water and alcohol. Analyzed by Lassaigne and Feneulle they yielded a brown and a yellow bitter principle, a volatile oil, a fixed oil, albumen, a nitrogenous substance, a mucilaginous saccharine matter, mineral salts, and a peculiar alkaloid called *delphinine*¹ or *delphinia*, which exists in the seeds combined with an excess of malic acid. Marquis, in Dragendorff's laboratory in 1877, isolated the following four alkaloids: *delphinine*, $C_{22}H_{35}NO_6$, a crystallizable alkaloid, of bitter taste, weak alkaline reaction, soluble in alcohol, ether, and chloroform; *delphinoidime*, $C_{42}H_{65}N_2O_7$, amorphous, soluble in ether, alcohol, chloroform, reaction strongly alkaline, fusing point from 110° to 120° C.; *delphisine*, $C_{27}H_{46}N_2O_4$, crystallizing in warty aggregations, soluble in ether, alcohol, and chloroform; *staphisagrine*, $C_{22}H_{35}NO_5$, only obtained amorphous, difficultly soluble in water and ether, easily soluble in alcohol and chloroform, of bitter taste, fusing point 90° C., of alkaline reaction in alcoholic solution. (*Pflanzenstoffe*, 2d ed., 1884, 617.) The total amount of alkaloids is about 1 per cent. According to Charalampi Kara-Stojanow (*In. Dis.*, Dorpat, 1890), delphinine and delphisine have the same com-

¹ If delphinine be rubbed up with an equal quantity of malic acid, and some drops of concentrated sulphuric acid added, there will be produced an orange-red color passing into rose, growing deeper after some hours, and finally changing from the edges to violet, and at last becoming cobalt blue. (Tattersall, *Chem. News*, 41.) It is stated that no other alkaloid and no other organic acid, except malic, affords this reaction.

position, $C_{51}H_{42}NO_7$, crystallize from their solutions in ether and petroleum benzin in identical forms, and have their melting points at $191^\circ C.$ and $189^\circ C.$, while delphinoidine has the formula $C_{25}H_{42}NO_4$. Ahrens (*Ap. Ztg.*, 1899, 361) obtained from the residue of the seeds of *D. staphisagria*, from which delphinine, delphinoidine, delphisine and staphisagraine had been extracted, the alkaloid *staphisagrine* (*Ber. d. Chem. Ges.*, 1899, 1581). For Katz's process for extracting delphinine, see *Ph. Ztg.*, 1900, 735.

Uses.—The seeds were formerly used as an emetic and cathartic, but have been abandoned in consequence of their violence. A strong tincture has been employed as an embrocation in *rheumatism*. The ointment is used to destroy lice and the itch-mite. Bazin has used the extract internally in *eczema* in doses of a grain and a half (0.096 Gm.). (*Ann. Thér.*, 1851.) *Staphisagria* should, however, never be used internally, and when it is applied externally, care should be exercised not to put it on an abraded scalp, but only upon the unbroken epidermis. In some countries the seeds are used like *Cocculus Indicus* to intoxicate fish.¹

Dose, one grain (0.065 Gm.).

Off. Prep.—Fluidextractum *Staphisagriae*, U. S.; Unguentum *Staphisagriae*, Br.

STILLINGIA. U. S.

STILLINGIA (Queen's Root)

(stil'-lin'-gi-a)

"The dried root of *Stillingia sylvatica* Linné (Fam. *Euphorbiaceæ*)." *U. S.*

Silver Leaf, Queen's Delight, Yaw Root; Stillingie, Fr., G.

¹When given in poisonous doses to the lower animals, *delphinine* produces excessive salivation, followed by violent and repeated vomiting, great disturbance of respiration, failure of heart action, gradual enfeeblement of voluntary motion and of sensation, and a peculiar fibrillary spasm of the muscles of the abdomen, which is said to be characteristic of the poisoning. Elevation of temperature and glycosuria have both been noticed; death is said to occur always from failure of respiration, though the heart is greatly enfeebled and finally ceases in diastole. According to Gauthier, the period of depression of the heart and of sensibility is preceded by one of excitement. The pupils are dilated and the motor nerve finally paralyzed. (*L. M. R.*, Oct. 1887.) Turnbull, in his work *On the Medical Properties of the Ranunculaceæ*, states that pure delphinine may be given to the extent of three or four grains a day, in doses of half a grain each, without exciting vomiting, and without producing much intestinal irritation, though it sometimes purges. In most instances it proves diuretic, and gives rise to sensations of heat and tingling in various parts of the body. Externally, it acts like veratrine, but, according to Turnbull, produces more redness and burning and less tingling than that substance. He has employed it in neuralgia, rheumatism, and paralysis. It may be applied by friction, in the form of ointment or alcoholic solution, in proportions varying from ten to thirty grains of the alkaloid to an ounce of the vehicle, and the friction should be continued till a pungent sensation is produced. Turnbull probably had an impure alkaloid; the doses just mentioned would not be safe with a pure delphinine.

Staphisagrine is said to act like delphinine, except that it does not depress the heart so much or produce fibrillary contractions. Although cases of human poisonings have occurred with *staphisagria*, we know

Stillingia sylvatica, L., *Mant.* (1767) 126; Willd., *Sp. Plant.* iv. 588; B. & T. 241.—This is an indigenous perennial plant, commonly called *Queen's delight*, with herbaceous stems, two or three feet high, and alternate, sessile, oblong or lanceolate-oblong, obtuse, serrulate leaves, tapering at the base, and accompanied with stipules. The male and female flowers are distinct upon the same plant. They are yellow, and arranged in the form of a spike, of which the upper part is occupied by the male, the lower by the female flowers. The male florets are scarcely longer than the bracteal scales. The plant grows in pine barrens from Virginia to Florida, flowering in May and June. When wounded it emits a milky juice. For structural characteristics of *stillingia*, see *D. C.*, 1898, 5.

The root, which is the part used, is large, thick, and woody. It is officially described as "slenderly fusiform, usually in cut pieces, of variable length and 0.5 to 3 Cm. in diameter; externally reddish-brown, longitudinally wrinkled; fracture fibrous, bark light reddish-brown, 0.5 to 4 Mm. thick, spongy, finely fibrous, with numerous resin cells, easily separable from the porous, radiate wood; odor distinct; taste bitter, acid, and pungent." *U. S.* The odor is slight, peculiar, and somewhat oleaginous, but in the recent root is said to be strong and acrimonious. The taste is bitterish and pungent, leaving an impression of disagreeable acrimony in the mouth and fauces. It imparts its virtues to water and alcohol. H. R. Frost thinks that the active principle is somewhat volatile, and states that the root loses much of its activity when long kept. W. Saunders has obtained from the root a volatile oil, which he found to possess the odor, taste, and peculiar acrimony of the root in a high degree. He procured six and a quarter ounces from five pounds of the dried root. It had a thick consistence, and required the addition of alcohol to render it fit for manipulation. Wm. Bichy (*A. J. P.*, 1885, p. 529) found an alkaloid which he named *stillingine*. It was obtained as an amorphous powder, volatilizable on heating, forming a sulphate in fine scale-like crystals.

Uses.—In large doses *stillingia* is emetic and cathartic, in smaller doses alterative, with some influence over the secretions. It has been long popularly used in South Carolina, but was first introduced to the notice of the profession by Thomas Young Simons (*Amer. Med. Recorder*, 1828, vol. xiii. p. 312) as a valuable alterative remedy in *syphilitic affections* and other affections ordinarily requiring the use of mercury. From the reports in its favor there seems no reason to doubt the efficacy of this medicine in *secondary syphilis, scrofula, cutaneous diseases, chronic hepatic affections*, and other complaints

of none in which the result has been fatal. The symptoms are similar to those produced in the lower animals. Kobert states that the alkaloids of *staphisagria* all resemble acontine in their action, but that delphinidine has some narcotic action.

ordinarily benefited by alterative medicines. It is best given in the form of the official fluid-extract.

Dose, half a fluidrachm increased to a fluidrachm (1.8 to 3.75 Cc.). *Stillingia* is sometimes advantageously combined with sarsaparilla and other alteratives.¹

Off. Prep.—Fluidextractum Stillingiæ, U. S.

STRAMONII SEMINA. Br.

STRAMONIUM SEED

(strā-mō'nī-i sēm'i-nā)

"The dried ripe seeds of *Datura Stramonium*, Linn." Br.

Semen Stramonii, P. G.; Thornapple; Stramoine, Pomme épineuse, Semences (Graines) de Stramoine, Fr.; Stechapfelsamen, G.; Stramonio, It.; Estramonio, Sp.

Datura Stramonium, L., *Sp. Pl.* (1753) 179; Willd., *Sp. Plant.* i. 1008; Bigelow, *Am. Med. Bot.*, i. 17; B. & T. 192.—The *thornapple* is an annual plant, of rank and vigorous growth, usually about three feet high, but in a rich soil sometimes six feet or more. The root is large, whitish, and furnished with numerous rootlets. The stem is erect, round, smooth, somewhat shining, simple below, dichotomous above, with numerous spreading branches. The leaves, which stand on short round footstalks in the forks of the stem, are five or six inches long, of an ovate-triangular form, irregularly sinuated and toothed at the edges, unequal at the base, dark green on the upper surface, and pale beneath. The flowers are large, axillary, solitary, and peduncled, having a tubular, pentangular, five-toothed calyx, and a funnel-shaped corolla with a long tube, and a waved plaited border, terminating in five acuminate teeth. The upper portion of the calyx falls with the deciduous parts of the flower, leaving its base, which be-

comes reflexed and remains attached to the fruit. This is a large, fleshy, roundish-ovate, four-valved, four-celled capsule, thickly covered with sharp spines, and containing numerous seeds, attached to a longitudinal placenta in the centre of each cell. It opens at the summit. There are two varieties of this species of *Datura*, one with a green stem and white flowers, the other with a dark reddish stem minutely dotted with green, and purplish flowers striped with deep purple on the inside. The latter, however, is considered by some botanists as a distinct species, being the *D. Tatula* of Linnaeus. The properties of both are the same.

It is doubtful to what country this plant originally belonged. Many European botanists refer it to North America, while we in return trace it to the old continent. Nuttall considers it as having originated in South America or Asia, and it is probable that its native country is to be found in some part of the East. It is said to grow wild, abundantly in Southern Russia, from the borders of the Black Sea eastward to Siberia. Its seeds, being retentive of life, are taken in the earth put on shipboard for ballast from one country to another, not infrequently springing up upon the passage, and thus propagating the plant in all regions which have any commercial connection. In the United States it is found everywhere in the vicinity of cultivation, frequenting dung heaps, the road sides and commons, and other places where a rank soil is created by the deposited refuse of towns and villages. Its flowers appear from May to July or August, according to the latitude. Where the plant grows abundantly, its vicinity may be detected by the rank odor which it diffuses to some distance around. All parts of it are medicinal. The leaves, seeds, and root were formerly recognized by the U. S. P., the leaves and seed in the U. S. P. 1890, but in the U. S. P. (8th Rev.) the seeds were not included and the leaves alone are official under the title *Stramonium*.² The leaves may be gathered at any time from the appearance of the flowers till the autumnal frost. In this country the plant is generally known by the name of *Jamestown* (vulgo, *Jimson*) weed, derived probably from its having been first observed in the neighborhood of that old settlement in Virginia.

¹ *Syrupus Stillingiæ Compositus*. Compound Syrup of *Stillingia*.—This syrup, notwithstanding its reputation as a model of polypharmaceutical skill, is largely used in the West and South. John King makes it as follows: Take of Queen's Root (*Stillingia*) 2 lbs. [avoidridupols]; Turkey-corn Root (*Corydalis*) 2 lbs. [av.]; Blue-flag Root (*Iris versicolor*) 1 lb. [av.]; Elder Flowers 1 lb. [av.]; Pipsissewa Leaves (*Chimaphila*) 1 lb. [av.]; Coriander ½ lb. [av.]; Prickly Ash Berries (*Xanthoxylum*) ½ lb. [av.]; Sugar, Refined, 24 lbs. [av.]; Water, q. s., Alcohol, 76 per cent., q. s. Grind and mix the vegetable drugs together, place them in a convenient vessel, cover them with alcohol of 76 per cent., and macerate for three days. Then transfer the whole to a percolator and gradually pour alcohol on top until 4 pints of tincture have been obtained, which retain and set aside. Then continue the percolation with water, and of this second percolate reserve so much as contains a sensible amount of alcohol, and distil or evaporate the latter from it. Continue the percolation by water until the solution obtained is almost tasteless, and boil down this weaker infusion until, when added to the second solution, after the evaporation of its alcohol, it will make 24 pints. To these two solutions combined add the sugar, and dissolve it by heat, carefully removing any scum which arises as it begins to boil, and if it exceeds 28 pints, evaporate to that quantity with constant stirring. Then remove from the fire, and, when nearly cold, add the 4 pints of reserved alcoholic tincture and make 4 gallons of syrup, each pint of which will be equal to 4 fluid-ounces of the ingredients. The 24 pounds of sugar, when added to the 24 pints of solution, will always make more than 28 pints. (N. E., May, 1880.)

² Under the name of *DATURÆ FOLIA* or *Datura Leaves*, the Indian and Colonial Addendum recognizes the dried leaves of *Datura fastuosa*, Linn., var. *alba*, Nees (Natural Order, *Solanaceæ*), and of *Datura Metel*, Linn.; and under the name of *DATURÆ SEMINA*, *Datura seeds*, the dried seeds of the first-named of these species. The leaves are described as "ovate, acuminate, with long petioles and sinuate-dentate margins; often unequal at the base. The larger are seven or eight inches (seventeen or twenty centimetres) long, and four or five inches (ten or twelve and a half centimetres) broad." Br. Add.

The seeds are somewhat wedge-shaped, with rounded, thickened, furrowed, wavy margins, strongly compressed laterally; from one-sixth of an inch to one-fifth of an inch (four to five millimetres) broad, and about one-twenty-fifth of an inch (one millimetre) thick. The hilum is situated on one edge and extends from about the middle to the acute end of the seed. The testa is finely pitted and reticulated, and is of a dull yellowish-brown color; it is comparatively thick, and encloses a narrow translucent endosperm which surrounds a curved embryo. Br. Add.

In India *Datura alba*, *D. ferox*, and *D. fastuosa* are employed as poisons. Under the names of *Man t'o lo fa*, *Wan t'o lo hua*, and *Nau yeung fa*, the Chinese use as a medicine the flowers of the *Datura alba*; according to Frank Browne, they contain 0.485 per cent. of hyoscyne, free from other alkaloids. *El Bethene*, a *Datura* of the Sahara Desert, is capable of causing delirium, coma, and death, and it is probable that all the species of the genus are poisonous. A. R. L. Dohme (*Proc. A. Ph. A.*, 1894, 231) examined stramonium to determine the value in alkaloid of the various parts of the plant; he found that, in general, the fresh parts yielded more than the dried parts; the stems contained the most alkaloid, the seeds next, then the leaves, and the roots the least of all.

1.—The fresh leaves when bruised emit a fetid narcotic odor, which they lose upon drying. Their taste is bitter and nauseous. These properties, together with their medicinal virtues, are imparted to water and alcohol. Water distilled from them, though possessed of their odor in a slight degree, is destitute of their active properties. They contain, according to Promnitz, 0.58 per cent. of gum, 0.6 of extractive, 0.64 of green starch, 0.15 of albumen, 0.12 of resin, 0.23 of saline matters, 5.15 of lignin, and 91.25 of water. The leaves, if carefully dried, retain their bitter taste. They are officially described as "usually of a dark green or grayish-green color, much wrinkled and matted together; petiolate, 6 to 20 Cm. long, inequilaterally ovate, acuminate, very oblique at the base, the large teeth few, acute, with rounded sinuses; thin, brittle; odor distinct, heavy, and narcotic; taste nauseous. The powder contains few hairs and has numerous rosette-shaped calcium oxalate crystals from 0.010 to 0.020 Mm. in diameter." *U. S.*

The mesophyll of stramonium contains cluster crystals of calcium oxalate. J. S. Ward has found commercial stramonium leaves freely adulterated with those of *Carthamus helenioides* and *Xanthium Strumarium*. (*P. J.*, lxvi. 326.) For a paper on the structure of the leaves of *D. Stramonium*, *A. Belladonna*, and *H. niger* by Schlotterbeck and van Zwaluwenburg, the reader is referred to *Proc. A. Ph. A.*, 1897, 202.

2.—The seeds are small, kidney-shaped, pitted and wrinkled, flattened on the sides, of a dark-brown almost black color, inodorous unless bruised, and of the bitter, nauseous taste of the leaves, with some degree of acrimony. The testa is dull brownish black, hard, and encloses a cylindrical curved embryo, which is embedded in a whitish oily albumen. They are much more energetic in their action on the system than are the leaves. Hirtz and Hopp inferred from their experiments that one part of an extract prepared from them was equal in strength to five parts of an extract prepared in precisely the same manner from the leaves. (*Ann. Thér.*, 1862, p. 22.) Geiger and Hesse suc-

ceeded in isolating an alkaloid, to which the name *daturine* was given, and which Trommsdorff has repeatedly procured by their process. Von Planta (*A. J. P.*, 23, p. 38) found that daturine was identical with atropine, and this result has since been confirmed; but Ladenburg (*Ber. d. Chem. Ges.*, 13, p. 909) found that *Datura Stramonium* contains two alkaloids, which he designated as *heavy daturine* and *light daturine*.

The more difficultly soluble heavy daturine fuses at 113.5° to 114° C. (237° to 237.2° F.), and must be considered as a mixture of *atropine* and *hyoscyamine*. It yields a gold salt fusing between 135° and 150° C. (275° and 302° F.), out of which, by crystallization repeated six times and by rejection each time of the mother liquor, is obtained hyoscyamine gold-chloride fusing at 158° to 160° C. (316.4° to 320° F.). From the mother liquors by evaporation is obtained nearly pure atropine gold chloride fusing at 135° to 140° C. (275° to 284° F.). If the heavy daturine be repeatedly crystallized out of dilute alcohol, pure atropine can be isolated from it, fusing at 113.5° to 114.5° C. (237° to 238° F.), and yielding a lustreless gold salt fusing at 135° to 139° C. (275° to 282.2° F.). The light daturine is the alkaloid which Ladenburg and Meyer in a previous study had shown to be identical with hyoscyamine. Hence *Datura Stramonium* contains the two alkaloids *atropine*, $C_{17}H_{23}NO_3$, and *hyoscyamine*, isomeric with the other, which *Atropa Belladonna* also contains. (*A. J. P.*, 1884, 440.) The mother liquors from which hyoscyamine is obtained yield a difficultly crystallizable base, first called hyoscyne, but now known as *scopolamine*. Its gold salt is more difficultly soluble than the gold salts of atropine and hyoscyamine, and affords a means of separation. The base, when purified, can be crystallized out of ether in colorless crystals, melting at 59° C. Its formula is $C_{17}H_{21}NO_4$, and it is decomposed by boiling with baryta water into *scopolin*, $C_8H_{13}NO_2$, and *atropic acid*, $C_9H_9O_4$. (Schmidt, *Pharm. Chemie*, 3te Auf., ii. 1339.)

Gérard (see *J. P. C.*, 1892, 8) studied *daturic acid* obtained from stramonium seed. D. Holde has, by means of benzene, extracted from stramonium seed 16.7 per cent. of a fixed oil (*P. J.*, lxx. p. 90). This has been examined by J. M. Baird and F. E. Sleeper, see *Proc. A. Ph. A.*, 1903, 324.

Assay of Stramonium.—"The method to be employed is identical with that given on page 228 for *Belladonna Leaves*, using *ten grammes* of *Stramonium*, in No. 60 powder." *U. S.*

Uses.—Stramonium is so similar to *belladonna* in the symptoms produced by it in small or large doses, in its toxicity and its general physiological and therapeutic action, that the two drugs are practically identical. Furthermore, they are about the same strength in activity, so the preparations may be used in similar doses. Stramonium has been employed in all the conditions for which belladonna is more

commonly used, but has acquired special repute in the treatment of *asthma*, this probably being due to the fact that the practice of smoking *Datura ferox* in that disease was introduced into Great Britain from the East Indies by General Gent, and that afterwards the English species was substituted for that employed in Hindostan. Formerly the roots were chiefly used, but at present the dried leaves are exclusively employed. They may be smoked in a common tobacco pipe, or may be made into cigars, but are commonly employed in the form of a powder, to be burnt upon a saucer; mixed with potassium nitrate they constitute the basis of most of the proprietary asthmatic powders. Death is said to have been produced by the free use of the India *Datura ferox*, but it seems hardly possible that the species which is found in North America would produce such a result.

Of the parts of the plant employed, the leaves and the seeds are the most powerful. They may be given in the dose of a grain (0.065 Gm.) twice a day; an extract made by evaporating the decoction, in one-quarter or one-half the quantity. The inspissated juice of the fresh leaves was formerly very commonly prescribed; but the alcoholic extract is now almost exclusively used, the dose being half a grain (0.032 Gm.). (See *Extractum Stramonii*.) A tincture and a fluidextract of the leaves are also official, to which the reader is referred; the fluidextract and extract of the seeds are no longer official. The dose should be gradually increased till the narcotic operation becomes evident, or relief from the symptoms of the disease is obtained.

Dose, one to five grains (0.065 to 0.32 Gm.) of the leaves (*Stramonium*, *U. S.*).

Cod.*; *Feuilles de Stramolne*, *Fr.*; *Folia Stramonii*, *P. G.*; *Stechapfelblätter*, *G.*; *Stramonio*, *It.*; *Estramonio* (*Hoja de*), *Sp.*

For description, official assay, uses, dose, etc., of stramonium, the reader is referred to the preceding article, *Stramonii Folia*.

STRONTII BROMIDUM. U. S.

STRONTIUM BROMIDE

(strōn'tī-i brō'mj-dūm)

"It should contain not less than 97 percent. of pure Strontium Bromide, and should be kept in glass-stoppered bottles." *U. S.*

Bromure de Strontium, *Fr. Cod.*; Strontiumbromid, *G.*; Bromuro Estronico, *Sp.*

This salt, made official in the *U. S. P.* 1890, may be made by burning strontium in bromine vapor, by dissolving strontium carbonate in hydrobromic acid, or by substituting hydrobromic acid for hydrochloric acid in the latter part of the process given for preparing strontium salts. (See page 1186.)

Properties.—It is officially described as in "colorless, transparent, hexagonal crystals; odorless and having a bitter, saline taste. Very deliquescent. Soluble in about 1 part of water at 25° C. (77° F.), and in 0.4 part of boiling water. It is readily soluble in alcohol, and is precipitated from this solution upon the addition of an equal volume of ether, in which it is insoluble. When heated, the crystals at first melt, and then lose all their water (30.4 percent.). The anhydrous salt fuses at 630° C. (1166° F.). To a non-luminous flame the salt communicates an intense red color. Its aqueous solution is neutral to litmus paper. With calcium sulphate T.S., the aqueous solution (1 in 20) slowly forms a white precipitate of strontium sulphate, insoluble in dilute acids; the same reaction occurs more quickly with diluted sulphuric acid and the readily soluble sulphates. With potassium chromate T.S. it forms a yellow precipitate of strontium chromate, soluble in acetic acid. With ammonium carbonate T.S., or sodium carbonate T.S., it forms a white precipitate of strontium carbonate, soluble, with effervescence, in acetic acid. If to 10 Cc. of the aqueous solution of the salt (1 in 20) 1 Cc. of chloroform be added, and then chlorine water, which has been diluted with an equal volume of water, introduced cautiously, drop by drop, with constant agitation, the liberated bromine will dissolve in the chloroform, imparting to it a yellow to orange color, free from any violet tint (absence of *iodide*). The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If 1 Gm. each of Strontium Bromide and sodium acetate be dissolved in 5 Cc. of distilled water, and the solution made slightly acid by the addition of from 3 to 5 drops, or a sufficient quantity, of diluted acetic acid, the solution should not, upon the addition of 5 drops of potassium dichromate T.S. and agitating, become cloudy within three minutes (limit of *barium*). If 0.5 Gm. of Strontium Bromide be dissolved in about 50 Cc.

of distilled water, and a few drops of potassium chromate T.S. be added, it should require the addition of not less than 27.4 (27.48) Cc. nor more than 29.4 Cc. of tenth-normal silver nitrate V.S. to produce a permanent red color (corresponding to at least 97 percent. of pure Strontium Bromide)." *U. S.* For further tests, see *Proc. A. Ph. A.*, 1897, 608.

Uses.—Strontium bromide has been strongly commended as a substitute for potassium bromide in the treatment of *epilepsy* and allied conditions. It depends for its action on the nervous system upon the presence of bromine in it, and appears to act upon the nervous centres in much the same manner as does the corresponding salt of potassium. Its influence upon the general nutrition is much more favorable than is that of the potassium salt, and it is much less apt to produce the disagreeable effects of bromism. Moreover, it is less irritating to the gastro-intestinal mucous membranes, on which, indeed, it often seems to exert a beneficial influence, and it probably acts as a powerful intestinal antiseptic. For these reasons many cases of epilepsy tolerate it much better than they do other bromides. In the clinical experience of H. C. Wood, however, it has seemed to be in its anticonvulsive influence among the least powerful and certain of its class. Possibly this result has been due to Wood not having employed it in sufficient dose, he never having administered more than two drachms a day, while the French observers affirm that it may be given with great advantage in the daily dose of three drachms. Strontium bromide is further stated by Sée to have an extraordinary influence in the reduction of the excretion of sugar in *diabetes*, and to be a valuable remedy in the treatment of *gastric dilatation* and *catarrh*.

Dose, fifteen to thirty grains (1 to 2 Gm.).

STRONTII IODIDUM. U. S.

STRONTIUM IODIDE

(strôn'tî-i î-ôd'î-düm)

"It should contain not less than 98 percent. of pure Strontium Iodide, and should be kept in small, glass-stoppered vials, carefully protected from light." *U. S.*

Iodure de Strontium, *Fr.*; Strontiumjodid, *G.*

This official salt may be made by evaporating a solution of hydriodic acid saturated with strontium hydroxide or carbonate.

Properties.—It is officially described as in "colorless, transparent, hexagonal plates; odorless, and having a bitter, saline taste. Deliquescent, and colored yellow by exposure to air and light. Soluble in about 0.5 part of water at 25° C. (77° F.), and in 0.27 part of boiling water. Also soluble in alcohol, and slightly soluble in ether. When cautiously heated,

the crystals melt and gradually lose their water (24.05 percent.), becoming anhydrous. At a red heat, the salt is decomposed, losing iodine, and leaving a residue of strontium oxide. To a non-luminous flame it imparts an intense red color. Its aqueous solution is neutral, or very slightly alkaline to litmus paper. With calcium sulphate T.S. it slowly forms a white precipitate of strontium sulphate, insoluble in diluted acids; the same reaction occurs more quickly with diluted sulphuric acid and the readily soluble sulphates. With potassium chromate T.S. it forms a yellow precipitate of strontium chromate, soluble in acetic acid. With ammonium carbonate T.S., or sodium carbonate T.S., it forms a white precipitate of strontium carbonate, soluble, with effervescence, in acetic acid. If to 5 Cc. of the aqueous solution of the salt (1 in 20) 1 Cc. of chlorine water be added, iodine will be liberated, and impart to the solution a light reddish-brown color; on agitating the mixture with a few drops of chloroform, the latter will acquire a violet color. The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If 1 Gm. each of Strontium Iodide and sodium acetate be dissolved in 5 Cc. of distilled water, and the solution be made slightly acid by the addition of from 3 to 5 drops, or a sufficient quantity, of diluted acetic acid, the solution should not, upon the addition of 5 drops of potassium dichromate T.S., and agitating, become cloudy within three minutes (limit of *barium*). If 0.5 Gm. of Strontium Iodide be dissolved in about 100 Cc. of distilled water contained in a flask, and 25 Cc. of tenth-normal silver nitrate V.S., 5 Cc. of nitric acid, and 5 Cc. of ferric ammonium sulphate T.S. be successively added, the flask stoppered and thoroughly shaken, then the addition of not less than 1.7 Cc. nor more than 3.1 Cc. of tenth-normal potassium sulphocyanate V.S. should be required to produce a permanent red tint (corresponding to 98 percent. of pure Strontium Iodide)." *U. S.*

Uses.—This salt has been brought forward as a means of obtaining the alterative influence of an iodide without irritating the intestinal tract or depressing the general nutrition. It contains about 56.5 per cent. of iodine, and, although its actual value has scarcely as yet been made out, may be substituted for potassium iodide in various diseases.

Dose, five to fifteen grains (0.32 to 1 Gm.).

STRONTII SALICYLAS. U. S.

STRONTIUM SALICYLATE

(strôn'tî-i sāl-j-cy'läs)

"It should contain not less than 98.5 percent. of pure Strontium Salicylate [(C₆H₄.OH.

$\text{COO})_2\text{Sr} + 2\text{H}_2\text{O}]$, and should be kept in well-stoppered bottles, protected from heat and light." *U. S.*

Strontium Salicylicum; Salicylate de Strontium, *Fr.*; Salicylsaures Strontium, Strontiumsalicylat, *G.*

Preparation.—This salt is made by adding 10 parts of salicylic acid to 100 parts of hot water and then adding 5.3 parts of pure strontium carbonate, filtering, evaporating and crystallizing.

Properties.—It is officially described as "a white, crystalline powder; odorless, and having a sweetish, saline taste. Soluble in 18 parts of water and in 66 parts of alcohol at 25° C. (77° F.), in 3.5 parts of boiling water, and in 10.5 parts of boiling alcohol. When heated, the salt is decomposed, giving off inflammable vapors and an odor of phenol, and finally leaving a gray residue of strontium carbonate. To a non-luminous flame its solution imparts an intense red color. Its aqueous solution should be colorless, and slightly alkaline to litmus paper. Ferric chloride T.S., when added to an excess of a concentrated aqueous solution of the salt, produces a violet precipitate; but when added to a very dilute solution (1 in 100), it produces a deep violet-blue color. If copper sulphate T.S. be added to the aqueous solution (1 in 20), a green color will be produced. On adding about 1 Cc. of concentrated sulphuric acid to about 0.2 Gm. of the salt, in a test-tube, then about 1 Cc. of methyl alcohol, in drops, and heating the mixture to boiling, the odor of methyl salicylate will be evolved. With calcium sulphate T.S., the aqueous solution of the salt (1 in 20) slowly forms a white precipitate of strontium sulphate, insoluble in dilute acids; the same reaction occurs more quickly with diluted sulphuric acid or a readily soluble sulphate. With potassium chromate T.S., Strontium Salicylate forms a yellow precipitate of strontium chromate, soluble in acetic acid. With ammonium carbonate T.S., or sodium carbonate T.S., the salt forms a white precipitate of strontium carbonate, soluble, with effervescence, in acetic acid. If to the aqueous solution of Strontium Salicylate (1 in 20) 5 drops of hydrochloric acid be added, and the mixture agitated and filtered, the filtrate should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If 2 Gm. of Strontium Salicylate be agitated with 10 Cc. of diluted acetic acid, heated, cooled, and filtered, the filtrate, upon the addition of 5 drops of potassium dichromate T.S., should not become cloudy within three minutes (limit of *barium*). If to 0.5 Gm. of Strontium Salicylate, contained in a porcelain crucible, 1 Cc. of sulphuric acid be added, the mixture cautiously heated until no more vapors are given off, the residue again moistened with a few drops of the acid, again heated, and finally ignited until white and of constant weight, the residue of strontium sulphate should weigh not less than 0.227 Gm." *U. S.*

Uses.—Strontium salicylate when taken internally is slowly decomposed in the alimentary canal with the liberation of salicylic acid, which acid or its educts can be detected in the urine shortly after administration. As a salicylate, the strontium salt is of especial value in subacute *rheumatic* affections, acting more slowly and persistently than most of the other allied salts, and having much less tendency to disturb the digestion. It may be administered in capsule, but should never be given in the form of compressed pills.

Dose, five to thirty grains (0.32 to 2.0 Gm.).

STRONTIUM.

STRONTIUM

(strōn'tī-ŭm)

Sr = 86.94

Strontium belongs to the alkaline earth-group of metals along with barium and calcium. It is a yellow metal, of the sp. gr. 2.5, somewhat harder than lead, and is sufficiently malleable to be hammered out into thin plates. It oxidizes quickly on exposure to air, and hence must be kept under naphtha, like the alkali metals. It has so far been prepared only in a small way by electrolysis from the chloride or the hydroxide, the best procedure being that of Bunsen and Matthiessen.

For the preparation of pure salts, Barthe and Falières found that the following method permits the preparation of pure strontium salts with comparative ease, and has the advantages that no heat is necessary, and that the chemicals employed need not be pure.

Dissolve natural strontium carbonate (or the sulphide obtained by reduction of the sulphate) in just sufficient diluted hydrochloric acid (1 to 5); it will be an advantage if some of the carbonate or sulphide remains undissolved. The clear liquid, which contains calcium, barium, and strontium salts, besides small quantities of iron, aluminum, and magnesium, is decanted from the deposit, and a small excess of ammonia added, which precipitates iron and alumina. To the filtrate is added an excess of sulphuric acid; the precipitate, consisting of strontium, barium, and calcium sulphates, is washed repeatedly by decantation with water containing from 1 to 2 per cent. of sulphuric acid, and finally with distilled water. This will remove all traces of magnesium and calcium sulphate. The precipitate is next treated in the cold with an excess of a solution of ammonium or potassium carbonate (1 to 10), stirring frequently for two days, and finally washing with distilled water by decantation. The mixture of carbonate and sulphate is treated with diluted hydrochloric acid, which dissolves strontium carbonate and traces of baryta. After allowing it to stand for twenty-four hours the clear liquid is decanted and filtered through a filter previously washed with diluted hydrochloric acid. To the perfectly clear filtrate are added 200 Gm. of hydro-

chloric acid per liter, and then from 2 to 3 Gm. of precipitated strontium sulphate, which may contain barium sulphate; stirring frequently for several hours. The strongly acid liquid dissolves a little strontium sulphate (about 0.25 per cent.), but in proportion as the strontium is dissolved the barium takes hold of the sulphuric acid, while an equivalent quantity of strontium chloride is formed. The strontium sulphate being in excess will insure the final elimination of all the barium. The filtrate is evaporated to dryness, the salt dissolved in three times its weight of distilled water, allowed to stand for twenty-four hours, filtered, evaporated to crystallization, and dried. The crystals showed in the spectroscope only the lines of strontium. (*Bull. Soc. Chim.*, 1892, 104.)

Strontium nitrate is largely used for making red fire in pyrotechnics; the salt is made by dissolving strontium carbonate in diluted nitric acid, evaporating the solution and crystallizing.

In 1890, J. V. Laborde demonstrated that the traditional belief in the toxicity of the salts of strontium was incorrect. He found that fifteen grains intravenously given to a medium-sized dog produced no effect whatever, and that large quantities of the strontium salts might be mixed with the food of the animal without disturbing the general nutrition, the strontium salts being less harmful than the corresponding salts of potassium. Indeed, he asserts that during the administration of the strontium the animals gained in health and weight, and, further, that the eliminated strontium in the fecal and urinary discharges had a distinct beneficial antiseptic influence. It is stated that Vulpian in 1885 announced the value of strontium salts, but certainly to Laborde belongs the honor of first establishing their usefulness.

STROPHANTHINUM. U. S.

STROPHANTHIN

(strô-phan-thĩ-nũm)

"A glucoside, or mixture of glucosides, obtained from *Strophanthus*. It should be kept in well-stoppered, amber-colored vials." *U. S.*

Strophantine, *Fr. Cod.*; Strophanthin, *G.*

Preparation.—Strophanthin¹ was made official in the *U. S. P.* (8th Rev.). It may be made by Fraser's process by depriving the ground seeds of fatty oil by percolation with

petroleum benzin, making a tincture from the marc with 70 per cent. alcohol, distilling, evaporating and treating the extract with water, this solution is then filtered and the filtrate precipitated with tannic acid; the precipitate is washed, mixed with litharge, dried and exhausted with alcohol; by adding ether to the alcoholic liquid, strophanthin is precipitated. (See *Strophanthus*, below.)

Properties.—It is officially described as a "white or faintly yellowish crystalline powder, containing varying amounts of water of crystallization, which it does not lose entirely without decomposition. Taste intensely bitter; great caution should be used in tasting it. Permanent in the air. It is very soluble in water and in diluted alcohol, less soluble in absolute alcohol, but nearly insoluble in ether, chloroform, and benzene. When heated, it begins to fuse at 170° C. (338° F.), and is not completely melted until the temperature of 190° C. (347° F.) is reached. Its solutions are dextrogyrate, and neutral to litmus paper. Sulphuric acid produces with Strophanthin an emerald-green color, changing to brown. If to an aqueous solution of Strophanthin a trace of ferric chloride T.S. and a few Cc. of sulphuric acid be added, a red-brown precipitate will be produced, turning dark green after one or two hours. Strophanthin should not reduce alkaline cupric tartrate V.S.; if its solution be heated to 70° C. (158° F.) with a small amount of diluted hydrochloric acid (1 in 20), it will be decomposed into strophanthidin, which precipitates, and a sugar, which will remain in solution, and which will reduce alkaline cupric tartrate V.S." *U. S.*

Uses.—On account of the great variability of strophanthus seeds, strophanthin, which fully represents their therapeutic activities, should always be preferred to the crude preparations of the drug. It is best administered in the form of granules. Stahr affirms (*Th. M.*, 1898, xii.) that three-tenths of a grain (0.020 Gm.) may be safely administered in twenty-four hours.

Dose, one two-hundredth of a grain (0.0003 Gm.).

STROPHANTHUS. U. S. (Br.)

STROPHANTHUS

(strô-phan-thũs)

"The ripe seed of *Strophanthus Kombé* Oliver (Fam. *Apocynaceæ*), deprived of its long awn." *U. S.* "The dried ripe seed of *Strophanthus Kombé*, Oliver, freed from the awns." *Br.*

Strophanthi Semina, Br.; Strophanthus Seeds; *Strophantus, Fr. Cod.*; Semen *Strophanthi, P. G.*; *Strophanthussamen, G.*; *Strofanto, It.*; *Estrofanto (Semilla de), Sp.*

According to Engler and Prantl, there are twenty-eight recognized species of the genus found in Africa and Asia, extending to China,

¹ E. Merck & Co. have sent into commerce, under the name of *G. Strophanthin crystallatum*, a crystalline glucoside obtained from the seeds of *S. gratus*. This occurs in colorless satiny, quadratic, tabular crystals, easily soluble in hot water, soluble in 100 parts of water at 15° C., in 30 parts of absolute alcohol, difficultly soluble in acetic ether, ether and chloroform. The solution of 0.01 Gm. in 1 Gm. of water poured on concentrated sulphuric acid gives it a rose-red color while the aqueous solution assumes a dirty green color. It loses 20 per cent. of moisture at 105° C. and the dried glucoside melts at 187° to 188° C.

the East Indies, and the Philippines. The commercial drug is often largely composed of the seeds of other than the recognized official species, and may contain the seeds from related genera, especially those of *Kickxia africana*, Benth.¹ The seeds of all the species of strophanthus apparently possess, however, hairs that have a characteristic thickened base somewhat resembling those of *nux vomica* seeds. The seeds of various species of the genus *Strophanthus* are used for the preparation of arrow poison in Africa, at Kombé in the Manganja country, in the Gaboon district, and in Guinea and Senegambia. In Gaboon this poison is called *inée*, *onaye*, or *onage*. The plant which yields the arrow poison of Kombé was first brought to Europe by Sir John Kirke and described as a new species by Oliver of Kew, under the name of *S. Kombé*. There can be no doubt that much of the *Strophanthus* of commerce is yielded by other species. *S. Kombé* grows solely in East Africa, as far as is known, so that all of the drug coming from West Africa must be yielded by other species. The tracing of the origin of the seeds is made more difficult by the fact that in Africa seeds from different regions are mixed before shipment. The seeds of *S. hispidus* enter commerce, as do also those of *S. glaber*, *S. emini*, and *S. courmontii*. (*P. J.*, lxiii. p. 321.) A white woolly *Strophanthus* is said to be yielded by *S. Nicholsoni*, a species first characterized by Holmes (*P. J.*, lix. 208). *S. gratus* of Sierra Leone also contributes its seeds; also *S. glaber* contains *ouabain*, which, according to Karsten, is identical with strophanthin. (*C. R. A. S.*, cxvii. 346.)

S. hispidus when by itself takes the form of a bush, but usually occurs as a woody climber inhabiting the forests between the coasts and the centre of the African continent. It reaches to the tops of the highest trees, coiling on the ground, and hanging in festoons from tree to tree. The stem is several inches in diameter. The flowers are cream-colored, yellow at the base, purplish-spotted above. They are grouped in terminal cymes. The lobes of their gamopetalous corollas are prolonged into very narrow tail-like ends, nine or more inches in length. They last but a short time during the months of October and November. The fruit, a pair of foliicles from 10 to 17 inches long, is ripe in June, and is gathered by the natives, who scrape off the husks (epicarp and mesocarp) before drying, and preserve the more leathery internal inner covering (endocarp) with the

enclosed seeds; hence the pods as they appear in commerce are smooth and of a tawny color. The seeds themselves are covered with long comose hairs, which, being deciduous, are apt to be lost before the escape of the seed from the pod. In preparing the arrow poison, the natives are said to pound the seeds deprived of their hairs to a pulp, add the adhesive sap of another plant, and simply smear the mixture for six inches along the point of the arrow. Game wounded by such an arrow is said to be rarely able to move a hundred yards, and the flesh is eaten without bad effect. Karsten has examined the root of *Strophanthus hispidus* and found that it contained *trigonelline*, *choline* and *strophanthin* in such small proportions that it will probably never be commercially valuable. (*B. P. G.*, 1902; 12, 241.)

Strophanthus occurs in commerce either in pods or as clean seeds. Helbing states (*P. J.*, March, 1887) that he has found the seeds to constitute about 37 per cent., the pod (endocarp) 37 per cent., and the hairs about 25 per cent., and says that the quality of the pods may be determined by examining the color of the pappus. If this is white and bright, the seeds and pods are in good condition.

At present (1905) strophanthus seeds are much less mixed than formerly.¹ There are two chief varieties. The official commands a much higher price than does the inferior variety, composed of the seeds of *S. hispidus*.

Official strophanthus seeds are from one and one-half to two and one-half Cm. long, and from four to five Mm. broad. They are more or less rounded off at the base, without, however, losing the distinctly pointed shape; towards the upper end they become suddenly very much narrower, and end in the stalk of the pappus, which stalk is usually not apparent. They are flattened at the sides, and have a much more prominent keel-shaped ridge on one side than on the other; the seed is twisted slightly in the form of a spiral from the base to the apex. This twist is, however, often not very apparent. The color of the seeds varies from a grayish green to a brown, when the fine

¹ In 1892 Hartwich classified commercial strophanthus seeds (*A. Pharm.*, 1892, 401), in the following groups: (1) The official products yielded by *S. hispidus* or *S. Kombé*, which contain strophanthin and no crystals of calcium oxalate. (2) Those resembling the official seeds, but of different habitat,—viz., Mozambique and Sierra Leone. (3) Those which contain calcium oxalate crystals, but no strophanthin,—viz., Senegal, Lagos, Niger, German East Africa, Togoland, and Baol of Senegal. (4) A very hairy seed from the Upper Niger. The hairs vary in color from a silky white to brown; the embryo contains calcium oxalate crystals, but the seeds do not contain strophanthin. (5) Seeds which are said to be glabrous, but possess hairs in the region of the raphe. These include those from Lagos and Zambesi, and contain neither calcium oxalate crystals nor strophanthin. In 1896 S. E. Jefflie stated that there are in the American market two hairy seeds, the product respectively of *S. hispidus* (Kombé) and *S. asper*, and one smooth seed, *S. gratus* of the Gaboon. (*Sec. D. C.*, 1896, 101.) The seeds of *S. gratus* are recommended by E. Glig as more easily recognized than the others and because it yields strophanthin more readily in crystalline form. (*B. P. G.*, 1904, 90.)

¹ The seeds of *Kickxia africana* are without hairs, spindle-shaped, not flattened, twisted into an S-like shape, and with the base and the point of the seed alike in their forms. On cross-section the cotyledons are seen much folded, while those of the strophanthus lie parallel one upon the other. The transverse section of the *kickxia* seed, when treated with concentrated sulphuric acid, first turns brown, then red, while the seeds of both kinds of strophanthus take on a green color. According to Stapf the plant represents a new genus and should be known as the *Funtumia africana*; the only other species of the genus, *F. elastica*, yields India rubber.

hairs have been rubbed off. The hairs are silky, not more than 1 Mm. long. The seeds¹ are officially described as "of a light fawn-brown color, with a distinct greenish tinge; about 15 Mm. long and 4 to 5 Mm. wide, 2 to 2.5 Mm. thick, lance-ovoid, obtuse at the base, gradually acuminate and somewhat acute at the summit, usually twisted, bearing on one side a ridge running from about the centre to the apex; silky-lustrous from a dense coating of closely appressed hairs, which mostly lie in longitudinal grooves on the surface; fracture short and somewhat soft, the fractured surface whitish and oily; kernel consisting of a thin endosperm enclosing straight cotyledons; odor slight, or heavy when the seeds are crushed and moistened; taste very bitter. The endosperm, and often parts of the cotyledons, quickly assume a green color when crushed or cut and treated with concentrated sulphuric acid. Under the microscope the hairs are seen to be of a light greenish-brown color, 1 Mm. or less in length and to consist of but one thin-walled cell. A decoction prepared with 1 part of the seed and 10 parts of water has a brownish color, and is not changed in appearance on the addition of iodine T.S., ferric chloride T.S., or mercuric potassium iodide T.S." *U. S.*

The seeds of *S. hispidus* are of a pure brown color, with the hairs very inconspicuous and the keel consequently very prominent. They are distinctly smaller than those of *S. Kombé*, being about one Cm. long and one and a half to two Mm. broad. The stalk of the pappus is usually very evident. They are not longitudinally grooved but are often wrinkled on the surface more or less lengthwise.

The more important of the rarer varieties of strophanthus are composed of seeds which at one time were much mixed in Africa before exportation with those of *S. Kombé* and *S. hispidus* and are the products of two species, *S. glabra* and *S. Thalloni*. The seeds of *S. glabra* are about thirteen to sixteen Mm. long from three to four and a half Mm. wide, and from one to one and a half Mm. thick. They are lanceolate with a rounded or truncated base and a long attenuate apex. The ventral face is flat or concave, the dorsal being convex, and possesses sometimes a small keel near the shaft. The surface is glabrous, of a dull waxy appearance; the color varies from an ochre-yellow to a fawn or cinnamon; the odor is characteristic; the fracture is horny and the taste extremely bitter. The hairs of the awn are about seven Cm. in length, numerous, silky, white, and when viewed in a mass yellowish or grayish. The seed coat is relatively thin; the albumen is thick and cartilaginous; the embryo is not thick, the radicle is as long as in *S. hispidus* or *S. Kombé*. With concentrated sulphuric acid the color changes from yellow to rose and finally to violet.

The seeds of *S. Thalloni* are very long and narrowly spindle shaped tapering above and below, and covered with numerous brownish hairs. A smooth blackish-brown *Strophanthus* seed is said to be sent into commerce from Indo-Malaya.

The seeds of *S. Courmontii* are 8 to 14 Mm. in length, 2.5 to 3.5 Mm. in breadth and 1 to 2 Mm. in thickness; of a distinctly lanceolate form and decidedly brown color, often with the hairs rubbed off, but having a golden sheeny appearance when these remain, while the tint is dull and reddish when they are absent. The ridge on the ventricular surface is indistinct and the arrangement of the hairs in longitudinal rows is not as apparent as in the official seed. They also contain crystals of calcium oxalate in abundance, which have been stated by some observers to be entirely absent from *S. Kombé* and *S. hispidus* but are in fact there in very small amount. The seeds of *S. elemi* are grayish green in hue and contain crystals of calcium sparingly in the embryo. The statement of E. M. Holmes (*P. J.*, lxiv.) that the seeds of *S. Kombé* and *S. hispidus* give with sulphuric acid a greenish reaction, while those of *S. Courmontii* give a reddish, and *S. elemi* a yellowish brown changing into reddish, seems not be absolutely accurate, for while the seed albumen of *S. Kombé* always gives the greenish reaction the cotyledons frequently are mottled with red and rarely give an entirely red reaction. (Perredes.)

The Qualitative Examination of Strophanthus Seeds.—C. Hartwich (*A. Pharm.*, 1892) declares the usual course for the qualitative examination of strophanthus seeds—as the external appearance, the bitter taste, and the few chemical tests—insufficient, and recommends a microscopical test for strophanthin to supplement the usual tests. In the examination of a great variety of strophanthus seeds some were found to contain starch, which is contrary to the general opinion.

For the valuation of the seeds the presence of strophanthin should be ascertained in the following manner. A fine cross-section of the seed is placed on a glass slide and covered with a drop of concentrated sulphuric acid. The endosperm at least should assume an intense green color, which is easily seen with a hand-glass. Often the green is preceded momentarily by a blue color. The cotyledons are also colored green, but generally less intensely than the endosperm. Gradually the color changes through blue into red, and after one-quarter to one hour it disappears. In seeds which contain but little strophanthin the endosperm alone is colored green, while the embryo is colored yellow and then red, or only the epidermis and the adjacent cells are colored in addition.

Tests for Tincture and Extract of Strophanthus.—For testing the tincture three drops are taken, and for the extract a piece a little larger than a pin head. In either case mix the drug

¹ For an elaborately illustrated article on the histology of *S. Kombé*, by P. E. F. Perredes, see *W. C. R. L.*, No. 15; see also *B. P. G.*, 1904, 104, 120.

with a half-drop of ferric chloride solution and three drops of sulphuric acid. A brown precipitate is formed which is distinctly green after one hour, and should retain the color for fully three hours.

Hardy and Gallois have obtained from strophanthus two crystalline principles. One, which is a glucoside, they call *strophanthin*; the second, an alkaloid, they name *inaïne*. The first-named appears to be the active principle of the poison. (*J. P. C.*, 3e sér., xxv. p. 176.) T. R. Fraser describes more fully the glucoside strophanthin. (*P. J.*, 1886, July 23.) When heated with dilute sulphuric acid it yields glucose and *strophanthidin*, which is insoluble in water, is very soluble in alcohol, and has a strongly bitter taste. *Strophanthin* is a white crystalline powder, neutral in reaction, intensely bitter, freely soluble in water, less so in rectified spirit, and nearly insoluble in ether and chloroform. According to E. Merck it fuses at 185° C. Fraser has since (*A. J. P.*, 1889, p. 532) further investigated strophanthin. He found it difficult to separate, but obtained it pure by a somewhat tedious process, depending upon the formation of a tannate and subsequent decomposition by lead oxide. It yielded upon analysis results corresponding to the formula $C_{20}H_{34}O_{10}$. Thoms (*Ber. d. Chem. Ges.*, 1898, 534) obtained pure strophanthin. Arnaud gives its formula as $C_{31}H_{48}O_{12}$; this was confirmed by Kohn and Kulisch. Feist gives its composition as $C_{40}H_{66}O_9$. Thoms found that the strophanthins as obtained from different species differ somewhat in chemical composition and properties and he proposes to designate them as follows: *k-strophanthin* when obtained from *S. Kombé*; *g-strophanthin* (*S. gratus*), *e-strophanthin* (*S. Eminé*), *h-strophanthin* (*S. hispidus*). To *g-strophanthin* he gives the formula $C_{30}H_{46}O_{12} + 9H_2O$. *Strophanthidin* has the formula $C_{26}H_{38}O_7 + 1\frac{1}{2}H_2O$. *Strophanthidin*, the product of decomposition of the glucoside, is described as having an intensely bitter taste and a neutral reaction, and as being very slightly soluble in water, moderately soluble in cold and freely in warm alcohol. It crystallizes with great readiness. No alkaloid was detected, but in the lead precipitate from an aqueous solution of the alcoholic extract a compound was found of strongly acid reaction and freely soluble in water, to which the name of *kombic acid* has been given. The experiments of Fraser have shown that the active principle of strophanthus is most abundant in the seeds, but that it is contained also in the follicles and the hairs. Pharmaceutical preparations of the drug should, therefore, be made from the separated seeds, while the pericarp and the hairs may be employed for the manufacture of strophanthin. For methods of assaying strophanthus see *D. C.*, 1900, 132.

Uses.—The first experiments with the *Kombé* arrow-poison were those of Thomas R. Fraser. (*J. A. P.*, vii. 141.) One-twentieth of a grain of the extract of the seeds produced in the frog

stiffness of the limbs, gradual loss of reflex sensibility, arrest of the heart in systole, and, after a time, complete loss of voluntary movement,—the respiration continuing for a length of time after the cessation of the heart's beat. The loss of voluntary movement and the cessation of respiration appear to be due to a direct action of the poison upon the muscles themselves. The first influence of the poison upon the muscular fibre is to increase its tonicity, and when the muscle dies it does not go into relaxation, but passes directly from life into post-mortem rigidity. The drug seemed to exert little or no influence upon the spinal cord or the nerve trunks.

These experiments have been abundantly confirmed by subsequent observers, so that it is fairly established that the *Kombé* arrow-poison is essentially a muscle poison, and that it acts upon the muscles of the heart as it acts upon other muscles, only more vigorously. In some cases, especially in mammals, death occurs through respiratory paralysis, and not through cardiac arrest,—the respiratory muscles in these cases feeling the influence of the poison more powerfully than the heart. The value of the drug in practical medicine depends chiefly upon its heart action, moderate doses of it producing in both man and the lower animals pronounced rise of the blood pressure. It is probable that the muscles in the arterioles feel the effect of the drug, and by their contraction help in the elevation of the arterial pressure, although this is not proved, and Fraser believes to the contrary.

In man, the effect of full therapeutic doses of the drug is to lower the pulse from ten to thirty beats, increasing at the same time its force and volume, usually without producing other symptoms, unless it be increased diuresis. The effect upon the pulse comes on much more quickly and is much less permanent than that of digitalis, lasting usually from four to eight hours. The diuretic action of the drug seems to depend not only on its effect upon the circulation, but also largely on a direct influence upon the secreting structure. Only one case of doubtful cumulative action has as yet been reported (see H. C. Wood's *Therapeutics*), and it is probable that the active principle is both rapidly absorbed and rapidly and completely eliminated. *Strophanthus* is of great value in practical medicine in the same class of cases in which digitalis is employed. (See *Tinctura Strophanthi*.) It seems to be superior to digitalis as a diuretic, and therefore is especially indicated in *cardiac dropsy*. *Strophanthus* is locally irritating, and in some cases even therapeutic doses produce violent gastric pain and vomiting. Local anæsthetic properties have been claimed for strophanthin by Panas, by Gley, by Hare and De Schweinitz, and by other observers. The irritating effects of strophanthin are, however, too great for its practical use, and it has been especially shown by Hare and De Schweinitz that the drug when

placed in the eye is exceedingly prone to produce violent inflammation and even ulceration of the cornea.

Strophanthin is now used in medicine, but great caution is necessary in its employment, on account of its extreme activity (Fraser found that a solution of 1 part of strophanthin in 6,000,000 would stop the frog's heart) and the present absolute uncertainty as to the proper dose, growing out of its varying impurity. Rothziegel and Koralzewski maintain, however, that the active principle is more prompt and certain in its influence, and less apt to disturb the stomach, than are the ordinary preparations of the drug. They give the dose as from 1-300th to 1-200th of a grain (0.0002 to 0.0003 Gm.), and have in some cases administered as much as one-sixteenth of a grain (0.004 Gm.) during twenty-four hours. When the alkaloid is given hypodermically the effect on the pulse is said to be manifest in five minutes. *Strophanthin tannate* contains 58.14 per cent. of strophanthin, and is given in the dose of from one-hundredth of a grain to one-sixtieth of a grain (0.0006 to 0.001 Gm.).

As the amount of strophanthin varies in true strophanthus seeds from 0.45 to 1 per cent. (Rice), it is plain that such preparations as tincture and extract must very greatly vary in their activity, even when carefully made from the drug. If it were possible to practically assay these preparations, the Pharmacopœia should direct only assayed preparations; but at present there seems to be no practical method known. In experiments made by H. C. Wood and W. S. Carter the extract of strophanthus prepared by evaporating the official tincture was found to be as uniform and effective in its action as the tincture itself. Strophanthin is now official and is preferable to the older preparations. (See *Strophanthinum*.)

Dose, of strophanthus, one-half to two grains (0.032 to 0.13 Gm.).

STRYCHNINE

(stryčh-nīnā)

$C_{21}H_{22}N_2O_2 = 331.73$

"An alkaloid obtained from *Nux Vomica*, and also obtainable from other plants of the *Loganiaceæ*." *U. S.* "An alkaloid, $C_{21}H_{22}N_2O_2$, obtained from the dried ripe seeds of *Strychnos Nux-vomica*, *Linn.*, and other species of *Strychnos*." *Br.*

Strychnia, U. S. 1870; *Strychninum; Strychnine, Fr. Cod.*; *Strychnin, G.*; *Strichenina, It.*; *Estricnina, Sp.*

The U. S. and Br. Pharmacopœias very properly omit processes for preparing this alkaloid, as it can be made profitably only by the manufacturing chemist on a large scale. (See *U. S. D.*, 17th ed., p. 1295.)

The bean of *St. Ignatius* yields strychnine more easily and more largely than *nux vomica*.¹ If thought desirable, brucine may be in great measure separated from the strychnine of commerce, by dissolving the latter in very dilute nitric acid, filtering, and concentrating. Brucine nitrate crystallizes in short, thick, dense prisms grouped together; strychnine nitrate in radiated tufts of long, light, capillary needles. By gentle agitation with the liquid, the latter salt is suspended and may be poured off, leaving the former. The alkaloids may be obtained by dissolving the salts in water, and precipitating with ammonia.

Properties.—As usually found in commerce, strychnine is a white or grayish-white powder. When rapidly crystallized from its alcoholic solution, it has the form of a white, granular powder; when slowly crystallized, that of elongated octohedra, or rhombic prisms with pyramidal summits. It is officially described as in "colorless, transparent, prismatic crystals, or a white crystalline powder; odorless, and having an intensely bitter taste, perceptible even in solutions of 1 in 700,000. *Strychnine should be tasted with extreme caution.* Permanent in the air. Soluble in 6400 parts of water, 110 parts of alcohol, 5500 parts of ether, 6 parts of chloroform, 150 parts of benzene, and in 180 parts of amyl alcohol at 25° C. (77° F.); soluble in 3000 parts of water at 80° C. (176° F.), and in 28 parts of alcohol at 60° C. (140° F.). Its melting point is 268° C. (514.4° F.). Upon ignition it is consumed, leaving no residue. Its solutions are lœvogyrate and alkaline to litmus paper. Sulphuric acid containing 1 percent. of ammonium vanadate produces with Strychnine a deep violet-blue color, changing to a deep purple, and finally to a cherry-red. Sulphuric acid containing a trace of potassium iodate produces a violet color, changing momentarily to reddish-purple. If 0.1 Gm. of Strychnine dissolved in a few drops of nitric acid be evaporated to dryness, and a few drops of ammonia water added to the yellow residue, an orange color will be produced, which will turn reddish-purple, and finally brown, on the addition of a small amount of alcoholic potassium hydroxide T.S. Sulphuric acid should produce no color (absence of sugar and other readily carbonizable organic impurities), but on adding a fragment of potassium dichromate, a deep blue color is momentarily produced, changing to deep violet, then to purplish-red, cherry-red, and finally to orange or yellow. Nitric acid, when added to a crystal of Strychnine on a white porcelain surface, should not produce more than a faintly pink color (limit of brucine)." *U. S.* "Trimetric

¹ J. F. Molyn proposed, previously to the extraction of strychnine, to subject *nux vomica* to fermentation, by which the saccharine and gummy matters of the seeds are decomposed, and lactic acid is formed, which decomposes the strychnine and brucine igasurates, producing with these bases very soluble lactates. For the particulars of this process see *A. J. P.* (xix. 99), and for other processes see *U. S. D.*, 14th ed., p. 1456.

prisms; colorless and inodorous; very sparingly soluble in *water*, but communicating to it an intensely bitter taste; soluble in 150 parts of cold but in less of boiling *alcohol* (90 per cent.), and in 6 parts of *chloroform*; slightly soluble in cold *absolute alcohol*, but readily in 40 parts of boiling *absolute alcohol*, and nearly insoluble in *ether*. Sulphuric acid forms with it a colorless solution, which on the addition of *potassium bichromate* acquires an intensely violet hue, speedily passing through red to yellow. When *sulphuric acid* containing one-two-thousandth part of *potassium permanganate* is brought into contact with a minute particle of Strychnine, a violet coloration results. Not colored by *nitric acid* (absence of brucine); leaves no ash when burned with free access of air (absence of mineral impurities).¹ Br. It melts like a resin, is decomposed at a comparatively low temperature, and entirely dissipated at a red heat. Guy obtained a crystalline sublimate, at a heat but a few degrees below that at which it begins to change color and undergo decomposition. Its melting point has been given as 284° C. (543° F.), but, according to Flückiger, in small portions it melts as low as 225° C. and can with care be sublimed without decomposition. According to Waddington, when heated to decomposition it emits a most suffocating odor, resembling the odor of asphaltum. (P. J., March, 1868, p. 413.) Fused with an excess of potassium hydroxide, it yields, according to Goldschmidt (Ber. d. Chem. Ges., 15, p. 1977), *indol*, C_8H_7N , and when distilled with zinc dust it yields a *dimethyl pyridine*, C_7H_9N , and *carbazol*, $C_{12}H_9N$. The volatile oils dissolve it freely. Petroleum benzin dissolves 0.607 per cent. of it, and amyl alcohol 0.55 per cent. (Dragendorff, J. P. C., 4e sér., iv. 473.) It has an alkaline reaction on test-paper, and forms salts with the acids. Nitric acid does not redden it if perfectly pure, but almost always reddens it as found in commerce, in consequence of the presence of brucine. Eugène Marchand proposed the following test by which a very minute proportion of strychnine may be detected. If a little of the alkaloid be rubbed with a few drops of concentrated sulphuric acid containing one-hundredth of nitric acid, it will be dissolved without change of color; but if the least quantity of lead peroxide be added to the mixture, a magnificent blue color will be instantly developed, which will pass rapidly into violet, then gradually to red, and ultimately become yellow. (J. P. C., 3e sér., iv. 200.) Otto recommended as a test a minute quantity of solution of potassium dichromate, which, added to the solution of strychnine in concentrated sulphuric acid, produces a splendid violet color. (A. J. P., xix. 77.) A similar change of color is produced, according to E. W. Davy, by substituting a strong solution of potassium ferricyanide (red potassium prussiate) for that of potassium dichromate. (A. J. P., xxv. 414.) It appears that any substance capable of yielding nascent oxygen readily will serve to develop the

characteristic violet color, when applied after the addition of sulphuric acid. Landerer has found that solid iodic acid or potassium iodate heated gently with strychnine gives rise to a beautiful violet color, gradually passing to red, which remains unchanged for many days. (A. J. P., March, 1861, p. 110.) According to Wm. Copney, the least efficacious agent is potassium chlorate, a much better is lead dioxide, a still better is manganese dioxide, and the best of all is potassium dichromate, and the general result of numerous experiments, recently made, is that the last-mentioned agent is the most effective. The sulphuric acid must be of not less sp. gr. than 1.84. The play of colors, according to Copney, is first blue, then purple, then crimson, which is followed by red and green, the latter sometimes giving place to yellow. It is stated that the 1-500,000th part of a grain may be detected. (See A. J. P., xxviii. 459.) On the other hand, some chemists have found difficulties with the potassium dichromate test. Thus, Brieger (*Jahresb.*, 1850, p. 617) found that, unless the substance was first moistened with sulphuric acid and the dichromate added to it subsequently, the reaction of strychnine was interfered with by quinine, morphine, and especially by sugar. Sonnenschein (*Fresenius's Zeitschrift*, 9, p. 495) found that ceroso-ceric oxide was much more sensitive as a reagent to use with sulphuric acid for strychnine than potassium dichromate. This fact we can confirm from experience. It gives a blue color lasting longer, which then becomes violet, and then a permanent cherry-red.¹ Vanadio-sul-

¹ To succeed in detecting the alkaloid when mixed in small proportion with organic matters, it is necessary first to disintegrate the organic matter, that the action of a solvent of the strychnine should not be impeded, and that the alkaloid should be completely separated from the foreign matter. The process of Rogers and Girdwood, by which these objects are effected, is the following: Digest the substance supposed to contain the strychnine with a mixture of 1 part of hydrochloric acid and 10 of water, until it becomes apparently fluid. Filter, and evaporate the liquid to dryness on a water bath. Treat the residue with alcohol as long as anything is dissolved, filter, and evaporate. Dissolve the residue in water, and filter. Add solution of ammonia in excess to the aqueous solution, and agitate in a bottle or long tube with half an ounce of chloroform. Upon repose the chloroform subsides, holding the alkaloid in solution. Draw it off by a pipette, and evaporate the chloroform over a water bath. Moisten the dry residue with concentrated sulphuric acid, and expose the mixture for some hours to the temperature of a water bath, by which means all the organic matter except the strychnine is decomposed. Treat the charred mass with water, filter, add excess of ammonia, and shake the mixture with a drachm of chloroform. Separate the chloroform as before, and, if the matter left after the evaporation of a small portion of it is charred by concentrated sulphuric acid, the whole of it must be treated in the same manner as the previous chloroform solution. The last chloroform solution obtained is then to be tested for strychnine. Take up a little of it in a capillary tube, and drop it on the smallest space of a warm porcelain dish, so that each successive drop may be evaporated. When the dish is quite cold, moisten the spot with concentrated sulphuric acid, and add a minute fragment of potassium dichromate. Should the characteristic color not be developed, it is said that, if there be the minutest quantity of strychnine present, the color will become visible on adding sulphuric acid rendered slightly yellow by chromium trioxide. In conducting the process, care must be taken not to stir the spot moistened by sulphuric

phuric acid (1 part of ammonium vanadate dissolved in 200 parts of pure sulphuric acid of 1.84 sp. gr.) is colored by strychnine at first violet-blue, passing into violet, and finally cinnabar-red. On dilution with water this color remains rose-red. According to Dragendorff, the color persists when as little as 0.001 milligramme of strychnine is used.

Wm. T. Wenzell states that, when very minute quantities of the alkaloid are being dealt with, much the best plan is to prepare a reagent by dissolving in 2000 grains of sulphuric acid one grain of potassium permanganate. The alkaloid, during the evaporation of its acidulated solution on the porcelain, collects in the margins of the film, and the smallest possible dot of the reagent is to be placed so that its margin comes in contact with that of the film. In this way, Wenzell affirms, he was able to detect

acid with a rod before the addition of the dichromate, and not to expose the spot to a very strong light, which interferes with the chemical reactions. (*M. T. G.*, June, 1857, p. 620.) The process of dialysis may be advantageously applied to the separation of strychnine from the organic matters containing it, when brought to the liquid state. (See *Dialysis*, PART II.) Diluted acetic acid may be used for extracting the alkaloid with other soluble substances from the contents of the stomach.

It is stated by C. W. Bingley that, if much tartar emetic be contained in a solution with a little strychnine, a pale greenish color is produced instead of the violet, and, in like manner, if antimony chloride be present, the sulphuric acid and potassium dichromate test fails altogether. (*Chem. Gaz.*, June 16, 1856, p. 229.) Richard Hagen, having been induced, by the assertion of von Slicherer that this test fails when the strychnine is mixed with tartar emetic or other tartrates, or even tartaric acid, to investigate the subject, ascertained that this statement, as a rule, is erroneous; for the reaction takes place with strychnine or its hydrochloride though mixed with 20 or 30 parts of antimony tartrate; yet when *strychnine nitrate* is used with 20 parts of the antimonial tartrate, the mass almost instantly acquires a green color with the reagents mentioned. But even with strychnine nitrate the test succeeds if lead peroxide is used instead of chromium trioxide as the oxidizing agent. (*Ibid.*, Oct. 15, 1857, p. 398.)

For a particular account of the results produced by the reaction of a large number of substances with strychnine, the reader is referred to a paper by T. G. Wormley, in the *Chem. News* for April 14 and 28, 1860 (pp. 218 and 242). Among other trials made by him was that of the action of this alkaloid on frogs, proposed as a test by Marshall Hall. The poison was injected into the stomachs of the animals through a pipette. A solution containing 1 per cent. of strychnine produced rigidity and violent tetanic spasms immediately, and death in 8 minutes. With 1 part of strychnine to 1000 of the solvent, the spasmodic symptoms were induced in 3 or 4 minutes; with 1 in 10,000, in from 10 to 24 minutes; with 1 in 20,000, and 1 in 30,000, the symptoms were less unequivocal though tetanic spasms were noticed in some of the animals.

Experiments by W. A. Guy on the effects of sulphuric and nitric acids on strychnine and many other alkaloids, published with tabulated results, show that in no one out of 66 proximate principles, chiefly alkaloids, was the same change of color produced as in strychnine by concentrated sulphuric acid, followed by a crystal of potassium dichromate. (See *A. J. P.*, Nov. 1861, p. 517.) In the same number of the same journal (p. 527) is a paper by T. E. Jenkins, giving the result of experiments with sulphuric acid and potassium dichromate on numerous alkaloids, all tending to prove the delicacy and certainty of this color-test of strychnine. A Wynter Blyth distils the suspected alkaloid with a solution of potassium permanganate to dryness, condensing the vapor in a cold flask, and applying Nessler's test for ammonia to the liquid thus obtained. He finds that all the poisonous alkaloids differ, but are individually constant in the amount of ammonia yielded, and that the test can always decide to which class the alkaloid belongs, and often what alkaloid it is. Strychnine yields half its nitrogen, or 5.09 per cent. of ammonia. See also *M. T. G.*, 1875, 1. 387.

1-900,000th part of strychnine. (*A. J. P.*, xlii. 385.) Some doubt was thrown upon the value of this test by experiments which seemed to prove that the presence of morphine in excess, especially in connection with organic matter, so far modified or disguised the action of the test upon strychnine as to prevent the appearance of the characteristic color, but subsequent and carefully conducted experiments by Robert P. Thomas satisfactorily determined that the conclusions in relation to the effects of morphine were erroneous, and that whether alone or associated with organic matters, in small or in large quantity, it does not prevent the operation of this color-test if carefully applied. (*Am. J. M. S.*, Oct. 1861, and 1862, 1340; also *J. Am. C. S.*, 1894, No. 12.) J. U. Lloyd in his novel "Stringtown on the Pike" used in an interesting manner a color reaction which he had discovered that produced a color which might deceive some who were working on a toxicological investigation in strychnine poisoning. *Lloyd's reaction* consists in adding sulphuric acid to a mixture of 1 part of hydrastine and 4 parts of morphine and adding a little potassium dichromate in the manner in which the color test for strychnine is made; colors are produced which somewhat resemble those given by strychnine, but a careful toxicologist could not be deceived. A controversy ensued upon the announcement of the reaction, participated in by Williams, Mayer, Wangerin, Wharton, and others, the result of which proved that the value of the official color test of strychnine had not been seriously assailed. *D. C.*, 1901, 28, 48; *Proc. N. Y. State Pharm. Assoc.*, 1901, 252; *Amer. Drug.*, 1903, 66. Strychnine consists of carbon, hydrogen, nitrogen, and oxygen and has the formula $C_{21}H_{22}N_2O_4$. The salts of strychnine are for the most part soluble and crystallizable. Their solution is decomposed by the alkalies and their carbonates, and by tannic but not by gallic acid, and is not affected by ferric salts. They are precipitated by the solution of iodine in potassium iodide, and the precipitate, though soluble in alcohol, is insoluble in the diluted acetic and hydrochloric acid of the U. S. Pharmacopœia. (Fairthorne, *A. J. P.*, xxvii. 212.)¹

¹ When an aqueous solution of strychnine sulphate and potassium nitrite is boiled, an effervescence takes place, owing to the escape of nitrogen, and the solution becomes yellow. If ammonia is now added, a precipitate takes place, which has been found to consist of two alkaloids, resulting from the oxidation of the strychnine in different degrees. One of these the discoverer, P. Schutzenberger, proposes to name *oxystrychnine*, and the other *dioxystrychnine*. (See *A. J. P.*, March, 1859, p. 133.)

Methyl-strychnine. *Methyl-brucine*.—These alkaloids are formed by replacing one of the atoms of hydrogen in strychnine by methyl (CH_3), which is effected by acting on the alkaloids by methyl iodide. A singular and, if verified, very important statement in relation to these modifications of strychnine and brucine, made by Stahlschmidt (*Ann. Ch. Phys.*), is that they are not poisonous. He gave to a rabbit five grains of methyl-strychnine was afterwards killed in five minutes by one-twentieth of a grain of strychnine placed upon its tongue. The important practical inference is that methyl iodide might be an antidote to strychnine. (See *A. J. P.*, 1860, p. 220.)

Strychnine is likely to contain impurities, of which the chief, besides brucine, are coloring matter and lime or magnesia. The two latter impurities are left behind when the adulterated alkaloid is incinerated in the open air. Pure strychnine leaves no ashes under these circumstances. Brucine is detected by the red color which it yields with nitric acid. Neither this nor sulphuric acid colors strychnine,—a test which distinguishes it from several other alkaloids.

Uses.—The effects of strychnine upon the system are identical in character with those of nux vomica, and it is employed for the same purposes as a medicine. In whatever way strychnine is introduced into the system, it acts, if in sufficient quantity, as a violent poison. The evidences of its slightest action are muscular twitchings and stiffness. After poisonous doses the symptoms usually come on not only speedily but very suddenly. They are convulsions, both tonic and clonic, affecting all the voluntary muscles, plainly reflex in character, and interrupted by periods of usually complete relaxation. Consciousness is undisturbed. The body is during the convulsion rigid, with the face drawn into the *risus sardonius*, the limbs stiffly extended, and the whole person bowed backward in marked opisthotonos. The convulsions are accompanied with pain, and may be so severe as to cause death by locking the chest in a general respiratory spasm. This death during a convulsion may occur very early, and is accompanied by evident signs of asphyxia; if in any convulsion consciousness be affected, it is by approaching asphyxia, and is an evidence of imminent peril. In many instances the patient survives some hours and finally dies of exhaustion.

The best chemical antidote to strychnine is potassium permanganate, which should be freely administered from time to time until a result is reached. Washing out the stomach with a solution of the permanganate is excellent, provided it is done early and the patient anesthetized before any attempt is made. We have seen fatal spasm brought on before the stomach tube reached the œsophagus. The general treatment of strychnine poisoning consists in the maintenance of absolute quiet, and the use of such spinal sedatives as chloroform, amyl nitrite, opium, chloral, and potassium bromide; tobacco, aconite, and various similar sedative substances have been used, but no drug which acts powerfully as a cardiac depressant should be employed. Chloroform and amyl nitrite act very promptly, but their impression is fugacious, and their use should be restricted to the arresting of convulsions so severe as to threaten life. Opium may be given in moderate doses, and very large doses of cannabis Indica have been employed in some cases with excellent results, but, as it exists in our markets, this drug is too uncertain for any reliance to be placed upon it. Potassium bromide and hydrated chloral are exceedingly valuable remedies. In any case of severe strychnine poison-

ing it would be advisable to begin the general medicinal treatment with the administration of half an ounce (15.5 Gm.) of potassium bromide. After this hydrated chloral may be given in from twenty- to thirty-grain (1.3 to 2.0 Gm.) doses, at intervals of greater or less length, according to the severity of the symptoms, inhalations of chloroform, ether, and amyl nitrite being practised *pro re nata*, and the bromide also being repeated in much smaller dose if it seems advisable.

Ether acts too slowly to be comparable in its effects to chloroform in this toxæmia, but it must not be forgotten that chloroform is alleged to have produced sudden cardiac death in strychnine poisoning, and in the latter stages, when exhaustion has set in, ether certainly is the safer remedy; under these circumstances alcohol should be freely administered, as tending not only to quiet spasm, but also to sustain the heart's action.

In an investigation of the members of the pyridine series of bases by C. Greville Williams and W. H. Waters (*Proc. Roy. Soc.*, xxxii. p. 162, 1881), they found that β lutidine (dimethyl-pyridine, C_7H_9N) was antagonistic to strychnine and an apparent antidote. When injected into frogs already under the influence of strychnine, it arrested the convulsions; or if given first and then followed by a fatal dose of strychnine, it prevented the appearance of the tetanus. (Blyth, *Poisons, their Effects and Detection*, 1884, p. 319.)

The chief physiological action of strychnine is stimulation of the motor and vasomotor centres of the cord; the peripheral nerves are affected only by very large toxic doses, which exert both a direct and an indirect sedative influence upon them. The diagnosis of strychnine poisoning from tetanus, hysteria, and other convulsive diseases is to be determined by the jaw being affected after the limbs and trunk, the relaxation between the convulsions, the universality of the latter, the retention of consciousness, the rapidity of the attack, and the history of the case.

On account of its stimulant effect upon the gastric mucous membrane, and of its tendency to excite the vasomotor and motor centres of the spinal cord and thereby increase the activity of the circulation and the general systemic tone, strychnine is a very valuable tonic, which may be given along with iron and simple bitters in *anæmia*, and especially in cases of general relaxation. Its striking convulsive influence early led to its use in *palsies*, and it is habitually so employed today. As, however, the loss of muscular power in these cases is very rarely due in chief part, if at all, to depression of the spinal centres, it is not common to see any very marked result from the use of the drug. In *infantile palsies* and other affections in which the nutrition of the muscles is largely at fault, the injection of strychnine into the affected muscles is sometimes productive of great good.

As a respiratory stimulant strychnine is very valuable in *subacute* and *chronic bronchitis*, especially in old and feeble subjects, in advanced *adynamic pneumonia*, in *chloral*, *opium*, and other *narcotic poisoning*, and in the accidents of *anæsthesia*, when death is threatened from respiratory failure. In these cases it must be given in large doses, and, when the symptoms are urgent, hypodermically. In certain forms of circulatory failure and *shock* it is very commonly employed. In *heart diseases* it is usually inferior to digitalis, but may be used with benefit in fatty *myocarditis*.

Strychnine, owing to its tendency to increase the activity of non-striated as well as of striated muscular fibres, is a valuable addition to laxative medicines where there is reason to suspect relaxation of the muscular coat of the bowel. By the oculists strychnine is much used in *atrophy of the optic nerve*. The dose of strychnine varies very greatly according to the effect desired. As a simple tonic from 1-40th and 1-30th of a grain (0.0016 to 0.002 Gm.) may be given three times a day. As a stimulant in low diseases, in certain affections of the spinal cord, in chronic heart disease, and in the *adynamic* nervous conditions of chronic alcoholism, etc., much larger amounts may be given with great advantage. Very large doses should be given hypodermically from four to six hours apart, and be ascended to rather than commenced with. In this way an amount of even three-fourths of a grain (0.048 Gm.) of strychnine a day may be reached.¹

Dose, one-sixtieth to one-thirtieth of a grain (0.0011 to 0.002 Gm.).

STRYCHNINÆ HYDROCHLORIDUM. Br.

STRYCHNINE HYDROCHLORIDE [Hydrochlorate
of Strychnine, *Brit. Pharm.* 1885]
(stryċh-nī'næ hÿ-dro-ċhlō'rĭ-dŭm)

"The hydrochloride of an alkaloid obtained from *Nux Vomica* and from other species of *Strychnos*." *Br.*

Strychninum Hydrochloricum; Chlorhydrate de Strychnine, *Fr.*; Strychninhydrochlorid, *Salzsaures Strychnin*, *G.*

¹ Strychnine should never be prescribed in liquid form in combination with bromides, iodides, or chlorides, for fear of forming the insoluble strychnine hydrobromide, hydriodide, or hydrochloride. Several cases of poisoning have occurred through neglect of this precaution. A. B. Lyons (*A. J. P.*, Oct. 1877) records a case of poisoning through the patient's receiving in the last dose the greater portion of the strychnine hydrobromide, which had crystallized out.

This salt of strychnine was made official for the first time in the *Br. Ph.* 1898; it is used in making *Liquor Strychninæ Hydrochloridi*. (See p. 739.) It is described as in "small colorless trimetric prisms which readily effloresce in the air; soluble in 35 parts of *water* or in 60 parts of *alcohol* (90 per cent.), forming a solution which is neutral to *litmus* and intensely bitter to the taste. The salt should afford the reactions characteristic of hydrochlorides, and should respond to the qualitative tests mentioned under 'Strychnina,' but should not yield any characteristic reaction for sulphates. Dried at a temperature of 212° F. (100°C.) it should lose from 7.3 to 8.8 per cent. of moisture." *Br.*

In its physiological and therapeutic action, strychnine hydrochloride is equivalent to strychnine though slightly weaker.

Off. Prep.—*Liquor Strychninæ Hydrochloridi*, *Br.*

STRYCHNINÆ NITRAS. U. S.

STRYCHNINE NITRATE
(stryċh-nī'næ nī'trās)

"The nitrate [$\text{NO}_2\text{OH}\cdot\text{C}_{21}\text{H}_{22}\text{N}_2\text{O}_2$] of the alkaloid Strychnine. It should be kept in well-stoppered vials." *U. S.*

Azotate de Strychnine, Fr. Cod.; Nitrate de Strychnine, *Fr.*; Strychninum nitricum, *P. G.*; Strychnin-nitrat, *Salpetersaures Strychnin*, *G.*; Nitrato di stricnina, *It.*

Preparation.—This salt may be made by dissolving a sufficient quantity of the alkaloid strychnine in diluted nitric acid until it is neutralized, evaporating the solution and crystallizing the strychnine nitrate.

Properties.—It is officially described as in "colorless, glistening needles; odorless, and having an intensely bitter taste. *Strychnine Nitrate* should be tasted with extreme caution. Permanent in the air. Soluble in 42 parts of water, 120 parts of alcohol, 156 parts of chloroform, and in 60 parts of glycerin at 25° C. (77° F.); soluble in 8 parts of water at 80° C. (176° F.), and in 60 parts of alcohol at 60° C. (140° F.); insoluble in ether. When heated, the salt decomposes, but it does not melt, and when ignited it is consumed without leaving a residue. Its aqueous solutions are neutral to litmus paper, and levogyrate. A solution of the salt, when poured carefully into a test-tube upon a layer of sulphuric acid containing in solution a little diphenylamine, will develop a blue zone at the juncture of the two liquids. On being heated with hydrochloric acid a bright red color is formed. Sulphuric acid containing 1 percent. of ammonium vanadate produces with Strychnine Nitrate a dark violet-blue color, changing to purple, and then to red. Sulphuric acid containing a trace of potassium dichromate produces momentarily a blue color,

changing to violet, then to purplish-red, cherry-red, and finally to orange or yellow. If 0.1 Gm. of the salt, dissolved in a few drops of nitric acid, be evaporated to dryness, and a few drops of ammonia water added to the residue, an orange color will be produced, which will turn reddish-purple, and finally brown, on the addition of a small amount of alcoholic potassium hydroxide T.S. The addition of sulphuric acid to a crystal of Strychnine Nitrate on a white porcelain surface should not produce more than a faintly yellow color (limit of *brucine*).¹ *U. S.*

Uses.—Strychnine nitrate is employed for the same purposes as strychnine sulphate. (See *Strychnine Sulphas*.)

Dose, one-sixtieth to one-thirtieth of a grain (0.0011 to 0.002 Gm.).

STRYCHNINÆ SULPHAS. U. S.

STRYCHNINE SULPHATE

(strĭĭk-nĭ-næ sŭl'phās)

"The sulphate $[SO_2(OH)_2 \cdot (C_{21}H_{22}N_2O_2)_2 + 5H_2O]$ of the alkaloid strychnine. It should be kept in well-stoppered vials." *U. S.*

Strychnine Sulphas, *Pharm.* 1870; *Strychninum Sulphuricum*; *Sulfate de Strychnine*, *Fr. Cod.*; *Schwefel-saures Strychnin*, *Strychninsulfat*, *G.*; *Sulfato de estricina*, *Sp.*

Preparation.—A process for this salt is no longer official. That of the *U. S. P.* 1870 will be found in the foot-note.¹ Two forms of strychnine sulphate are known, the acid sulphate, or commercial sulphate, and the official or neutral sulphate. Commercial strychnine sulphate, $C_{21}H_{22}N_2O_2 \cdot H_2SO_4 + 2H_2O$, crystallizes in needles. The water is expelled at 150° C. (302° F.). To prepare the neutral sulphate $(C_{21}H_{22}N_2O_2)_2 \cdot H_2SO_4$, a solution of the acid sulphate is divided into two equal portions: one of these portions is precipitated by ammonia, and the precipitate is added to the other part of the solution and the mixture boiled. On cooling, the liquid deposits the neutral salt in transparent prisms containing 5 molecules of H_2O . The crystals melt and become anhydrous at 200° C. (392° F.). By the spontaneous evaporation of an aqueous solution of the salt, transparent pyramids belonging to the quadratic system are obtained. According to Rammelsburg, these crystals contain 6 molecules of H_2O . (*Ber. d. Chem. Ges.*, 1881, p. 1231; *N. R.*, Jan. 1882.)

Properties.—This salt is in "colorless, or

white prismatic crystals, or a white, crystalline powder; odorless, and having an intensely bitter taste, perceptible even in solutions of 1 in 700, 000. *Strychnine Sulphate should be tasted with extreme caution.* Efflorescent in dry air. Soluble in 31 parts of water, 65 parts of alcohol, and in 325 parts of chloroform at 25° C. (77° F.); soluble in 6 parts of water at 80° C. (176° F.), and in 20 parts of alcohol at 60° C. (140° F.); insoluble in ether. When heated at 100° C. (212° F.), the salt loses its water of crystallization (10.59 percent.), and when anhydrous melts at 200° C. (392° F.). Upon ignition, it is consumed, leaving no residue. Barium chloride T.S. produces in a solution of the salt a white precipitate, which is insoluble in hydrochloric acid. Sulphuric acid should produce no color with strychnine sulphate, but on adding a fragment of potassium dichromate, a blue color should be formed, changing to deep violet, then to purplish-red, cherry-red, and finally to orange or yellow. Sulphuric acid containing 1 percent. of ammonium vanadate produces a deep violet-blue color, changing to deep purple, and finally to cherry-red. Sulphuric acid containing a trace of potassium iodate produces a violet color, changing to reddish-purple. If 0.1 Gm. of the salt be dissolved in a few drops of nitric acid, evaporated to dryness, and a few drops of ammonia water added to the yellow residue, an orange color will be produced, which will turn momentarily reddish-purple, and finally brown, on the addition of a small amount of alcoholic potassium hydroxide T.S. Nitric acid, when added to a crystal of Strychnine Sulphate on a white porcelain surface, should not produce more than a faintly yellow color (limit of *brucine*).¹ *U. S.* The chief advantage of this preparation over strychnine is its much greater solubility in water, by which it is better adapted to external use, as for application to blistered surfaces, or for hypodermic injection, or as an ingredient in collyria. Owing to the presence of sulphuric acid and water of crystallization in this salt, it contains but about 75 per cent. of strychnine, and the proportionate dose would be therefore somewhat greater than that of the alkaloid.¹ (See *Strychnine*.)

¹ *Strychnine Arsenite* having been proposed as a remedy by Grimelli of Modena, Chiappero of Turin, undertook to prepare the salt. For this purpose he dissolved arsenic trioxide in water acidulated with hydrochloric acid, and neutralized the arsenic trioxide with strychnine. But, according to M. T. Ceresoli of Paris, the result was a mixture of strychnine arsenite and hydrochloride. The latter chemist prepares a pure strychnine arsenite in the following manner: He takes 3.12 grammes of potassium hydroxide, 3.30 of arsenic trioxide, and 40.00 of distilled water. Having dissolved the potassium hydroxide in the water, boiling hot, he adds the arsenic trioxide, which is completely dissolved. He then dilutes 2.65 grammes of monohydrated sulphuric acid with 20 grammes of distilled water, and, having heated the mixture to ebullition, adds 12 grammes of pure crystallized strychnine, which is entirely dissolved. The two solutions being kept at about the temperature of 100° F., he pours the arsenical solution into that of strychnine. A grumous mass is produced, much of which, however, is dissolved by heat. The liquid being filtered boiling hot from the undissolved mass,

¹ *Strychnine Sulphas*.—"Take of Strychnia a troy-ounce; Diluted Sulphuric Acid nine fluidrachms, or a sufficient quantity; Distilled Water a pint. Mix the Strychnia with the Distilled Water, heat the mixture gently, and gradually add Diluted Sulphuric Acid until the alkaloid is neutralized and dissolved. Filter the solution, and evaporate with a moderate heat, so that crystals may form on cooling. Lastly, having drained the crystals, dry them rapidly on bibulous paper, and keep them in a well-stopped bottle." *U. S.* 1870.

Dose, one-fortieth to one-twentieth of a grain (0.0016 to 0.003 Gm.).

STYRAX. U. S. (Br.)

STORAX
(stý'răx)

"A balsam obtained from the wood and inner bark of *Liquidambar orientalis* Miller (Fam. Hamamelidaceæ)." U. S. "A balsam obtained from the trunk of *Liquidambar orientalis*, Miller, and purified by solution in ethylic alcohol, filtration, and evaporation of the solvent." Br.

Styrax Præparatus, Br.; Prepared Storax; Styrax Liquidus, Balsamum Storacis, Balsamum Styracis, Balsamum Styrax Liquidus; Liquid Storax; Styrax liquide, Fr. Cod.; Styrax, P. G.; Storax, Flüssiger Storax, G.; Storace liquido, It.; Estoraque liquido, Sp.

All species of the genus *Liquidambar* as well as those of a related genus, *Altingia*, yield storax. The product most valued, however, is that obtained from *L. orientalis*, Miller.

Liquidambar orientalis, Miller, Gard. Dict. (1768) 8th ed. No. 2; B. & T. 107.—The oriental sweet-gum is a tree from twenty to forty feet high. The palmate leaves have each of their divisions obscurely three-lobed, and are serrate, perfectly smooth, bright green and shining on the upper and pale on the under surface. The tree is a native of Asia Minor, in the southwestern parts of which it forms large forests. It yields the so-called *liquid storax*.

According to the researches of Moeller, storax is a pathological rather than a physiological product; when the young wood is injured secretion reservoirs are formed in which the storax is produced. (O. Z., 1.) The more recent accounts of the method of collecting the drug indicate that the outer bark is first heavily bruised, so as to injure the inner bark, and after a time the outer bark having been removed the inner bark is scraped off. According to Maltass, this inner bark is first pressed cold

in horse-hair bags, after which hot water is thrown over the bags and they are again pressed. Lieutenant Campbell states that the inner bark is first boiled with water, and, a portion of the balsam which rises having been skimmed off, is then pressed so as to extract the remainder. The residuary bark, after expression, is dried in the sun, and employed in various parts of Turkey for fumigation. It is the drug known in commerce as *Storax bark* or *Cortex Thymiamatis*. (Hanbury, P. J., xvi. 463.) The balsam is sent in casks to Constantinople, Smyrna, and other ports of the Levant.

Several kinds of storax have been described. The purest was the *storax in grains*, which was in whitish, yellowish-white, or reddish-yellow tears, about the size of a pea, opaque, soft, adhesive, and capable of uniting so as to form a mass. Another variety, formerly called *styrax calamita*, from the circumstance, it is supposed, that it was brought wrapped in the leaves of a kind of reed, consisted of dry and brittle masses, formed of yellowish agglutinated tears, in the interstices of which was a brown or reddish matter. The French call it *storax amygdaloïde*. This and the preceding variety had a pleasant odor like that of vanilla. Neither of them, however, is now found in the markets. It is probable that one or both of these varieties may have been the product of *Styrax officinale*. A third variety, which is sometimes sold as the *styrax calamita*, is in brown or reddish-brown masses of various shapes, light, friable, yet possessing a certain degree of tenacity, and softening under the teeth. Upon exposure, it becomes covered upon the surface with a white efflorescence of styracin. It evidently consists of sawdust, united with a portion of the balsam. As found in commerce, it is usually in the state of a coarse, soft, dark-colored powder, mingled with occasional light friable lumps of various sizes, and containing very little of the balsam. When good, it should yield, upon pressure between hot plates, a brown resinous fluid having the odor of storax. Hanbury states that some of this variety is prepared at Trieste, Venice, and Marseilles, by mixing the residue of the liquidambar bark remaining after expression, and reduced to coarse powder, with genuine liquid storax. (P. J., April, 1863.)¹ A fourth

which consists almost exclusively of potassium sulphate, the filtered liquid is evaporated nearly to dryness, and the residue dissolved in absolute alcohol, by which the potassium sulphate is all left behind. The undissolved mass, after the first filtration, is repeatedly washed with alcohol; and the alcoholic solutions are mixed, concentrated, and set aside to crystallize. At the end of two days the arsenite separates in the form of cubic crystals.

Strychnine arsenite is in white cubic crystals, containing water, which they lose in contact with the air, becoming almost efflorescent. They are completely decomposed by heat, with an empyreumatic odor, and leave nothing but a black and porous charcoal. Towards the end of the vaporization, dense white vapors rise with the alliaceous odor of arsenic. The taste is bitter and metallic. Strychnine arsenite is soluble in 35 parts of cold and 10 of boiling water; is soluble also in alcohol, and less so in ether. Its formula is $(C_{12}H_{22}N_2O_8)HAsO_4$. Though scarcely yet employed, at least to any considerable extent, as a medicine, it would seem, from its constituents, to be likely to fulfil important indications, and has the advantage of a uniform composition. Consisting of two ingredients, each of which is perhaps scarcely inferior, as a remedy in intermittent fever, to any other except cinchona and its derivatives, it probably possesses strong antiperiodic powers, and might very properly be the subject of trial in any intermittent disease which proves rebellious to quinine,—the prescriber, however, being always on his guard against its poisonous action. Its commencing dose should not be larger than the smallest dose of strychnine. (J. P. O., 4e sér., 1. 343).

¹ False Storax, *Liquidambar styraciflua*, or Sweet Gum of our Southern States.—Its geographical range reaches into Mexico, and it yields a storax-like product in an abundance proportionate to the heat of the climate. A specimen from Guatemala is described by Flickiger and Hanbury as a yellow, opaque resin, of honey-like consistence, becoming transparent, amber-colored, and brittle by exposure to the air, and having a rather terebinthinous balsamic odor and but little taste. Sometimes it occurs as a thick golden-brown fluid. It contains cinnamic acid and styracin. (A. J. P., 1874, p. 161.) It is soluble in alcohol, and has been gathered to a considerable extent in the United States for the preparation of chewing gum. The resins of *Liquidambar formosana* and *L. altigiana* are known in Eastern commerce. *Malay storax* is an aromatic resinous product obtained from the *Altingia excelsa*, Noronha, *L. altigiana*, Bl. It is sometimes called *rasamala resin* and contains tannic acid besides a very minute amount of cinnamic and benzoic acids.

variety, which, under the name of *liquid storax*, is the one commonly used, is a semi-fluid, adhesive substance, brown or almost black upon the surface exposed to the air, but of a slightly greenish-gray color within, and of an odor somewhat like that of balsam of Peru, though less agreeable. It is kept in jars.

Properties.—The storax used by pharmacists should correspond to the following official directions and tests. "A semi-liquid, grayish, sticky, opaque mass, depositing, on standing, a heavy, dark brown stratum; transparent in thin layers, and having an agreeable odor and a balsamic taste. Insoluble in water, but completely soluble (with the exception of accidental impurities) in an equal weight of warm alcohol. If the alcoholic solution, which has an acid reaction, be cooled, filtered, and evaporated, it should leave not less than 70 percent. of the original weight of the balsam, in the form of a brown, semi-liquid residue almost completely soluble in ether and in carbon disulphide, but insoluble in petroleum benzin. When heated on a water-bath, Storax becomes more fluid, and if it be then agitated with warm petroleum benzin, the supernatant liquid, on being decanted and allowed to cool, will be colorless, and will deposit white crystals of cinnamic acid and cinnamic esters." *U. S.* "Heated in a test-tube placed in boiling water, it becomes more liquid, but gives off no moisture; boiled with solution of potassium bichromate and sulphuric acid, it evolves an odor resembling that of essential oil of bitter almonds." *Br.*

As found in commerce, storax is usually so much adulterated as to require purification before it can be used, and in both Pharmacopœias processes were formerly given. Whenever not originally pure enough for use, it should be dissolved in alcohol, the solution strained, and the alcohol distilled off to a certain extent, and then completely evaporated at a gentle heat. Among the substances used in the adulteration of storax is turpentine. To detect it Hager employed the following method. He liquefied the resin, in a tube, by means of a water bath, added half its volume of absolute alcohol, and hastened the solution by agitation; he then treated it with several volumes of benzin. This operation was repeated twice. The liquors obtained were then evaporated, in a tared vessel, and there was secured, for pure storax, a colorless residue (45 to 55 per cent.), with a light-blue opalescence; for that mixed with turpentine, a residue more considerable, yellowish, and having the terebinthinate odor. (*J. P. C.*, Fév. 1876, p. 161.)

Storax melts with a moderate heat, and, when the temperature is raised, takes fire and burns with a white flame, leaving a light, spongy, carbonaceous residue. It imparts its odor to water, which it renders yellow and milky. Its active constituents are dissolved by alcohol and ether. Neumann obtained from 480 grains of storax 120 of aqueous extract, and from an equal quantity 360 grains of alco-

holic extract. Containing volatile oil and resin, and yielding benzoic or cinnamic acid by distillation, it is entitled to rank as a balsam.

The most abundant constituent of storax is probably *storesin*, $C_{15}H_{11}O_2(OH)_3$, discovered in 1877 by W. von Miller. This is present both free and in the form of a cinnamic ester. Storesin is an amorphous substance, melting at $168^\circ C.$ ($334.4^\circ F.$), readily soluble in petroleum benzin. Cinnamic esters of phenylpropyl, cinnamic ester of ethyl, cinnamic ester of benzyl, and especially cinnamate of cinnamyl, $C_6H_7O_2.C_6H_5$, the so-called *styracin* of Bonastre, have also been observed. This last compound can be removed by ether, benzene, or alcohol after the separation from the resin of the cinnamic acid; it is insoluble in water, and volatile only in superheated steam. It crystallizes in tufts of long rectangular prisms, which melt at $38^\circ C.$ ($100.4^\circ F.$), but frequently do not solidify readily. By concentrated solution of potassium hydroxide, it is resolved into a cinnamate and cinnamic alcohol (*styrone*), $C_{15}H_{11}O$, which latter is not present in liquid storax. The yield of cinnamic acid varies from 6 to 12 per cent., or even, according to Löwe, as much as 23 per cent. of crystallized cinnamic acid can be obtained. The acid dissolves abundantly in ether, alcohol, or hot water, slightly in cold water; it is inodorous, but has an acrid taste. It fuses at $133^\circ C.$ ($276.4^\circ F.$), and boils at $290^\circ C.$ ($554^\circ F.$). Another minor constituent of storax is a fragrant substance melting at $65^\circ C.$, and possessing the odor of vanillin, which Rump (*Ber. d. Chem. Ges.*, 1878, 1034) identified. Miller also shows that water removes from the drug a little free benzoic acid. There is further found in liquid storax a hydrocarbon, C_8H_8 , first prepared by Simon in 1839, which exists in the resin as a liquid, and also in a polymeric form as a solid. The former, called *styrol* or *cinnamene*, has a sp. gr. of 0.924, and a boiling point of $146^\circ C.$ ($294.8^\circ F.$). It is a colorless, mobile liquid, possessing the odor and burning taste of liquid storax. It has since been formed synthetically, and has been recognized as *phenylethylene*, $C_6H_5.CH=CH_2$. When heated for a considerable time to $100^\circ C.$ ($212^\circ F.$), or for a shorter period to $200^\circ C.$ ($392^\circ F.$), it is converted without change of composition into the colorless, transparent solid *metastyrol*, which, unlike styrol, is not soluble in alcohol or in ether. Lastly, there has been found in liquid storax, by J. H. van t'Hoff (1876), about 0.4 per cent. of a pleasant-smelling laevo-rotatory oil of the formula $C_{10}H_{16}O$. (*Pharmacographia*, 2d ed., 274 and 275.) Tschirch and L. v. Itallie (*A. Pharm.*, Sept. 1901, 506) state that styrax contains free cinnamic acid, vanillin, styrol, styracin, cinnamic acid-ethyl ester, cinnamic acid-phenylpropyl ester and storesinol partly free and partly as cinnamic acid ester.

Uses.—Styrax is a stimulating expectorant and very feeble germicide, which was at one

time used in various *pulmonic catarrhs*, also in *gonorrhœa* and *leucorrhœa*, but at present is very seldom used except as a constituent of the compound tincture of benzoin. Externally, mixed with two or three parts of olive oil, liquid storax was found by H. Schultze of Magdeburg, to be very effective as a local remedy in scabies.

Dose, ten to twenty grains (0.65 to 1.3 Gm.).

Off. Prep.—Tinctura Benzoini Composita, *U. S.*, *Br.*

SUCCI.

JUICES

(sūc'cī)

Sucs végétaux, *Fr.*; Pflanzensäfte, *G.*

Though introduced to professional notice by Squire in the year 1835, and subsequently used by many practitioners, the Juices were recognized but once by the *U. S. Pharmacopœia* (1870). They consist of the expressed juices of fresh plants, preserved by the addition of one-third of their bulk of alcohol. Considering the great inequality in strength, and of course the uncertainty in operation, of fresh juices themselves, varying according to the soil, climate, mode of cultivation, season, and the age of the plant, it may be questioned whether they merit the prominence which has been given them in the *British Pharmacopœia*.

SUCCUS BELLADONNÆ. Br.

JUICE OF BELLADONNA

(sūc'cus bēl-lā-dōn'næ)

Suc de Belladone, *Fr.*; Belladonnasaft, *G.*

"Bruise the fresh leaves and young branches of *Atropa Belladonna*, *Linn.*; press out the juice; to every three volumes of juice add one of Alcohol (90 per cent.); set aside for seven days; filter." *Br.*

Dose, five to fifteen minims (0.3 to 0.9 Cc.).

SUCCUS CONII. Br.

JUICE OF CONIUM

(sūc'cus cō-nī'i)

Juice of Hemlock; Suc de grande Ciguë, *Fr.*; Schierlingsaft, *G.*

"Bruise the fresh leaves and young branches of *Conium maculatum*, *Linn.*; press out the juice; to every three volumes of juice add one of Alcohol (90 per cent.); set aside for seven days; filter." *Br.*

The albumen is probably coagulated under the influence of the alcohol; and hence the propriety of directing filtration.

The experiments of John Harley (*A. J. P.*, 1867, 363) seemed to indicate that the juice is the best preparation of conium. He found that one fluidounce of it contained 0.42 grain of the alkaloid, and that five and a half fluidrachms of it produced very severe and char-

acteristic symptoms. Subsequent experience has shown, however, that Succus Conii, at least as it reaches Philadelphia, is even in the best brands a very uncertain preparation, distinctly inferior in every way to the *U. S. fluidextract* made from the green fruit. (See *Y. B. P.*, 1896, 292.)

Dose, one fluidrachm (3.75 Cc.), which may be increased until some effects are produced.

Off. Prep.—Unguentum Conii, *Br.*

SUCCUS HYOSCYAMI. Br.

JUICE OF HYOSCYAMUS

(sūc'cus hÿ-ōs-cÿ'a-mī)

Suc de Jusquame, *Fr.*; Bilsenkrautsaft, *G.*

"Bruise the fresh leaves, flowering tops, and young branches of *Hyoscyamus niger*, *Linn.*; press out the juice; to every three volumes of juice add one of Alcohol (90 per cent.); set aside for seven days; filter." *Br.*

Dose, one-half to one fluidrachm (1.8 to 3.75 Cc.).

SUCCUS SCOPARII. Br.

JUICE OF BROOM

(sūc'cus scō-pā'rī-i)

Suc de Genet à Balais, *Fr.*; Besenginstersaft, *G.*

"Bruise fresh Broom Tops; press out the juice; to every three volumes of juice add one of Alcohol (90 per cent.); set aside for seven days; filter." *Br.*

In large doses this juice is prone to disturb the stomach and bowels. It is more appropriately used as an adjuvant to other diuretics than alone.

Dose, as a diuretic, one to two fluidrachms (3.75 to 7.5 Cc.).

SUCCUS TARAXACI. Br.

JUICE OF TARAXACUM

(sūc'cus tā-rāx'a-cī)

Suc de Pissenlit, *Fr.*; Löwenzahnwurzel-saft, Löwenzahnsaft, *G.*

"Bruise fresh Taraxacum Root; press out the juice; to every three volumes of juice add one of Alcohol (90 per cent.); set aside for seven days; filter." *Br.*

Dose, two fluidrachms to half a fluidounce (7.5 to 15 Cc.).¹

¹ *Procter's Preserved Juice of Taraxacum.*—Of the fresh roots collected in September or October, twenty pounds avoirdupois are to be sliced transversely, reduced to a pulpy mass by grinding or confusion, then thoroughly incorporated with four pints of alcohol sp. gr. 0.835, and set aside in stoneware jars. After a week, or a longer time, the pulpy mass is to be subjected to strong pressure, and the liquor filtered and bottled for use. Even after six months the pulp thus treated preserves the sensible properties of the dandelion in a marked degree. Should the alcohol in the expressed liquor be objected to, it may be partially removed by evaporation by means of a water bath until the bulk of the juice has been diminished one-sixth; eight ounces of sugar are then added for every pint. (*A. J. P.*, xxv.)

SULPHONETHYLMETHANUM. U. S.

SULPHONETHYLMETHANE

(sũl-phôn-ê-thỹl-mêth-ă-nũm)

"Diethylsulphonemethylethylmethane [(CH₃) (C₂H₅)C(SO₂C₂H₅)₂], a product of the oxidation of the mercaptol obtained by the condensation of methylethylketone with ethylmercaptan. It should be preserved in well-stoppered vials." U. S.

Trional, Trionalum; Diethylsulphone-methylethylmethane; Trional, Fr. Cod.; Diethylsulfone-méthylethyl-méthane, Fr.; Methylsulfonyl, P. G.; Methylsulfonyl, Trional, G.; Trional, Sp.

Preparation.—Sulphonethylmethane is made by passing hydrochloric acid gas to saturation through a mixture of ethyl mercaptan and methyl ethylketone, then oxidizing the condensation product (methyl-ethyl-ketone mercaptol) by treating it with a weak solution of potassium permanganate; the compound is purified by repeated crystallization from its solutions in boiling water.

Sulphonethylmethane (or trional) and tetronal¹ are substances which are members of the group of disulphones to which sulphonal belongs and are respectively *diethylsulphon-methylethylmethane* and *diethylsulphon-diethyl-methane*. Their relationship to sulphonal (diethylsulphon-dimethyl-methane) will be readily seen by a comparison of formulas.

Sulphonal.

Trional.

Tetronal.

Properties.—It is officially described as in "colorless, lustrous, odorless, crystalline scales, which have a bitter taste in aqueous solution. Soluble in 195 parts of water at 25° C. (77° F.), more readily in boiling water, and readily soluble in alcohol and ether. When heated to 76° C. (168.8° F.), it melts, and at a red heat is consumed, evolving sulphur dioxide and leaving no weighable residue. Its aqueous solution is neutral to litmus paper. If 0.1 Gm. of Sulphonethylmethane be heated with 0.1 Gm. of powdered charcoal in a dry test-tube, the characteristic unpleasant odor of mercaptan will be developed. If 0.1 Gm. be gradually heated with dried sodium acetate, hydrogen sulphide will be evolved. One Gm. dissolved in 50 Cc. of boiling water should develop no odor. This so-

¹ Tetronal, (C₂H₅)₂C(SO₂C₂H₅)₂. *Diethyl sulphone diethyl methane* is made by the same process as that used for sulphonal or sulphonmethane (see page 1201) with the exception that diethylketone is used in place of acetone; the product (diethyl ketone mercaptol) is oxidized by treatment with potassium permanganate and the crystals purified. It occurs in colorless, crystalline scales, melting at 85° C. (185° F.); soluble in 450 parts of cold water and readily soluble in alcohol and ether.

Tetronal acts physiologically like trional but has failed to come into use as a hypnotic. Practically in pure insomnia not due to pain, trional is the most effective, least disturbing and most used of the hypnotics.

lution, when cooled and filtered, should show no turbidity on the addition of barium nitrate T.S. or silver nitrate T.S. (absence of *sulphates* and *chlorides*). One drop of potassium permanganate T.S. added to the aqueous solution of Sulphonethylmethane should not be immediately decolorized (absence of *readily oxidizable organic impurities*)." U. S.

Uses.—Sulphonethylmethane or trional is devoid of local properties, is absorbed rapidly and acts much more promptly than does sulphonal. Given to man in doses of from fifteen to twenty grains (1.0 to 1.3 Gm.), it usually causes in from fifteen minutes to an hour a quiet, apparently normal, sleep, without unpleasant after-effects.

There appears to be no recorded case of fatal acute poisoning by trional. Sixty grains (3.9 Gm.) are said to have produced hæmatoporphyria, but one hundred and twenty grains (7.7 Gm.) have been recovered from without very serious symptoms. Although trional is less prone than is sulphonal to cause chronic poisoning, a number of cases have occurred. The symptoms have been great lassitude, giddiness, headache, tinnitus aurium, gastro-intestinal pain, vomiting, obstinate constipation, pronounced tremors, ataxia, especially shown by an uncertain gait, general paresis, with loss of control over the sphincter; also lessened secretion of the urine, and hæmatoporphyria. Strangury has been noted, while even the therapeutic dose may cause excessive acidity of the urine. These symptoms differ from those produced by sulphonal chiefly in that the hæmatoporphyria is less pronounced, the premonitory symptoms are more marked, and the result much less frequently death.

In acute trional poisoning the stomach should be evacuated; very dilute solution of sodium carbonate should be given freely by the mouth and by hypodermoclysis; strychnine and cardiac stimulants used hypodermically *pro re nata*. In chronic poisoning the most important part of the treatment is the free administration in every possible way of a one per cent. solution of sodium carbonate.

Dose, ten to twenty grains (0.65 to 1.3 Gm.).

SULPHONMETHANUM. U. S., Br.

SULPHONMETHANE

(sũl-phôn-mêth-ă-nũm)

"Diethylsulphonedimethylmethane [(CH₃)₂C(SO₂C₂H₅)₂], the product of the oxidation of the mercaptol obtained by the condensation of acetone with ethylmercaptan. It should be preserved in well-stoppered vials." U. S. "Sulphonal, or dimethyl-methane-diethylsulphone, (CH₃)₂C(SO₂C₂H₅)₂, is a product of the oxidation of mercaptol, (CH₃)₂C(SC₂H₅)₂, obtained from acetone and mercaptan." Br.

Sulphonal, Br.; Diethylsulphon-dimethyl-methane; Acetone-diethylsulfone, Fr. Cod.; Sulfonylum, P. G.; Sulfonyl, G.; Sulfonyl, It.; Sulfonyl, Sp.

Preparation.—This compound belongs to the class of disulphones, to which belong also trisulphonal and tetrathional. (See page 1200.) It may be made by the following processes. When anhydrous mercaptan (ethyl sulphhydrate) and anhydrous acetone are mixed and a stream of dry hydrochloric acid gas passed through, the liquid gradually becomes turbid and separates into two layers, the upper being mercaptol (dithioethyl-dimethylmethane), the lower, diluted hydrochloric acid. The mercaptol is separated, washed, and then oxidized with potassium permanganate, the liberated oxygen converting the mercaptol into sulphonal. It may also be prepared by the action of ethyl chloride on sodium thiosulphate, the resulting sodium ethyl thiosulphate being converted into ethyl mercaptan and acid sodium sulphate by the action of water. This conversion is made to take place in the presence of alcohol, hydrochloric acid, and acetone, the ethyl mercaptan being condensed to mercaptol, which is oxidized by potassium permanganate, sulphonal being the result. It forms heavy colorless prismatic crystals, melting at 125.5° C., which are not very soluble in cold water, but more readily in boiling water, and in alcohol and alcoholic ether. A characteristic test is to fuse the sulphonal in a small dry test-tube, heat to about 280° C., and to the clear liquid add pyrogallie (or gallic) acid. The liquid becomes brown and gives off the characteristic odor of mercaptan or sulphur alcohol. Heating with potassium cyanide or even with powdered charcoal will effect the same decomposition.

Properties.—It is officially described as in "colorless, inodorous, and nearly tasteless prismatic crystals. Soluble in 360 parts of water, 47 parts of alcohol, 45 parts of ether, and in 16 parts of chloroform at 25° C. (77° F.); soluble in 15 parts of boiling water, and in 2 parts of boiling alcohol; soluble in benzene. When heated to 125.5° C. (258° F.) it melts, and at a red heat it is consumed, evolving vapors of sulphur dioxide and leaving no weighable residue. Its aqueous solution is neutral to litmus paper. If 0.1 Gm. of Sulphonmethane be heated with 0.1 Gm. of powdered charcoal in a dry test-tube, the characteristic unpleasant odor of mercaptan will be developed. If 0.1 Gm. be gradually heated with dry sodium acetate, hydrogen sulphide will be evolved. Its solution in boiling water should develop no odor. This solution, after cooling and filtering, should show no turbidity upon the addition of either barium nitrate T.S. or silver nitrate T.S. (absence of *sulphates* and *chlorides*). If 1 drop of potassium permanganate T.S. be added to an aqueous solution of Sulphonmethane, the liquid should not be immediately decolorized (absence of *readily oxidizable organic impurities*)."
U. S. The British Pharmacopœia gives the following description: "Colorless, inodorous, nearly tasteless prismatic crystals; without action on *litmus*; melting at 258° F. (125.5° C.). Soluble in 15 parts of boiling

water, in 450 parts of cold water, in 50 parts of cold alcohol (90 per cent.), very soluble in boiling alcohol (90 per cent.), soluble in ether. Heated to redness with free access of air, it burns, evolving sulphurous anhydride, and leaving no residue (absence of mineral impurity). If a mixture of Sulphonal with an equal weight of *potassium cyanide* be heated, the odor of mercaptan is evolved, and when to the solution of the product in water excess of *hydrochloric acid* and a few drops of *test-solution of ferric chloride* are added, a reddish color is developed. It evolves hydrogen sulphide when gradually warmed with dried *sodium acetate*. It should yield no characteristic reaction with the tests for chlorides or sulphates." Br.

Uses.—In the lower animals sulphonmethane produces sleep, which, if the dose has been sufficient, deepens into coma accompanied by paresis, tremors, and convulsions. Occasionally loss of power notably in the hind legs precedes the cerebral symptoms. The action of the drug upon the circulation seems to be very feeble although it has not been thoroughly made out. According to Schiek, the nerves and muscles are not altered, so that the symptoms must be centric in origin. Kast found that the blood is not changed, and, according to W. J. Smith, tissue-change is not influenced.

Kast believed that sulphonal is eliminated in the form of a highly soluble organic compound, probably a sulphonic acid. Jaffe and Jolles have, however, each obtained unaltered sulphonal from the urine; but it would appear probable that the greater part of the sulphonal splits up in the system so as to yield ethylsulphonic acid, which escapes in the urine (W. J. Smith).

When sulphonal is given to human beings in doses of from fifteen to thirty grains, sleep usually develops in from half an hour to an hour. It is usually quiet, and not followed by disagreeable after-effects, although sometimes mental confusion and lassitude remain. Over pain sulphonal exerts no influence. It was originally asserted by Kast that the drug would prove especially useful in *insomnia* from cardiac diseases, but further experience does not sustain this. Occasionally sulphonal produces nausea, headache, depression or other disagreeable after-effects, and in old people or those suffering from mental enfeeblement, mental confusion is likely to occur. Chronic poisoning has frequently been caused by the continuous use of sulphonal. The symptoms develop suddenly without distinct prodromes, and usually continue to the fatal issue (75 per cent. of cases). The most characteristic and often first manifestation is pink to dark red urine, which stains linen, etc., followed by constipation, vomiting, gastric tenderness, ataxia, anuria, paresis, loss of reflexes, albuminous, bloody or suppressed urine, collapse; after death a widespread fatty degeneration has been found. No effective treatment is known, but large amounts of alkaliized water (soda) should be given by

the mouth and by hypodermoclysis. Even after therapeutic doses of sulphonal a measles-like rash often appears.

Whenever sulphonal is given largely or for a length of time, the urine should be carefully watched, and any smoky or dark appearance of the excretion should be the signal for the immediate withdrawal of the drug. That enormous doses of sulphonal may be recovered from is shown by the case reported by Neisser, in which over three ounces are said to have been taken, six hours elapsing before any medical treatment was instituted. In the case reported by Knaggs, four hundred and fifty grains produced death after unconsciousness lasting for three days, with complete anuria.

Dose, from ten to forty grains (0.65 to 2.6 Gm.), which should always be given in fine powder, compressed pills frequently passing through the bowels unchanged.

SULPHUR LOTUM. U. S.

WASHED SULPHUR

(sūl'phūr lō'tūm)

S = 31.83

"Washed sulphur, when dried, should contain not less than 99.5 percent. of pure Sulphur." *U. S.*

Flores Sulphuris Loti; Soufre Sublimé Lavé, Fr. Cod.; Sulphur Depuratum, P. G.; Gereinigter Schwefel, Gereinigte Schwefelblumen, G.; Solfo sublimato e lavato, It.; Azufre lavado, Sp.

* "Sublimed Sulphur, one hundred grammes [or 3 ounces av., 231 grains]; Ammonia Water, ten cubic centimeters [or 162 minims]; Water, a sufficient quantity. Pass the Sublimed Sulphur through a No. 30 sieve, mix it thoroughly with one hundred cubic centimeters [or 3 fluid-ounces, 183 minims] of Water, add the Ammonia Water, and digest for three days, agitating occasionally. Then add one hundred cubic centimeters [or 3 fluidounces, 183 minims] of Water, transfer the mixture to a muslin strainer, and wash the Sulphur with Water until the washings cease to impart a blue color to red litmus paper. Then allow it to drain, press the residue strongly, dry it rapidly at a moderate heat, pass it through a No. 30 sieve, and keep it in well-stoppered bottles." *U. S.*

Sublimed sulphur is frequently contaminated with small quantities of sulphuric acid and other impurities, and the object of the ammonia in the above process is to neutralize the acid, the salt being subsequently washed out and to remove any arsenical contamination. (See *Sulphur Sublimatum*.)

Properties.—It is officially described as "a fine yellow powder, without odor or taste. Insoluble in water; readily soluble in carbon disulphide; slightly soluble in absolute alcohol; more readily soluble in petroleum benzin, benzene, oil of turpentine, and many other oils; also in ether, chloroform, and in boiling aqueous solutions of alkali hydroxides. At about 115°

C. (239° F.) it fuses to a yellow, mobile fluid, which upon further heating becomes dark and viscid, until a temperature above 300° C. (572° F.) is reached, when it becomes a thin liquid boiling at 448° C. (838.4° F.). If air be admitted, it burns to sulphur dioxide, which is identified by its characteristic odor, and by its blackening a strip of paper moistened with mercurous nitrate T.S. held in the gas. The amount of residue left after volatilizing or igniting a weighed portion of dried Washed Sulphur should not exceed 0.2 percent. If 0.5 Gm. of Washed Sulphur be boiled with 10 Ce. of sodium hydroxide T.S., it should be dissolved, leaving no appreciable residue (absence of earthy and metallic impurities). If 0.5 Gm. of Washed Sulphur be digested for several hours with 10 Ce. of ammonia water, the liquid filtered, and the clear filtrate evaporated to dryness on a water-bath, then, after adding 1 Ce. of nitric acid and again evaporating, the solution obtained by dissolving the residue in 10 Ce. of hydrochloric acid (8 percent.) should not respond to the Modified Gutzzeit's Test for arsenic (see PART III, Test No. 17). If 5 Ce. of water be agitated with 2 Gm. of Washed Sulphur, the liquid should not change the color of blue or red litmus paper (absence of acid and of ammonia)." *U. S.*

Dose, one to three drachms (3.9 to 11.6 Gm.).

Off. Prep.—*Pulvis Glycyrrhizæ Compositus, U. S.; Sulphuris Iodidum, U. S.; Unguentum Sulphuris, U. S.*

SULPHUR PRÆCIPITATUM. U. S., Br.

PRECIPITATED SULPHUR [Milk of Sulphur, Br.]

(sūl'phūr præ-cīp-i-tā'tūm)

S = 31.83

"Precipitated Sulphur, when dried, should contain not less than 99.5 percent. of pure Sulphur." *U. S.* "Sulphur precipitated by hydrochloric acid from a solution of calcium sulphides and thiosulphate, which has been made by boiling together sulphur and lime in water." *Br.*

Lac Sulphuris; Milk of Sulphur; Magisterium Sulphuris; Soufre précipité, Fr. Cod.; Lait de Soufre, Fr.; Sulfur præcipitatum, P. G.; Schwefelmilch, G.; Solfo precipitato, It.

* "Sublimed Sulphur, one hundred grammes [or 3 ounces av., 231 grains]; Lime, fifty grammes [or 1 ounce av., 334 grains]; Hydrochloric Acid, Water, each, a sufficient quantity. Slake the Lime, and mix it uniformly with five hundred cubic centimeters [or 16 fluidounces, 435 minims] of Water. Add the Sublimed Sulphur, previously sifted, and, after thorough mixing, add one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Water, and boil the mixture in a porcelain or glass vessel during one hour, stirring or agitating very frequently, and replacing the Water lost by evaporation. Then cover the vessel, and permit the contents to cool and become clear by subsidence.

Carefully draw off the clear solution, and filter the remainder. To the united liquids add gradually, and with constant stirring, Hydrochloric Acid previously diluted with an equal volume of Water, until the liquid is nearly neutralized, still retaining, however, an alkaline reaction and a yellow color. Collect the precipitate on a strainer, and wash it, until the washings are tasteless and cease to give a precipitate upon the addition of ammonium oxalate test solution. Then dry the product rapidly, at a moderate heat, and keep it in well-stoppered bottles." *U. S.*

The process for precipitated sulphur was not changed in the last revision. The Br. Pharm. in its official definition outlines the method used in the U. S. preparation.

In the U. S. process three molecules of calcium oxide react with six atoms of sulphur to form two molecules of calcium disulphide and one of calcium thiosulphate (hyposulphite);

On the addition of the hydrochloric acid, six atoms of sulphur are precipitated (four from the two molecules of calcium disulphide and two from the one molecule of calcium thiosulphate), and the calcium and oxygen unite with the hydrochloric acid, so as to form calcium chloride and water, according to the reaction:

This rationale is not exactly applicable to the British process of 1885, in which the proportion of the sulphur to the lime employed was greater than in that of the U. S. Pharm., and on account of this greater excess of sulphur the reaction takes place as follows:

a calcium pentasulphide being formed. Hydrochloric acid is the most eligible precipitant for the sulphur, as it gives rise to calcium chloride, which is a very soluble salt and is easily washed away. Sulphuric acid is wholly inadmissible, as it generates calcium sulphate, which, from its sparing solubility, becomes necessarily intermingled with the precipitated sulphur. According to Schweitzer, the best material from which to precipitate the sulphur is potassium sulphide, formed by boiling sulphur with potassium hydroxide. Otto of Brunswick, finds that potassium sulphide is likely to contain copper sulphide, and therefore he prefers calcium sulphide.

Properties.—Precipitated sulphur is in friable lumps, of a white color, with a pale yellowish-green tint, and consisting of finely divided particles slightly cohering, or, as officially described, is "a fine, amorphous powder, of a pale yellow color, without odor or taste. Insoluble in water; very slightly soluble in absolute alcohol; readily soluble in carbon disulphide, petroleum benzin, benzene, oil of turpentine, and many other oils; also in ether, chloroform, and in boiling aqueous solutions of alkali hydroxides. At 115° C. (239° F.) Precipitated Sulphur melts, and at a higher tem-

perature it volatilizes, or, if air be admitted, burns to sulphur dioxide. If 1 Gm. of Precipitated Sulphur be ignited, it should not leave a weighable residue. If 1 Gm. of Precipitated Sulphur be digested for several hours with 10 Cc. of ammonia water and the liquid filtered, one-half of the clear filtrate should not leave a residue on evaporation; if the remainder be evaporated to dryness on a water-bath, then, after adding 1 Cc. of nitric acid and again evaporating, the solution obtained by dissolving the residue in 10 Cc. of hydrochloric acid (8 percent.) should not respond to the Modified Gutzeit's Test for arsenic (see PART III, Test No. 17). If 5 Cc. of water be agitated with 2 Gm. of Precipitated Sulphur, the liquid should not change the color of blue or red litmus paper (absence of acid and alkali)." *U. S.* For a paper on Selenium in Sulphur by T. D. Reed, see *Proc. A. Ph. A.*, 1897, 251. "A grayish-yellow soft powder, free from grittiness and from the smell of hydrogen sulphide. Under the microscope it is seen to consist of opaque globules, without any admixture of crystalline matter. It responds to the chemical tests mentioned under 'Sulphur Sublimatum.'" *Br.* The German test, that 1 Gm. of precipitated sulphur should dissolve in 5 Gm. of carbon disulphide, is trustworthy, according to Fittinger. Precipitated sulphur is entirely dissipated by heat; water boiled with it should not redden litmus. When recently prepared, it is devoid of taste, but possesses a peculiar odor. When long exposed, in a moist state, to the air, it becomes strongly contaminated with sulphuric acid. From its color it was formerly called *lac sulphuris*, or *milk of sulphur*. It is insoluble in water, but dissolves in a boiling solution of potassium hydroxide, and in oil of turpentine by the aid of heat. When of a brilliant white color, the presence of calcium sulphate may be suspected, in which case the preparation will not be wholly volatilized by heat. If pure, it communicates a harsh feel when rubbed between the fingers, owing to the friction of the particles. Precipitated sulphur differs from sublimed sulphur in being in a state of more minute division, and in presenting, after fusion, a softer and less brittle mass. Its peculiarities are supposed to depend upon the presence of water, which, however, is found in too small a quantity to constitute a regular hydrate. According to Rose, its white color is occasioned by the presence of a small proportion of hydrogen sulphide. Soubeiran states that it always contains some hydrogen sulphide, causing it to differ as a therapeutic agent from sublimed sulphur.

Uses.—Precipitated sulphur possesses medicinal properties similar to those of sublimed sulphur. Its state of extreme division renders it more readily suspended in liquids. It is sometimes selected for forming sulphur ointments; these are lighter in color and smoother than those made with sublimed sulphur.

Dose, one to three drachms (3.9 to 11.6 Gm.).

Natural States.—Sulphur is very generally disseminated throughout the mineral kingdom, and is almost always present, in minute quantity, in animal and vegetable matter. Among vegetables, it is particularly abundant in mustard and other cruciform plants. It occurs in the earth either native or in combination. When native it is found in masses, translucent or opaque, or in the powdery form mixed with various earthy impurities. In combination it is usually united with certain metals, as iron, lead, mercury, antimony, copper, and zinc, forming compounds called sulphides. *Native sulphur* is most abundant in volcanic countries, and is hence called *volcanic sulphur*. The most productive mines of sulphur are found in Sicily (400 distinct sulphur workings existing there, with a present annual production of 538,354 tons) and in the former Pontifical States. In 1869 or 1870 sulphur in large masses was discovered in the volcanic island of Saba, one of the Dutch West Indies, about 110 miles south of St. Thomas. Sulphur exists as a mineral in widely separated localities and in enormous quantities in the Western United States. A large mine of native sulphur has been opened in California, about twenty miles from Santa Barbara, and seven from the sea coast. In 1872 a great hill of almost pure sulphur was found about 900 miles west of Omaha and 30 miles south of the Union Pacific Railroad. Two hundred miles south of Salt Lake City there is a deposit of sulphur two thousand feet square and of an unknown thickness, shafts having been sunk sixty feet without reaching the bottom. This sulphur is said to be free from arsenic and antimony and is a surface deposit. Much sulphur has been found in Mount Humboldt, Nevada, and Sulphur Mountain, as it is called, in the Yellowstone National Park, is largely composed of the mineral. The only localities in the United States in which sulphur

is actively mined, however, are the Cove Creek Mine, Utah, and in Calcasieu Parish, La., where the Union Sulphur Company is now operating on an extensive scale, and a sulphur deposit underlying a quicksand is being mined by the Frasch process. A double-walled iron pipe is driven through the quicksand into the sulphur bed, and steam having been sent down between the walls of the pipe, the melted sulphur is raised in the inner pipe. An annual production of 300,000 tons can readily be obtained from this locality. Sulphur exists in large quantities in various localities in Japan. It is estimated that at Atosanobori there are five million tons of superior ore. The importations of sulphur from Sicily amounted in 1903 to 191,033 tons, but in 1905 dropped to 84,579 tons; the domestic production in 1903 was 35,098 tons, but in 1905 it increased to 232,000 tons. It is probable that in a year or two the Louisiana production will bring about the cessation of all importation from Sicily.

An estimate of the amount of sulphur consumed in the United States during 1902 to 1904 is presented in the table below.

Extraction.—Sulphur is obtained either from sulphur earths or from the native iron and copper sulphides, called iron and copper pyrites. The sulphur earths are placed in earthen pots set in oblong furnaces of brick work. From the upper and lateral part of each pot a tube proceeds obliquely downwards, which communicates with the upper part of a similar pot, situated outside the furnace, and perforated near its bottom, to allow the melted sulphur to flow into a vessel containing water, conveniently placed to receive it. Fire being applied, the sulphur rises in vapor, leaving the impurities behind, and, being condensed again, flows from the perforated pot into a vessel containing the water. Sulphur as thus obtained is called *crude sulphur*, and contains about one-twelfth of its weight of earthy matter. For purification it is generally melted in a cast iron vessel. When the fusion is complete, the impurities subside, and the purer sulphur is dipped out and poured into cylindrical wooden moulds, which give it the form of solid cylinders about an inch in diameter, called in commerce *roll sulphur* or *cane brimstone*. The dregs of this process, ground to powder, constitute a very impure kind of sulphur, of a gray color, called in commerce *sulphur vivum* or *horse brimstone*. The above process purifies the sulphur but imperfectly. At the same time it causes a considerable loss, as the dregs just mentioned contain a large proportion of sulphur. A more eligible

mode of purification consists in distilling the crude sulphur from a large cast iron still set in brickwork over a furnace, and furnished with an iron head. The head has two lateral communications, one with a chamber of brick work, the other with an iron receiver immersed in water, which is constantly renewed to cool it sufficiently to cause the sulphur to condense in the liquid form. When the tube between the still and the receiver is shut, and that communicating with the chamber is open, the sulphur condenses on its walls in the form of an impalpable powder, and constitutes *sublimed sulphur*, or *flowers of sulphur*. If, on the other hand, the communication with the chamber be closed, and that with the receiver open, the sulphur will condense in the latter in the fused state, and, when cast in cylindrical moulds, forms the *roll sulphur* of commerce.

In the island of Anglesea, and at Swansea, Wales, large quantities of sulphur are obtained from imported Spanish copper pyrites in the process for extracting the metal. The furnaces in which the ore is roasted are connected with chambers in which the volatilized sulphur is condensed.

A process for separating pure sulphur from the residue of the manufacture of soda (calcium sulphide), proposed by Max Schaffner, has been used in most of the soda factories of Germany, and has been introduced, to a greater or less extent, in England, France, and Belgium. (See details, *A. J. P.*, 1869, p. 545.) We shall confine ourselves to an outline. The process is divided into three parts: *first*, the preparation of the *soda solution* by heaping up the soda residue in the air, whereby oxidation takes place, and polysulphides and thiosulphates are formed, which are extracted by lixiviation; *secondly*, the solution thus obtained is decomposed in close stone or iron vessels, by hydrochloric acid, which decomposes the polysulphides and thiosulphates, with precipitation of sulphur; and, *thirdly*, the sulphur is obtained pure by fusing it under water, with steam and a pressure of $1\frac{1}{2}$ atmospheres. Calcium chloride remains in solution, gypsum is suspended, and the addition of a little milk of lime neutralizes any free acid present, and with the sulphur forms calcium sulphide, which dissolves whatever arsenic sulphide may be present, leaving the sulphur free from impurities. This collects in the bottom of the kettle, and is drawn off into moulds. From 60 to 65 per cent. of pure sulphur is thus obtained from the soda residue. A. M. Chance (*J. Soc. Chem. Ind.*, 1888, p. 162) has described a process which, after several years of experiment has been perfected, and seems likely to solve definitely the problem of sulphur recovery, if, as stated, 95 per cent. of the sulphur can be either recovered as brimstone or burned in sulphur furnaces for the manufacture of sulphuric acid. Chance passes limekiln gases (carbon dioxide and nitrogen) into the vats of alkali waste, liberating thereby the sulphur as hydro-

gen sulphide. This mixed with nitrogen goes into another vessel of alkali waste, when H_2S and CaS unite to form $\text{Ca}(\text{HS})_2$, a calcium sulphhydrate, while the nitrogen is allowed to escape. The $\text{Ca}(\text{HS})_2$ is now decomposed by a fresh quantity of CO_2 , and thus liberates a double quantity of hydrogen sulphide. This is so pure that when mixed with the requisite quantity of air and passed over anhydrous ferric oxide at a dull red heat the hydrogen is burned, liberating the sulphur, according to the reaction:

The sulphur can be obtained either in the sublimed or in the fused form, according to the temperature of the chamber. The present annual production by the Chance process in England amounts to 20,000 tons.

Crude sulphur comes to this country principally from Messina, in Sicily, and the ports of Italy. Roll sulphur and the flowers are usually brought from Marseilles. Good Sicilian sulphur does not contain more than 3 per cent. of impurity, consisting chiefly of earths. The Louisiana sulphur the extraction of which is described on page 1204 enters commerce, having the purity of 99.9 per cent. Crude sulphur is employed by the manufacturers of sulphuric acid, and, as it is very variable in quality, it becomes important to ascertain its value. This may be done by drying a given weight of it and submitting it to combustion. The weight of the incombustible residue, added to that lost in drying, gives the amount of impurity.

Properties.—Sulphur is a non-metallic element, existing in several allotropic states. In its ordinary state it is a brittle solid, of a pale yellow color, permanent in the air, and exhibiting a crystalline texture and shining fracture. It has a slight taste, and a perceptible odor when rubbed. When pure its sp. gr. is about 2, but it varies a little in density in its different allotropic states. Occasionally, from impurity, its sp. gr. is as high as 2.35. Its atomic weight is 31.83, and its symbol S. It is a poor conductor of heat, and becomes negatively electric by friction. The melting point of sulphur varies with its allotropic state, which is readily altered by heat. Pure sulphur melts and sublimes at 114.5°C . (238°F). If heated above its melting point, it undergoes, in proportion to the heat applied, a progressive change, which will cause it, upon slow cooling, to solidify at a temperature lower than that at which it was melted; and if it be remelted it will be found to have a higher melting point than before. Melted sulphur is perfectly limpid, and of a bright yellow color. When sulphur is melted, and, after partial cooling, the crust formed on its surface is pierced, and the fluid portion poured out, it may be obtained in slender monoclinic crystals, constituting an allotropic condition of the element. This variety, however, gradually passes back into the more permanent variety found in nature. When sulphur is heated above its melting point, it becomes

deeper in color and less fluid. At 200° C. (392° F.) it has a deep brown color, and is so viscid that it cannot be poured from the containing vessel. If the temperature be still further increased, the sulphur resumes its fluidity, but retains its brown color. Finally, when the temperature reaches 448.4° C. (839° F.), it boils, forming a yellow vapor, and may be distilled. If melted sulphur, heated above 200° C. (392° F.), is suddenly cooled by being poured out into water, it becomes a reddish-brown plastic mass, with alteration of properties, called *soft sulphur* (*viscid sulphur*), which constitutes another allotropic variety, and is employed in taking impressions of medals, etc. This form of sulphur resumes the hard state, but not its original color, after the lapse of a few days, or suddenly if heated to 100° C. (212° F.). Sulphur is insoluble in water, but soluble in alkaline solutions, petroleum, rectified coal naphtha, the fixed oils, oil of turpentine and other volatile oils, alcohol and ether, chloroform, and carbon disulphide. One of its best solvents is carbon disulphide, from solution in which it crystallizes generally in rhombic octahedra, forms belonging to a different system from the monoclinic prisms obtained by crystallizing melted sulphur by cooling. Hence sulphur is said to be dimorphous. Eugène Pelouze has observed that the oils obtained by distilling the tar from gas works dissolve most sulphur at a temperature near their boiling point, and, if a saturated solution at this heat were to be allowed to cool, it would deposit sulphur in a crystalline form, and M. C. Wiedmann has suggested the application of this property to extraction of sulphur from native sulphur earths and ores, and from the residue of coal-gas works. (*A. J. P.*, June, 1871, p. 267.)

The allotropic states of sulphur have been studied chiefly by Brodie, Magnus and Weber, and Berthelot. These states are induced, for the most part, by heat, and are distinguished by the crystalline form of the sulphur, and by its solubility or non-solubility in carbon disulphide. *Insoluble sulphur* is the name given to that part of the soft sulphur which is left undissolved by the disulphide, amounting to between one-third and nearly one-half of the former. Brodie was unable to determine the melting point of this sulphur, but found it considerably above 120° C. (248° F.), or the melting point of prismatic sulphur. Flowers of sulphur contain about one-third of their weight of insoluble sulphur.

According to Marès, sulphur mixed with calcium carbonate, in the presence of the organic matters of the soil, is converted at first into hydrogen sulphide, then, under the influence of air and porous bodies, into sulphuric acid, finally into calcium sulphate, but Egidio Pol-lacer, on the contrary, thinks that sulphur in contact with calcium carbonate passes very readily into sulphuric acid, and then to calcium sulphate, independently of organic matters,

and without being preliminarily changed into hydrogen sulphide, and this opinion he supports by several experiments. (*J. P. C.*, Oct. 1874, p. 330.)

Sulphur takes fire at about the temperature of 148.8° C. (300° F.), and burns with a blue flame, combining with the oxygen of the air, and giving rise to sulphurous oxide, SO₂. The combinations of sulphur are numerous, and are among the most powerful chemical agents. It forms with oxygen four oxides, *sulphurous oxide* (sulphur dioxide), SO₂, *sulphuric oxide* (sulphur trioxide), SO₃, *sulphur sesquioxide*, S₂O₃, and *sulphur heptoxide*, S₂O₇. The first two of these oxides, by their union with water, form *sulphurous acid*, H₂SO₃, and *sulphuric acid*, H₂SO₄. There are also known *hyposulphurous acid*, H₂SO₂, the corresponding oxide of which is not known, and in combination *thiosulphuric acid* (frequently spoken of as *hyposulphurous acid*), H₂S₂O₃, *persulphuric acid*, H₂S₂O₈, and a series of acids, H₂S₂O₆, H₂S₂O₆, H₂S₂O₆, and H₂S₂O₆, called the *thionic series*. It forms with hydrogen, hydrogen sulphide (*hydrosulphuric acid* or *sulphuretted hydrogen*), and with the metals, various *sulphides*.¹ Some of the sul-

¹ *Ferri Sulphidum*, FeS; 87.33. *Ferrous Sulphide*. "Protosulphide of Iron, prepared by melting together Iron, in small pieces, and Sublimed Sulphur." *U. S.* 1870.

This was introduced into the U. S. Pharmacopœia of 1870 as the material from which hydrogen sulphide may be obtained, which, though not official, is in constant use as a reagent, and is often employed with great advantage in processes for isolating the active principles of medicinal substances. Ferrous sulphide is best prepared by bringing iron and sulphur into contact at a red or white heat. The following are the processes of the late Dublin and Edinburgh Pharmacopœias.

"Take of rods of Iron, of the size employed in the manufacture of nails, *any convenient number*. Having raised them to a strong red or white heat, apply them in succession by their heated extremities to sticks of Sulphur, operating so that the melted Sulphide, as it is formed, may drop into a stone cistern filled with water, and be thus protected from oxidation. The water being poured off, let the product be separated from the Sulphur with which it is mixed, and, when dried, let it be enclosed in a well-stopped bottle." *Dub.*

"An inferior sort, good enough, however, for many purposes, is obtained by heating one part of Sublimed Sulphur and three of Iron Filings, in a crucible, in a common fire till the mixture begins to glow, and then removing the crucible, and covering it until the action, which at first increases considerably, shall come to an end." *Ed.*

Iron and sulphur form a number of sulphides, such as ferrous sulphide, FeS, ferric disulphide, FeS₂ (this occurs in nature as *common* or *cube pyrites*), and ferric sesquisulphide, Fe₂S₃, which, while not found free in nature, occurs in magnetic pyrites, the formula of which is FeS₂ or 5FeS + FeS₂. When the sulphide is obtained by the application of solid sulphur to white-hot iron, the product corresponds with magnetic pyrites; but when procured by heating flowers of sulphur with an excess of iron filings, as directed in the above Edinburgh process, a protosulphide is formed mixed with metallic iron. When sulphur is applied to white-hot iron over water, the metal appears to become hotter, burns with scintillations in the vapor of the sulphur, and changes instantly to sulphide, which, being comparatively fusible, melts into globules; these drop into the water, which serves to extinguish them.

Properties.—Ferrous sulphide has a yellowish color and the metallic lustre. When obtained over water it is in the form of brownish-yellow globules having a somewhat crystalline texture. When pure it furnishes a yellow powder, and dissolves in dilute sulphuric or hydrochloric acid without leaving a residue of sulphur, and with the production of hydrogen sulphide free from admixture of hydrogen. As pre-

phides are analogous to oxy-acids, others to basic hydroxides; and these different sulphides, by combining with one another, form compounds which, from their analogy to salts, are called by Berzelius *sulphosalts*.

Sulphur, when obtained by roasting the native sulphide, sometimes contains arsenic, and is thereby rendered poisonous. Sicilian sulphur, being volcanic, is not subject to this impurity. The common English roll sulphur is sometimes made from iron pyrites, and is then prone to contain orpiment (*arsenic trisulphide*). This impurity may be detected by heating the suspected sulphur with nitric acid. The arsenic, if present, will be converted into arsenic trioxide, and the nitric solution, diluted with water, neutralized with sodium carbonate, and acidulated with hydrochloric acid, will give a yellow precipitate of arsenic pentasulphide with a stream of hydrogen sulphide. A precipitate may be more readily obtained from the nitric solution if, after neutralization, sulphurous acid be added, which will convert the arsenic acid into arsenous acid. This is more easily decomposed by the hydrogen sulphide, but the precipitate obtained will now be the trisulphide. Sulphur, when perfectly pure, is wholly volatilized by heat, and soluble without residue in oil of turpentine. According to Playfair, a solution of sodium nitro-prusside is a delicate test for the alkaline sulphides, producing with them a violet tint. Bailey of West Point, employed the same test for detecting sulphur in any compound. The substance suspected to contain it is fused with sodium carbonate, with the addition of carbonaceous matter if necessary. If sulphur be present it will be converted into sodium sulphide, and upon the addition of a small portion of the fused mass to a drop of the nitro-prusside the characteristic violet tint will be produced.

Sublimed sulphur, usually called *flowers of sulphur* (*flores sulphuris*),¹ is "a fine, yellow

pared, however, by the usual processes, it is not entirely soluble in dilute sulphuric acid, a portion of uncombined sulphur being left. The fused globules have the composition $5\text{FeS} + \text{FeS}_2$, or, according to some, $5\text{FeS} + \text{Fe}_2\text{S}_3$. This sulphide is employed solely as a pharmaceutical agent for the production of hydrogen sulphide. It yields this gas by reaction with diluted sulphuric acid.

Sulphuretted hydrogen is a colorless gas, with an odor like that of putrid eggs. Its sp. gr. is 1.1782. It saturates bases, with which it forms salts called sulphides.

¹*Ventilated (Dusted) Sulphur*.—Wacker gives the name "ventilated sulphur" to finely divided (dusty) sulphur, which is obtained by subjecting finely powdered sulphur to the action of a blower whereby the fine particles are carried into large compartments provided for the purpose. The operation must, however, be conducted in an atmosphere devoid as much as possible of oxygen (such as illuminating or fuel gas), since the finely divided sulphur is liable to cause explosion in the presence of oxygen. The product is pale yellow, resembles precipitated sulphur, and will pass through sieves of 200 meshes to the inch. Its extreme fineness renders it superior to the ordinary powdered or flowers of sulphur for many purposes for which these are commonly used, and particularly for spraying grape vines infected with the disease of the leaves called "oidium," for which ordinary flowers of sulphur is popularly employed in Italy. (*Ph. Centralh.*, July 4, 1901, 417.)

powder, having a slight characteristic odor, and a faintly acid taste. Insoluble in water; readily soluble in carbon disulphide; slightly soluble in absolute alcohol; more readily soluble in petroleum benzin, benzene, oil of turpentine, and many other oils; also in ether, chloroform, and in boiling aqueous solutions of alkali hydroxides. At about 115°C . (239°F .) it fuses to a yellow, mobile fluid, which upon further heating, becomes dark and viscid, until a temperature above 300°C . (572°F .) is reached, when it becomes a thin liquid boiling at 448°C . (838.4°F .). In the air it burns to sulphur dioxide, characterized by its odor, and by its blackening a strip of paper moistened with mercurous nitrate T.S. held in the gas. When agitated with water, the latter gives an acid reaction with litmus paper. The amount of residue left after volatilizing or burning a weighed portion of well-dried Sublimed Sulphur should not exceed 0.5 percent." *U. S.* "A slightly gritty powder of a bright greenish-yellow color, without taste and without odor. Under the microscope it is seen to consist of almost opaque irregular particles without any admixture of crystalline matter. It burns with a blue flame, forming sulphurous anhydride; and is entirely volatilized by heat. It should not have any action upon *litmus*. *Solution of ammonia*, agitated with it, and filtered, does not on evaporation leave any residue (absence of arsenium sulphide)." *Br.* It is always contaminated with a little sulphuric acid, which is formed at the expense of the oxygen of the air contained in the subliming chambers. Accordingly, it always reddens litmus, and, if the acid is present in considerable quantity, sometimes cakes. It may be freed from acidity by careful washing with diluted ammonia water. (See *Sulphur Lotum*.)

Uses.—Sulphur is laxative, diaphoretic, and resolvent. It is supposed to be rendered soluble by the alkali of the bile. Mialhe taught that it is carried into the circulation by the fatty matters in the alimentary canal which dissolve it. (*M. T. G.*, June, 1868, p. 642.) It evidently passes off by the pores of the skin, as is shown by the fact that silver carried in the pockets of patients under a course of it becomes blackened with a coating of sulphide. The stools which it occasions are usually semi-solid, and it is gentle in its operation, unless it contain a good deal of acid, when it may cause griping; the liability of the sublimed sulphur to contain acid renders it less eligible for exhibition than the washed sulphur, from which all acidity is removed. The diseases in which sulphur is principally used are *hemorrhoids*, *atonic gout*, *chronic rheumatism*, *chronic catarrh*, and *asthma*. It has also been given as an antiperiodic, being considered particularly applicable to cases in which the *apyrexia* is incomplete.

Applied locally, sulphur is a specific in *scabies*. It is sometimes applied as an air bath, in the form of sulphurous acid gas, the

head being protected from its effects.¹ It has been used to a considerable extent in *diphtheria*, the flowers being blown by means of a tube, or a little cone of paper like a lamp lighter, upon the fauces from four to six times a day. The external use of sulphur is strongly recommended by O'Connor of London, in *sciatica* and *chronic articular rheumatism*. The limb affected is covered with sulphur, and bandaged with new flannel, over which sheets of wadding are wrapped. The dressing should not be taken off for several days, as its earlier removal would interfere with the absorption of the sulphur, on which its curative effect depends. (*L. L.*, Am. ed., June, 1857, p. 507.) The dose of sulphur is from one to three drachms (3.9 to 11.6 Gm.), mixed with syrup or molasses, or taken in milk. It is often combined with potassium bitartrate, or with magnesia.

According to Hannon of Brussels, *soft sulphur*, recently prepared, possesses valuable therapeutic properties, not as a laxative, but as a stimulant to the circulation, lungs, and skin, far more active than ordinary sulphur. The dose of soft sulphur is from twenty to fifty grains (1.3 to 3.2 Gm.), given in the form of pill. It has also been successfully employed for filling the hollows of *carious teeth*. (*P. J.*, xvii. 330.) Sublimed sulphur has been used with extraordinary success in South Africa and the Philippines in the treatment of *amœboid dysentery*. It acts probably by killing the amœba. It may be given in divided doses up to two hundred grains (13 Gm.) a day.

Much sulphur is consumed in the arts, principally in the manufacture of gunpowder and of sulphuric acid.

Dose, one to three drachms (3.9 to 11.6 Gm.).

SULPHURIS IODIDUM. U. S., Br.

SULPHUR IODIDE

(sŭl'phŭ-ris i-ôd'î-dŭm)

Sulphur Iodatum; Ioduretum Sulfuris; Iodure de Soufre, *Fr.*; Jodschwefel, *G.*

* "Washed Sulphur, twenty grammes [or 308 grains]; Iodine, eighty grammes [or 2 ounces av., 360 grains]. Mix the Sulphur and Iodine thoroughly by trituration; introduce the mixture into a flask, close the orifice loosely, and, by means of a water-bath, gradually and with occasional agitation apply a heat not ex-

ceeding 60° C. (140° F.), until the ingredients combine and become of a uniformly dark color throughout. Then increase the heat to the boiling point of the water, so as to fuse the mass. Should any Iodine have sublimed and condensed on the glass, incline the flask so as to combine the Iodine with the fused mass, and then pour the latter upon a porcelain plate or other suitable cold surface. When it is cold break the product into pieces of suitable size, and keep them in a glass-stoppered bottle, in a cool place." *U. S.*

"Iodine, 4 ounces (Imperial) or 100 grammes; Sublimed Sulphur, 1 ounce (Imp.) or 25 grammes. Intimately mix the Sublimed Sulphur with the Iodine; heat the mixture gently in a loosely corked flask; when the mass becomes uniformly dark, increase the temperature so as to produce liquefaction; allow the product to cool in the flask. The flask should then be broken, and the solidified mass of Sulphur Iodide reduced to fragments, which should be kept in a well-closed vessel." *Br.*

Both of the official processes were derived from the French Codex. Though formerly official with the London and Dublin Colleges, it was omitted in the first British Pharmacopœia, to be resumed in that of 1898. The process simply effects a combination of the two elements by melting them together.

Properties.—Sulphur iodide is in "brittle masses of a crystalline fracture and a grayish-black, metallic lustre, having the odor of iodine and a somewhat acid taste. Almost insoluble in water; soluble in about 60 parts of glycerin; very soluble in carbon disulphide. Alcohol, ether, and a solution of potassium iodide dissolve the iodine, leaving the sulphur. Continued boiling with water vaporizes all of the iodine, leaving about 20 percent. of sulphur as residue. On exposing Sulphur Iodide to the air, it gradually loses iodine. On heating it, some iodine sublimes at first; at a somewhat higher temperature a sublimate is formed, containing both iodine and sulphur. At a still higher temperature, the whole is volatilized, leaving only a trace of residue. If 0.5 Gm. of finely pulverized Sulphur Iodide, together with 1 Gm. of potassium iodide, be dissolved in 20 Cc. of water (the sulphur separating), not less than 28 Cc. of tenth-normal sodium thiosulphate V.S. should be required for complete decolorization of the mixture, using starch T.S. as indicator." *U. S.* "A grayish-black solid substance, with a radiate crystalline appearance. It resembles iodine in smell, and in the property of staining the skin. Soluble in 60 parts of *glycerin*; insoluble in cold water. When boiled with water the iodine passes off in vapor, and the sulphur remains as an insoluble residue having about one-fifth of the weight of the Sulphur Iodide taken." *Br.* This compound is chemically regarded as *iodine disulphide*, I_2S_2 , or, as sometimes stated, *sulphur subiodide*. Its solution in glycerin would probably prove useful, in some cases, as a

¹ *Sulphur candles* are now furnished by manufacturers, and are made by inserting wicks into melted sulphur contained in a can; as the sulphur cools, the wicks retain an upright position, and to obtain the effects of sulphurous acid gas it suffices to light the wicks and permit the fumes to come in contact with moist air. They are used for disinfecting apartments, etc.

substitute for the ointment of this iodide. It is rapidly decomposed, when in a state of powder, upon the addition of several of the volatile oils, violet vapors of iodine being evolved, and the odor of sulphur perceived. (G. W. Patterson.) Sulphur iodide has been very usefully employed as an external remedy in various skin diseases, such as *tinea capitis*, *lupus*, *lepra*, etc., applied in the form of ointment. (See *Unguentum Sulphuris Iodidi*.) Internally, it has been used with alleged great advantage in human glanders. (Bourdon of Paris, *Ann. Thér.*, 1853, 239.)

SUMBUL. U. S. (Br.)

SUMBUL [Musk-root]

(sūm'būl)

"The dried rhizome and root of an undetermined plant, probably of the family *Umbelliferae*." U. S. "The dried transverse slices of the root of *Ferula Sumbul*, Hook." Br.

Sumbul Radix, Br.; *Racine de Sumbul* Fr.; *Sumbulwurzel*, *Moschuswurzel*, G.

Under the name of *sumbul* or *jatamansi*, a root has long been used in India, Persia, and other parts of the East, as a perfume, an incense in religious ceremonies, and medicinally. It was the root of a then unknown plant, supposed to be umbelliferous, and, from the character of the root, to grow in low wet places. The plant is said to inhabit no part of British India, but the regions to the north and east of it, as Nepaul, Bootan, Bucharia, etc. The root is taken northward to Russia, and reaches the rest of Europe through St. Petersburg. The physicians of Moscow and St. Petersburg were the first to employ it on the continent of Europe. Granville first introduced it to the notice of the profession in Great Britain and in this country. It has also been imported into England from India, whither it was brought from a great distance. The plant which was recognized by the U. S. P. 1890 as the source of the sumbul of the day was the *Ferula Sumbul*, Hooker fil., *Bot. Mag.* (1875) t. 6196.

Euryangium Sumbul, Kauffmann, *Nouv. Mém. Soc. Imp. Nat. de Moscou* (1871), xiii. t. 24, 25.—This plant was first discovered by the Russian Fedschenko in 1869, growing at an elevation of 3000 feet in the mountains which separate Russian Turkestan from Bucharia. In 1871 it was described by Kauffmann, who erected a new genus on characters dependent upon the enormous size of the vittæ in the immature fruit. The plant has been cultivated in the Moscow botanical gardens, and, less successfully, at Kew, and it has been found that the vittæ almost disappear in ripening, and do not afford a good generic character. The plant is described as an enormous umbellifer, reaching a height of eight feet, and hav-

ing a solid, cylindrical, slender stem, which in the upper part gives origin to about twelve slender divaricate branches. The root-leaves are two and a half feet long, with short, channelled, broadly dilated, completely clasping petioles. They are triangular in outline, tripinnate, with the alternate divisions fine. The stem-leaves rapidly decrease in size until they become mere sheathing bracts. The flowers are polygamous, the fruit from three-eighths to one-half inch long by one-fourth inch wide; the mericarps oblong-oval, dorsally much compressed, thin, with three faint, thread-like, dorsal ridges; no dorsal vittæ, and commissural ones collapsed. The sumbul of the present world-markets differs so materially from that formerly seen that the U. S. P. revisers have adopted the suggestion of Holmes that it is a distinct drug of unknown botanical origin. J. E. Aitchison states (*Tr. Linn. Soc.*, ser. 2, *Bot.*, 69) that the root of *Ferula suaveolens*, which has only a faint musky odor, is one of the kinds exported from Persia to Bombay by the Persian Gulf.

Properties.—Sumbul formerly occurred in the markets in transverse slices 1 to 5 inches in diameter and an inch or more in thickness, with a dark, thin bark, a light, spongy parenchyma and dirty-brown surfaces, showing under the lens an abundant resinous exudation. Further, the taste, at first feebly sweetish, became after a time bitterish and balsamic, but not disagreeable, and a strong aroma was developed under mastication, diffusing itself with a sensation of warmth through the mouth and throat and rendering the breath fragrant. The musky odor was very strong. The sumbul of the present day differs from that just described, in being smaller, often in cylindrical pieces, and having a firmer structure and less decided odor, and also, according to Holmes, often a branched rootstock. It is officially described as "in transverse segments, of variable length and rarely exceeding 10 Cm. in diameter; externally dusky brown, annulate, longitudinally wrinkled, or with a smooth, silver-gray periderm; fracture short-fibrous, light yellow or brownish-yellow, spongy, porous, with numerous brownish-yellow resin reservoirs, and irregular, easily separable fibres; bark about 0.5 Mm. thick; odor strong, musk-like; taste bitter." U. S.

The root has been analyzed by Reinsch and other German chemists, and found to contain volatile oil, two balsamic resins, one soluble in alcohol, the other in ether; wax, gum, starch, a bitter substance soluble in water and alcohol, and an acid which was named *sumbulic acid*, but which Riecker and Reinsch showed to be *angelic acid*, $C_8H_8O_2$, accompanied by a little valeric acid, $C_5H_{10}O_2$. Solution of potassium hydroxide is said to convert the resin into the potassium salt of an acid called *sumbulamic*, but which has not been sufficiently investigated. The musk-like odor seems to be connected with the balsamic resins, and probably depends on some principle associated

with them not yet isolated. The volatile oil, of which 0.33 per cent. is yielded by distillation, has a taste like that of peppermint. On dry distillation it yields a bluish oil which contains *umbelliferone*. Philip H. Utech (*A. J. P.*, 1893, p. 465) has extracted and purified the resin soluble in alcohol. He obtained it as a soft, whitish, translucent resin which, on drying at 110° C., yielded a clear, transparent, amber-colored product having a bitter taste and the aromatic odor of the root. It constituted 6.1 per cent. of the drug. J. H. Hahn (*Proc. Penna. Ph. Assoc.*, 1896, 75) found 17.25 per cent. of fixed oil in sumbul.

Uses.—Sumbul is a nervous stimulant, belonging to the class of antispasmodics, and was originally used by the Russian physicians as such, and also in asthenic cases of *dysentery* and *diarrhæa*. It has been employed to a considerable extent in this country in *amenorrhæa*, *hysteria*, *chlorosis*, and other allied diseases of the female sex, as an adjuvant to other remedies. The best preparations for use are the tincture and the fluid and solid extracts. There has been no great precision as to dose, but from one-half drachm to two drachms (2.0 to 7.7 Gm.) of the root or its equivalent may be given at a time.

Murawieff of Russia, prepares the resin, which he considers to be the active principle, by macerating the root first in water, and then in a solution of sodium carbonate, washing it well with cold water, drying it, treating it with alcohol, filtering the tincture, adding a little lime and again filtering, separating the lime by sulphuric acid, agitating with animal charcoal, again filtering, distilling off nearly all the alcohol, mixing the residuum with water, driving off the remaining alcohol, and, finally, washing the precipitate with cold water, and drying it. The resin thus obtained is whitish, translucent, softening between the fingers, combustible without residue, of an acid taste, and an aromatic odor, like that of the root. Murawieff gives it in the *dose* of a grain or two (0.065 or 0.13 Gm.), in the form of pill, three or four times a day, with or without opium, and has found it useful in *chronic bronchitis* and *pneumonia* slow of resolution, in the *moist asthma* of old, anæmic, and scorbutic patients, in *atonic dysentery*, *leucorrhæa*, *hypochondriasis*, and *hysteria*. (*Dublin Q. J.*, Feb. 1855, p. 252.) Procter has published a formula for a fluidextract, of which the dose is from fifteen minims to a fluidrachm (0.9 to 3.75 Cc.). (*A. J. P.*, xxvii. 233.) Half an ounce of a tincture produced narcotic symptoms, such as confusion of the head, a tendency to snore, even when awake, feelings of tingling, etc., with a strong odor of the medicine from the breath and skin, which continued for a day or two and gradually passed off. (*N. R.*, Oct. 1874, p. 309.)

Dose, one-half drachm to two drachms (2.0 to 7.7 Gm.).

SUPPOSITORIES

(sup-pōs-ī-tō'ri-ā)

Suppositoires, *Fr. Cod.*; Suppositoria, *P. G.*; Suppositorien, *Stuhlzäpfchen*, *G.*; Supositorios, *Sp.*

Suppositories are solid bodies usually intended to be introduced into the rectum with a view either of evacuating the bowels by irritating the mucous membrane of the rectum, or of producing a specific effect on the neighboring parts or on the system at large. Suppositories are also made for vaginal or urethral administration. They fulfil the same indications as enemas, and are sometimes preferable from the facility of their application, and, when the object is to produce the peculiar effect of a medicine, from the smallness of their bulk, which facilitates retention. Their form may be cylindrical, conical, or spherical, the last being preferable when the bulk is small, or they may be in the shape of the modified cone with a tapering base, as recommended by H. S. Wellcome. (*Proc. A. Ph. A.*, 1893, p. 103.) They should be of such a consistence as to retain their shape, but so soft as to incur no risk of wounding the rectum. For laxative purposes the suppository may be from one to three inches long, and about as thick as a common candle; with a view to the specific effects of medicines it should be considerably smaller, as in this case it is important that the medicines should be retained and the irritative influence of distention avoided. Soap is not unfrequently employed in this way as a laxative. A piece of solidified molasses (molasses candy) is sometimes preferred. To increase the purgative effect, and at the same time act on the uterine function, aloes may be added to the soap. A. B. Taylor of Philadelphia, in 1852 called attention to cacao butter as the best base for suppositories, having more exactly the requisite degree of consistence and fusibility than any combination of suet, spermaceti, wax, etc., that could be employed. (*A. J. P.*, 1852, p. 211.) Experience has proved the correctness of his views. It has been thought necessary to use wax, spermaceti, or some other substance having a comparatively high fusing point, in order to render the suppository sufficiently firm. Continued experience has, however, demonstrated that, except in the warmest weather, or in the case of camphor, phenol, the essential oils, and similar medicinal substances, even the commercial cacao butter will suffice. It is said that cacao butter is usually adulterated with some other fat which melts at a low temperature, and that if a pure article can be obtained any substance to increase its hardness is never required. When such a material is employed, wax is usually selected, although cetaceum is preferable. If not more than 10 per cent. of the spermaceti is added, the value of the suppository is not very materially affected, although it melts more slowly, and con-

sequently requires a longer time to act, than when the butter of cacao is used alone. Suppositories containing a considerable percentage of wax melt so slowly in the rectum as to be comparatively useless, or they may fail altogether to soften down, and be finally passed from the anus unchanged. A very good method of mixing the oil of theobroma with the hardening material is by grating with an ordinary tin grater, such as used in kitchens, and mixing the coarse powders before melting, and W. G. Ewing has proposed rubbing the powders and the medicinal substance in a mortar together, dividing the plastic mass, and shaping it with the fingers. It is better to shape them with a spatula, and roll them upon a pill tile with a little lycopodium. This plan, although having its advantages, is, however, not equal to the official one of melting the ingredients and running them into moulds. Extemporaneous moulds, made by rolling paper into cones about an inch long, may be used, but are much less convenient than permanent metallic moulds. The tendency of the hardened suppositories to adhere to the moulds may be overcome more or less perfectly by dusting the moulds with lycopodium powder, or greasing them well with olive oil, but it is far better to rely upon the natural contraction of the mass, caused by thoroughly cooling the moulds. Wm. B. Addington (*A. J. P.*, 1873, p. 257) advises lining the moulds with tin foil. The difficulty may also be met by the use of moulds that open lengthwise, which are now used almost exclusively in preference to individual moulds, and Chas. E. Dwight commends very highly the substitution of plaster of Paris moulds¹ for the metallic ones commonly employed. The mould must be very cold, so as to chill the melted liquid at once and prevent any separation of its ingredients by gravity. It has been proposed to condense the powdered ingredients of suppositories in a cold mould. (*A. J. P.*, 1875, p. 79.) It has also been recommended to form the excipient into the required shape, and then, while it is still soft, make an excavation from the base upward, into which the medicine may be introduced, and afterwards en-

closed by a little of the cacao butter. But, as one of the objects of the excipient is an equable diffusion of the medicine, to prevent irritation, this method would be inapplicable to substances in any degree locally irritant.

J. Percy Remington has devised a suppository mould made of soft vulcanized rubber, it is used in the same manner as that employed for a metal mould, the advantage being mainly the facility of removal when the suppository is cold, a slight pressure with a twisting motion causes the soft rubber mould to open, and the suppository to drop out easily. (*Proc. New Jersey Pharm. Association*, 1906.)

The weight—i.e., the size—of suppositories should vary according to the purposes for which they are employed. When they are to be used for infants and children, they should weigh from five to ten grains. The Br. Pharm., in conformity with the recommendation of H. B. Brady (*P. J.*, 1866, p. 544; 1868, p. 321; and 1871, pp. 193, 488, 563),² adopts the weight of fifteen grains. Experience has shown this to be the most useful size, and the U. S. P. 1880 adopted it, but the U. S. P. (8th Rev.) directs the weight to be thirty grains.

The U. S. P. (8th Rev.) directs as follows: "Suppositories are solid bodies of various weights and shapes, adapted for introduction into the different orifices of the human body, and melting readily at blood heat. The vehicles usually employed are Oil of Theobroma, Glycerinated Gelatin, or Sodium Stearate. For suppositories made with Oil of Theobroma the following general processes may be employed: Take of the Medicinal Substance, *the prescribed quantity*; Oil of Theobroma, *grated, a sufficient quantity*. Reduce the Medicinal Substance, if dry, to a very fine powder, or, if an extract, soften it with an appropriate liquid, then mix it thoroughly in a mortar with about an equal weight of grated Oil of Theobroma, and incorporate the remainder of the Oil of Theobroma until a homogeneous, plastic mass is obtained, adding, if necessary, a small quantity of Expressed Oil of Almond. Roll the mass on a graduated tile until a cylinder of the proper length is formed, divide this into the required number of equal parts, and with a spatula, or other convenient mechanical aid, form them into the desired shape. If the process of fusion is preferred, mix the Medicinal Substance with about an equal weight of grated Oil of Theobroma, as above directed, then thoroughly incorporate it with the remainder of the Oil of Theobroma, previously melted by a gentle heat, in a suitable vessel provided with a lip; then allow it to cool to about 38° C. (100.4° F.), and, when the mixture begins to congeal, pour it immediately into suitable well-cooled moulds. Keep the moulds at a freezing temperature until the suppositories have hard-

¹ Dwight makes these moulds in the following manner: Into a pasteboard box, about six inches long and two wide, pour liquid plaster of Paris, of the consistency of thick cream until half full. Having prepared six well-moulded suppositories of wax, immerse them in the soft plaster half their diameters, with their large end close to the edge of the box, in a row, and at a uniform distance. When the plaster has set, gently remove the wax, and with a knife smooth off the surface and trim the edges of each mould sharp, and between each depression made by the wax suppository dig a small cavity about the size and shape of a small steel pen cut through the centre. When the face has become hard, grease it with linseed oil or lard, replace the wax suppositories, and raise the edges of the box by wrapping heavy paper around it, which will extend about another inch above the surface of the face; pour a portion of the plaster, equal to the first, gently over the greased surface until it is about one inch deep. When hard, separate the parts carefully, trim the edges, and boil for an hour in linseed oil, which will prevent the adhesion of the substance to be moulded. To be substantial, the plaster must be mixed thin and well stirred.

² The papers of Brady upon the subject of suppositories may be consulted with advantage; also a series of articles by several other authors in *A. J. P.*, 1871.

ened and are ready to be removed. For suppositories containing hydrated chloral, phenol, their derivatives, or substances which soften the vehicle, raise the melting point of the Oil of Theobroma by the addition of from ten to fifteen percent. of spermaceti, but the melting point must not be raised above 37° C. (98.6° F.).

For suppositories made with Glycerinated Gelatin the following process may be used: Take of the Medicinal Substance, *the prescribed quantity*; Glycerinated Gelatin, Glycerin, Water, each, *a sufficient quantity*. Mix the Medicinal Substance, if solid and soluble in Water or Glycerin, or if a miscible liquid, with a little Water, and add sufficient Glycerin to make the weight of the mixture one-half that of the finished mass. Then thoroughly incorporate it with an equal weight of melted Glycerinated Gelatin, and pour it at once into suitable moulds which have been greased with a small quantity of petrolatum. Cool the mould thoroughly before removing the suppositories. Moulds for urethral suppositories should be warmed sufficiently before pouring the mass to facilitate the proper filling of the mould. Suppositories having a firmer consistence may be prepared by substituting Mucilage of Acacia for a portion of the Water or Glycerin. If the Medicinal Substance be insoluble in Water or Glycerin, thoroughly levigate it in a warm mortar with a sufficient quantity of Glycerin to make the weight of the mixture one-half that of the finished mass. Then thoroughly incorporate it with an equal weight of melted Glycerinated Gelatin, and pour it into suitable moulds as above directed. With bulky powders about one-half of the Glycerin may be replaced with Water before levigation. Glycerinated Gelatin suppositories should be protected against the effects of heat and moisture and dry air by keeping them in tightly closed containers in a cool place.

Rectal Suppositories should be cone-shaped or spindle-shaped, and when made from Oil of Theobroma should weigh about *two grammes*.

Urethral Suppositories (Bougies) should be pencil-shaped, pointed at one extremity, and either *seven centimeters* in length, weighing about *two grammes*, or *fourteen centimeters* in length, weighing about *four grammes*, when made with Glycerinated Gelatin. If prepared with Oil of Theobroma they should weigh about one-half the above quantities.

Vaginal Suppositories should be globular or oviform in shape, and weigh about *ten grammes* if made with Glycerinated Gelatin, and about *four grammes* if made with Oil of Theobroma." U. S.

The U. S. Pharmacopœia gives no detailed formulæ for suppositories, except in one case, *Suppositoria Glycerini*. Opium, or some one of its preparations, is very advantageously administered in the form of a suppository, in cases of irritation of the rectum, urinary passages, or genital apparatus. The other nar-

cotics may be used in the same way, and indeed almost any other medicine, in reference to its effects on the system, provided the quantity be not too large and the effects not too pronounced. Tannic acid or other local remedies may also be very appropriately employed in this way in cases of *prolapsus* or other affections of the rectum or anus. The dose may in general be one and a half times that of the medicine given by the mouth.¹

The inventive genius of pharmacists has been industriously applied to the construction of suppository moulds, and there are now many varieties; the principle is much the same in all, however, but for convenience they may be classed as follows: 1. Individual moulds; these were among the first to be used. Half a dozen conical, hard-metal moulds are retained in an upright position in a tray containing ice-water, or made of paper, tin-foil, etc. (See *A. J. P.*, 1861, p. 5; 1863, p. 228; 1867, p. 121; 1868, p. 52; 1870, pp. 296, 392; *Proc. A. Ph. A.*, 1902, 501.) 2. Moulds which consist of two solid pieces of metal, hinged or temporarily joined, so that when the suppository is thoroughly cooled the parts may be separated and the suppository dropped out. (See *A. J. P.*, 1871, pp. 488, 563; 1874, pp. 192, 246; 1875, pp. 98, 202; 1877, p. 569; 1879, pp. 184, 277; and *Proc. A. Ph. A.*, 1893, p. 103; 1902, 757.) 3. Soft rubber moulds. (See *Proc. New Jersey Pharm. Assoc.*, 1906.) 4. Moulds designed to be used through compression, more or less powerful. (*N. R.*, June, 1879, Jan. and March, 1880; also *Proc. A. Ph. A.*, 1897, p. 442.)

¹ *Medicated Pessaries*, which were recommended by J. Y. Simpson of Edinburgh, so closely resemble suppositories, so far as pharmacy is concerned, as to justify a mention of them in this place. All that has been said of the materials out of which suppositories are made, and the mode of preparing them, is equally applicable to medicated pessaries. The latter, however, are considerably larger, generally weighing one or two drachms. They differ also from suppositories in the purposes to which they are applied, being used for local effect, in allaying pain, checking discharge, acting as alternative to contiguous parts, etc. For important pharmaceutical details, see an article in *A. J. P.*, 1868, p. 223.

Urethral and Vaginal Suppositories. Medicated Bougies.—These articles, which are exceedingly useful for the purpose of exerting a local action upon the urethra or the neck of the bladder in cases of inflammation, pain, or spasm, may be made in the same manner as ordinary suppositories, except in regard to size. The vaginal suppository should be about two to two and a half inches long, and three-quarters of an inch in diameter at the base. Urethral suppositories should be cylindrical, with a conical point, and about one-fourth of an inch in diameter; their length should vary according to circumstances. They should never contain wax or other substance which does not melt readily and certainly at the temperature of the body, and which might, by a possible mishap, become the nucleus of a calculus. When it is desired to reach any considerable length of the urethra, the requisite toughness may be obtained, as suggested by Jos. L. Lemberger (*A. J. P.*, 1872, p. 166), by using a mould like an old fashioned candle mould, with a candle wick running through and projecting some distance from it. When a suppository so made is used, of course the free end of the wick should be secured with sticking plaster or a drop of collodion externally, and after the requisite period of contact the whole be pulled out. These are now largely made from gelatin, water, and a little glycerin. (See Mitchell's paper, *A. J. P.*, 1878, 108; also *P. J.*, 1895, 537; 1896, 484; and *Proc. A. Ph. A.*, 1894, 814.) For *Agar-Agar Suppositories*, see *A. J. P.*, 1895, 599; also *Proc. A. Ph. A.*, 1897, 443.

SUPPOSITORIA ACIDI CARBOLICI. Br.**PHENOL SUPPOSITORIES**

(sup-pōs-i-tō'ri-ā āç'i-dī cār-bōl'i-cī)

Carbolic Acid Suppositories; Suppositoires d'acide Phénique, *Fr.*; Phenol-suppositorien, *G.*

"Phenol, 12 *grains* or 0.8 gramme; White Beeswax, 24 *grains* or 1.6 grammes; Oil of Theobroma, melted, a *sufficient quantity* to form, with the Phenol and Beeswax, a mixture which will fill twelve suitable moulds, each capable of holding *fifteen to sixteen grains* or about one gramme of Oil of Theobroma. Dissolve the Phenol in the Oil of Theobroma and Beeswax previously melted together at a low temperature, and pour the mixture into the moulds; or let the mixture cool and then divide it into twelve equal parts of a conical or other convenient form for a suppository. Each of these Suppositories contains 1 *grain* or 0.067 gramme of Phenol." *Br.*

These suppositories are intended to furnish a means of administering phenol by the rectum; the wax is needed to offset the tendency to liquefy.

SUPPOSITORIA ACIDI TANNICI. Br.**TANNIC ACID SUPPOSITORIES**

(sup-pōs-i-tō'ri-ā āç'i-dī tăn'n'i-cī)

Suppositoires de Tannin, *Fr.*; Tanninsuppositorien, Tannin-Stuhlzäpfchen, *G.*

"Tannic Acid, 36 *grains* or 2.4 grammes; Oil of Theobroma, a *sufficient quantity* to form with the Tannic Acid a mixture which will fill twelve suitable moulds, each capable of holding *fifteen to sixteen grains* or about one gramme of Oil of Theobroma. Melt the Oil of Theobroma; triturate the Tannic Acid intimately with a little of the Oil, and add to the remainder; stir well; as the mixture begins to thicken pour it into the moulds; or let the mixture cool and then divide it into twelve equal parts of a conical or other convenient form for a suppository. Each of these Suppositories contains 3 *grains* or 0.2 gramme of Tannic Acid." *Br.*

As it is hardly conceivable that a rectal dose of less than five grains should be wanted for the adult, the U. S. preparation of 1870 was of the latter strength (*i.e.*, five grains). The benzoated lard formerly added by the British authorities with a view of preventing rancidity has been omitted. The remedy is especially applicable to cases of *piles* and *prolapsus of the rectum*.

SUPPOSITORIA BELLADONNÆ. Br.**BELLADONNA SUPPOSITORIES**

(sup-pōs-i-tō'ri-ā bēl-lā-dōn'næ)

Suppositoires de Belladone, *Fr.*; Belladonnasuppositorien, *G.*

"Alcoholic Extract of Belladonna, 18 *grains* or 1.2 grammes; Oil of Theobroma, a *sufficient*

quantity for twelve suppositories. Proceed as directed for Tannic Acid Suppositories. Each of these Suppositories contains, approximately, one-sixtieth *grain* or 0.001 gramme of the alkaloids of Belladonna Root." *Br.*

SUPPOSITORIA GLYCERINI. U. S., Br.**SUPPOSITORIES OF GLYCERIN**

(sup-pōs-i-tō'ri-ā glyç-e-rī'nī)

Suppositoires de Glycerin, *Fr.*; Glycerinsuppositorien, *G.*

* "Glycerin, *thirty grammes* [or 1 ounce av., 25 grains]; Monohydrated Sodium Carbonate, *one-half gramme* [or 7.7 grains]; Stearic Acid, *two grammes* [or 31 grains]; Water, *five cubic centimeters* [or 81 minims], to make *ten rectal suppositories*. Dissolve the Monohydrated Sodium Carbonate in the Water and add it to the Glycerin, contained in a dish, on a water-bath; add the Stearic Acid, and heat the mixture carefully until carbon dioxide ceases to be evolved, and the liquid is clear. Then pour the melted mass into suitable moulds, remove the suppositories when they are completely cold, and preserve them in tightly stoppered glass vessels." *U. S.*

"Gelatin, cut small, $\frac{1}{2}$ ounce (Imperial) or 14.2 grammes; Glycerin, $2\frac{1}{2}$ ounces (Imp.) or 71.0 grammes; Distilled Water, a *sufficient quantity*. Place the Gelatin in a weighed evaporating dish with sufficient Distilled Water to cover it; let it stand for two minutes; pour off the excess of Distilled Water; set aside until the Gelatin is quite soft; add the Glycerin; dissolve on a water-bath; evaporate until the mixture weighs *fifteen hundred and sixty-three grains* or one hundred and two grammes. Pour the product into suppository moulds having capacities equal to *thirty, sixty, or one hundred and twenty grains* or two, four, or eight grammes of the Suppository, or of such other capacities as may be required. Each of these Suppositories contains 70 per cent. of Glycerin." *Br.*

These were official for the first time in the U. S. P. 1890. Glycerin suppositories have come into extensive use, the object being to introduce glycerin into the rectum with a minimum amount of other ingredients. Stearic acid was selected on account of its forming with sodium carbonate the hardest soap attainable, thus permitting the introduction of a suppository containing at least 90 per cent. of glycerin, the water added to dissolve the monohydrated sodium carbonate and some of the glycerin being evaporated during the manipulation. A small quantity of water is used in the process to facilitate the reaction; this is driven off subsequently by heat. This process was perfected by J. P. Remington. (See *Practice of Pharmacy*, 4th ed., 1244.) The British method, on account of the use of gelatin, permits the presence of only 70 per cent. of glycerin, the suppository not being firm enough for con-

venient application, and, in addition, the method of hydrating the gelatin is faulty. (*C. D.*, 1898, 831.) Instead of wrapping the suppositories in tin foil it will be found more satisfactory to insert each one in a small glass tube of the proper size, corked at both ends. Some protection from the moisture in the air is necessary because of the hygroscopic character of glycerin. (See *P. J.*, 1893, 63; 1895, 182; *Am. Drug.*, 1894, 91; *West. Drug.*, 1894, 141; *A. J. P.*, 1895, 599.)

Uses.—Glycerin suppositories are very much used to produce fecal discharges in *constipation*. They act by locally irritating the mucous membrane of the rectum, and are often very efficient, though never really purgative. As an occasional remedy they are useful, but their habitual employment is probably injurious to the mucous membrane.

SUPPOSITORIA IODOFORMI. Br.

IDOFORM SUPPOSITORIES

(sup-pōs-i-tō'rī-ā i-ōd-ŏ-fō'r'mī)

Suppositoires d'Iodoforme, *Fr.*; Iodoformsuppositorien, *G.*

"Iodoform, 36 *grains* or 2.4 grammes; Oil of Theobroma, a *sufficient quantity* for twelve suppositories. Proceed as directed for Tannic Acid Suppositories. Each of these Suppositories contains 3 *grains* or 0.2 gramme of Iodoform." *Br.*

These suppositories are valuable in cases of rectal inflammation and irritation. It is often possible by their use in *dysentery* to avoid the use of opium to a greater or less extent.

SUPPOSITORIA MORPHINÆ. Br.

MORPHINE SUPPOSITORIES

(sup-pōs-i-tō'rī-ā mör-phī'næ)

Suppositoires de Morphine, Suppositoires morphinés, *Fr.*; Morphiumsuppositorien, Morphin-Stuhlzäpfchen, *G.*

SYRUPI.

SYRUPS

(syr-rā'pī)

Sirops, *Fr. Cod.*; Sirupi, *P. G.*; Sirupe, *G.*; Siruppl, *It.*

Syrups are concentrated solutions of sugar in aqueous fluids, either with or without medicinal impregnation. When the solution is made with pure water, it is named *syrup* or *simple syrup*; when made with water charged with one or more medicinal agents, it is called in general terms a *medicated syrup*, and receives its special designation from the substance or substances added.

Medicated syrups are usually prepared by dissolving sugar in vegetable infusions, vinegars, decoctions, expressed juices, fermented liquors, or simple aqueous solutions. When the active matter of the vegetable is not readily soluble in water, is associated with soluble matter which it is desirable to avoid, or is volatilized or decomposed by a heat of 100° C. (212° F.), it is sometimes extracted by diluted alcohol, the spirituous ingredient of which is subsequently driven off. Medicated syrups are also occasionally prepared by adding a tincture to simple syrup and evaporating the alcohol. Another and a better mode of effecting the same object, when aromatic or other volatile substances are concerned, is to mix the tincture with sugar in coarse powder, expose the mixture to a very gentle heat or to the sun till the alcohol has evaporated, and then prepare the syrup from the impregnated sugar by dissolving it in the requisite proportion of water. Since the introduction into use of the process of percolation, or filtration by displacement, it has been applied very advantageously to the preparation of various syrups, especially those made from vegetables of which the active principle is injured or dissipated by decoction. But, unless the operator be at once skilful and careful, there will be danger of imperfectly extracting the active matters, and thus making a feeble preparation. One important practical rule is, when the liquid obtained by percolation requires concentration, to set aside the first portions of filtered liquor, which are usually strongly impregnated, and to subject only the subsequent weaker portions to evaporation. For the mode of properly conducting this process the reader is referred to page 1216.

The quality and quantity of the sugar employed are points of importance. Refined sugar should always be used, as it saves the necessity

of clarification, and makes a clearer and better-flavored syrup than the impure kinds. The U. S. Pharmacopœia simply directs sugar, but explains that it is the purified or refined sugar which is indicated by that term. In relation to the quantity of sugar, if in too small proportion, fermentation is apt to occur; if too abundant, crystallization. The proper proportion is about two parts to one of the liquid. A somewhat smaller quantity will answer where an acid, such as lemon juice or vinegar, is used.

As it is desirable, in many instances, that the active matters should be in as concentrated a state as possible in the syrup, it is often necessary to evaporate a large proportion of the aqueous fluid in which they are dissolved. This may be done either before the addition of the sugar or afterwards. In either case care is requisite not to apply a heat too great or too long continued, lest the active principles should be injured. When these are very volatile or easily decomposed by heat, it is expedient to dispense with concentration altogether. Some substances which are volatilized or decomposed at the temperature of boiling water remain fixed and unaltered at that which is necessary for the evaporation of alcohol. These, as before observed, may be dissolved in diluted alcohol, and the concentration effected by evaporating the spirituous part of the solvent. Independently of the injury which the medicinal ingredient of the syrup may sustain, the syrup itself is apt to become brown by a continued application of heat, even when the degree is not excessive. It is recommended, therefore, that syrups which admit of concentration should be boiled briskly over a lively fire, so as to accomplish the object as quickly as possible. It is important to be able to ascertain positively when syrups have attained the due consistence. An operator skilled in their preparation can judge with sufficient accuracy by various familiar signs,—such as the slowness with which the parts of a drop of syrup coalesce, when previously separated by the edge of a blunt instrument, and the receding of the last portion of each drop, when the syrup, after being cooled, is poured out drop by drop. A pellicle forming upon the surface of the syrup when it cools indicates that it has been boiled too much.

These signs, however, are not to be relied on, except by those who have acquired much experience. The proper point of concentration is best ascertained by the use of that variety of Baumé's hydrometer called a *saccharometer*,—an instrument very useful to those making syrups upon the large scale. This should stand at 30° in boiling syrup (30½° in hot weather), and at 35° in the syrup when it is cool. Another very accurate, though less ready, method is to ascertain the sp. gr. by weighing a portion of the liquid. Syrup, when boiling, should have a sp. gr. of about 1.261; when cold, of about 1.317. Thomson and Duncan are in error in giving the proper sp. gr. of cold

syrup as 1.385. We found that of a specimen of simple syrup, made with two pounds and a half of sugar to a pint of water, as directed in former editions of the U. S. Pharmacopœia, to be 1.326 at 68° F.; but this strength is rather too great for practical convenience in cold weather. In the syrup now official it is only 1.313 at 25° C. (77° F.). A third method of ascertaining the proper point of concentration is by the thermometer, which, in boiling syrup of the proper consistence, stands at 105° C. (221° F.). This indication is founded on the fact that the boiling point of syrup rises with the increase of its density.

When carefully prepared with the best double refined sugar, syrups usually require no other clarification than to remove any scum which may rise to their surface upon standing, and to pour them off from any dregs which may subside. But, as the sugar employed is seldom free from impurities, it may be best, as a rule, to remove the scum as it rises during the heating process, and to strain the syrup while hot through muslin or flannel. Should syrups at any time lack the due degree of transparency, they may be filtered through paper if a hot water funnel is used, or, when likely to be injured by this treatment, may be clarified by means of the white of egg or animal charcoal, as mentioned under the head of *Syrupus*. But the active vegetable principles are so apt to be absorbed by the charcoal along with the impurities that this agent should be used with caution. The vicious habit practised by sugar refiners of "blueing" sugars by the use of ultramarine and other coloring agents cannot be too strongly deprecated. (See *A. J. P.*, 1901, 119.)

The medicated syrups are liable to undergo various alterations, according to their nature and mode of preparation. The acid syrups, when too much boiled, often let fall a copious white deposit, which is a saccharine matter analogous to the sugar of grapes, produced by the action of their acid upon the sugar. Even at ordinary temperatures, acids slowly convert common sugar into grape sugar, which, being less soluble than the former, is gradually deposited in the form of crystalline grains. Syrups containing too little sugar are subject to the vinous fermentation, in consequence of the presence of matters which act as a ferment. Those which contain too much, deposit a portion in the crystalline state, and the crystals, attracting the sugar remaining in solution, gradually weaken the syrup, and render it liable to the same change as when originally made with too little sugar. The want of due proportion of saccharine matter frequently also gives rise to mouldiness, when air has access to the syrup. It is said that syrups enclosed while they are still hot in bottles which are not full are apt to ferment, because the aqueous vapor rising to the surface and there condensing diminishes the proportion of sugar, so as to produce a commencement of chemical action, which grad-

ually extends through the whole mass, but if the bottles are filled, or are well shaken after they are cold, this result is obviated, and the syrups will generally keep better. When syrups undergo the vinous fermentation, they become covered at the surface with froth, produced by the disengagement of carbon dioxide, and acquire a vinous odor from the presence of alcohol, while their consistence is diminished by the loss of a portion of the sugar, which has been converted into that liquid. When the quantity of alcohol has increased to a certain point, the fermentation ceases, or goes on more slowly, owing to the preservative influence of that principle, and, as the active ingredient of the syrup has frequently undergone a material change, the preparation is sometimes heated to boiling, so as to drive off the alcohol and carbon dioxide and concentrate the liquid sufficiently. A syrup thus revived is never equal to a preparation which has not met with such a mishap, and it is far better to throw a fermented syrup away. It is obvious that syrups which depend for their virtues upon a volatile ingredient, or one which is readily changeable by heat, cannot be restored to their original condition.

A convenient method of preparing syrups has come into general use, called the "cold process." For some syrups it is to be preferred to the usual method of heating, and all syrups which contain a volatile principle, or one likely to be injured by heat, are preferably made by *percolation*. L. Orynski, *D. C.*, March, 1871, first drew attention to the subject, and R. Hunstock, in *A. J. P.*, Sept. 1875, and Sept. 1878, gave the results of his experience with the process. Into the lower orifice of a percolator he introduces lightly a small piece of sponge, which should be cleaned and thoroughly moistened with pure water, but any excess should be carefully pressed out before inserting it. The sugar (granulated) is then poured in, and upon this, the water, the apparatus being arranged as is usual in the process of percolation. The percolator may be covered loosely, and the operation will proceed without further attention, the syrup coming through drop by drop. If it should be necessary to use crushed sugar, the percolator must be corked at the lower orifice, and the sugar and water introduced and allowed to macerate until the former has dissolved down to *half its bulk*, when the cork may be removed and the liquid be allowed to drop. If, after the liquid has all passed, there remains a quantity of undissolved sugar in the percolator, after corking the end of the latter, enough percolate may be poured back to dissolve it, afterwards adding sufficient water to bring the whole up to the required measure. See *Am. Drug.*, July, 1903, 31. For official directions for preparing syrup by percolation see *Syrupus*, page 1217. The U. S. P. (8th Rev.) directs that a pledget of purified cotton should be used in place of the sponge; we have found by experience that some care is

necessary in adjusting the pledget, but after a little practice the pledget will be preferred to the sponge.

To be successful in using the process, care in several particulars must be exercised. 1. The percolator should be cylindrical or semi-cylindrical, and cone-shaped as it nears the lower orifice. 2. The sugar must be coarse, else it will form into a compact mass, which the liquid cannot permeate. 3. The sponge or pledget must be introduced with care. If pressed too tightly in, it will effectually stop the process; if inserted too loosely, the liquid will pass too rapidly, and will, in consequence, be weak and turbid (not properly filtered). See also a practical paper on this subject in *A. J. P.*, Jan. 1881, by G. H. Chas. Klie, and *Bull. Pharm.*, 1902, 1248. For a paper on *Fruit Syrups* see *West. Drug.*, 1902, 182; *Proc. Penn. Pharm. Assoc.*, 1903, 196.

Syrups may be made (without heat) *rapidly* by putting the ingredients in a churn and agitating briskly.

"Rock Candy Syrup," the evaporated mother liquor left after crystallizing sugar in the form of large crystals, called "rock candy," has come largely into use in America. It varies much in quality as made by various manufacturers, and often contains glucose. It should never be used indiscriminately or for making the official syrups, and it should always be carefully tested before being used for any purpose. (See analyses by L. F. Kebler, in *A. J. P.*, 1895, 143.)

At best, syrups are apt to change, and various measures have been proposed for their preservation, but the best plan is to make small quantities of syrups at a time, and to keep them, unless when wanted for immediate use, in bottles quite full and well stoppered, which should be put in the cellar or other cool place. Glycerin is often used to aid in the preservation of syrups; in special cases this may be advantageous, but the solvent properties of glycerin must be remembered, and the finished preparation may possess properties (due to the glycerin) which are not found in syrups made without glycerin, and which may therefore be injurious in prescriptions (see *West. Drug.*, 1898, 444).

The following Syrups were dropped from the U. S. Pharmacopœia 8th revision: *Syrupus Allii*, *Syrupus Althææ*, *Syrupus Hypophosphitum cum Ferro* and *Syrupus Rubi Idæi*, and from the British Pharmacopœia (1898), *Syrupus Ferri Subchloridi*, *Syrupus Mori*, and *Syrupus Papaveris*.

SYRUP

(sy-râ'pūs)

Syrupus Simplex; Simple Syrup; *Syrupus Sacchari* s. *Albus*; Sirop de Sucre, *Fr. Cod.*; Sirop simple, *Fr.*; *Syrupus simplex*, *P. G.*; Weisses Syrup, *G.*; Sciroppo semplice, *It.*; Jarabe simple, *Sp.*

* "Sugar, in dry crystalline granules, *eight hundred and fifty grammes* [or 29 ounces av., 430 grains]; Distilled Water, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Dissolve the Sugar, with the aid of heat, in *four hundred and fifty cubic centimeters* [or 15 fluidounces, 104 minims] of Distilled Water, raise the temperature to the boiling point, strain the liquid, and pass enough Distilled Water through the strainer to make the product, when cold, measure *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Mix thoroughly. Syrup may also be prepared in the following manner:

Press down into the neck of a percolator of suitable size a pledget of purified cotton, not too tightly, in such a manner that the cotton shall nearly fill the neck of the percolator, and moisten it with a few drops of Distilled Water; introduce the Sugar into the percolator, make its surface level without shaking or jarring, then carefully pour upon it *four hundred and fifty cubic centimeters* [or 15 fluidounces, 104 minims] of Distilled Water, and regulate the flow of the liquid, if necessary, so that it will pass out in rapid drops. Return the first portions of the percolate until it runs through clear, and when all the liquid has passed, follow it by Distilled Water, added in portions, so that all the Sugar may be dissolved, and the product measure *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Mix thoroughly." *U. S.*

"Refined Sugar, *5 pounds* (Imperial) or 1000 grammes; Distilled Water, boiling, a *sufficient quantity*. Add the Refined Sugar to *two pints* (Imp. meas.) or five hundred cubic centimetres of the boiling Distilled Water; heat until dissolved; make the weight of the product *seven pounds and a half* (Imp.) or one thousand five hundred grammes by the addition of boiling Distilled Water. Specific gravity 1.330." *Br.*

This syrup, when properly prepared, is inodorous, of a sweet taste without peculiar flavor, thick, viscid, nearly colorless, and perfectly transparent. If somewhat turbid, as it is apt to be when made with sugar not well refined, it may be clarified by beating the white of an egg to a froth with three or four ounces of water, mixing this with the syrup, boiling the mixture for a short time that the albumin may coagulate, and taking off the scum which rises to the surface, or separating it by filtration through paper or flannel. Two gallons of the syrup may be thus clarified. Any color and peculiar flavor which it may possess may be removed by treating it at the same time with a small proportion (about 5 per cent.) of animal charcoal.

The white of egg is beaten to a froth in order that when it coagulates it may be rendered by the air which it contains, specifically lighter than the syrup, and thus rise to the surface. If not thus treated it floats, when

coagulated, in the syrup, or sinks to the bottom. Now, it is obvious that if the syrup and albumin be heated together the latter must be deprived of a portion of the air which it contains before the point of coagulation is attained, and thus become less disposed to rise to the surface. Guibourt, therefore, recommends that it should not be added till the syrup is boiling hot, and should then be poured in from a height, in order to increase the quantity of air entangled in it. Magnes-Lahens has found paper pulp to be of the greatest service in the clarification of syrup. He uses a white unsized paper of good quality, reducing it to a paste by agitation in a bottle with a portion of the menstruum to be used, heating it with the syrup during the whole process of solution, and finally filtering through a "swan's-down paper" filter. (*P. J.*, April, 1872, p. 825.)

From the observations of Maumené, it appears that a solution of pure cane sugar, when long kept, undergoes a molecular change analogous to that produced by the reaction of weak acids, the saccharine liquid becoming brown when boiled with potassium hydroxide. But, as this phenomenon is exhibited alike by uncrystallizable sugar and by glucose, the experiment does not determine which of those forms of saccharine matter has been produced. (*C. R. A. S.*, xxxix. 914.) Procter observed a similar change in simple syrup which had been kept in his cabinet for six years. (*A. J. P.*, xxvii. 430.) Schaeuffele, having noticed, on one occasion, in the preparation of simple syrup, that the foam exhibited a singular blue color, while a part of the cane sugar was rapidly transformed into the uncrystallizable variety, made investigations as to the cause, and was led to the conclusion that it was the presence of indigo in the loaves of sugar, introduced with the view of giving brilliancy and whiteness, but this conclusion was probably erroneous, as it is well known that *ultramarine*, and not indigo, is used for this purpose. The presence of a blue coloring matter in sugar has frequently been noticed in this country; syrup made from such sugar is not colorless, and in a short time deposits a dark-colored sediment. Colorless "rock candy" forms an excellent source for pure syrup (the broken crystals can be procured cheaply from the manufacturers), and syrup entirely free from impurities is required in making such preparations as syrup of hydriodic acid, syrup of ferrous iodide, etc.

Syrup is very useful in the formation of pills and mixtures, and in various other pharmaceutical operations in which sugar in solution is required.

The U. S. syrup is practically identical with that formerly official, being a trifle stronger, the sp. gr. being given as 1.313 at 25° C. (77° F.). That of the Br. syrup is 1.330 at 15.5° C. (60° F.), probably adapted to the climate of Great Britain, which is not so cold in winter as is ours, at least in the Northern and Middle States.

It is also used as the vehicle for a number of official syrups.

SYRUPUS ACACIÆ. U. S.

SYRUP OF ACACIA

(sy-rá'pūs ā-cā'ci-æ)

Syrupus Gummosus; Sirop de Gomme, *Fr. Cod.*; Gummisirup, *G.*; Sciroppo di gomma arabica, *It.*; Jarabe de goma, *Sp.*

* "Acacia, in selected pieces, *one hundred grammes* [or 3 ounces av., 231 grains]; Sugar, *eight hundred grammes* [or 28 ounces av., 96 grains]; Distilled Water, *four hundred and thirty cubic centimeters* [or 14 fluidounces, 259 minims] to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Introduce the Acacia into an enamelled or porcelain dish, add the Distilled Water, and stir occasionally until the Acacia is dissolved; then, having added the Sugar, place the dish on a water-bath and apply heat, gradually increasing the temperature, and stirring from time to time until the Sugar is dissolved. Strain the Syrup, if necessary, and add sufficient Distilled Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].

Syrup of Acacia should be made in small quantities, and stored in small, tightly stoppered bottles, in a cool place." *U. S.* In the 18th edition of this work the process of the *U. S. P.* 1890¹ was condemned because of the tendency of the mucilage of acacia to spoil and thus make an unreliable syrup; the *U. S. P.* (8th Rev.) reintroduced the process of the *U. S. P.* 1870. This syrup is useful in the preparation of mixtures, pills, and troches, and is a good demulcent; but, unfortunately, the proportion of the gum to the sugar is too small to meet all the indications calling for the conjoint use of these substances. To avoid fermentation, C. B. Mann commends the use of one fluidounce of glycerin and seven fluidounces of water as the solvent. If the mucilage of acacia be made with chloroform water or a trace of chloroform be added to syrup of acacia, fermentation is measurably retarded.

¹ *Syrupus Acaciæ, U. S. 1890. Syrup of Acacia.* "Mucilage of Acacia, recently prepared, *twenty-five cubic centimeters* [or 46 minims]; Syrup, *seventy-five cubic centimeters* [or 2 fluidounces, 257 minims], to make *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]. Mix them. This syrup should be freshly prepared, when required." *U. S. 1890.*

SYRUPUS ACIDI CITRICI. U. S.

SYRUP OF CITRIC ACID

(sy-rá'pūs ā-cī'ī-dī cit'ri-cī)

Sirop d'Acide citrique, *Fr. Cod.*; Citronensauresirup, *G.*

* "Citric Acid, *ten grammes* [or 154 grains]; Distilled Water, *ten cubic centimeters* [or 162 minims]; Tincture of Fresh Lemon Peel, *ten cubic centimeters* [or 162 minims]; Syrup, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the Citric Acid in the Distilled Water, and mix the solution with *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Syrup. Then add the Tincture of Fresh Lemon Peel, and, lastly, enough Syrup to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." *U. S.*

This is more uniform in its character, keeps better, and is more readily prepared than lemon syrup, but does not equal it in flavor, if the latter be well made. If long kept it is prone to acquire a musty taste, and to deposit grape sugar copiously, in consequence of the action of the acid on the cane sugar. It is much employed as an agreeable and refrigerant addition to drinks, especially carbonic acid water. Tincture of fresh lemon peel is used in this syrup instead of spirit of lemon which was used in the process of the *U. S. P.* 1890; spirit of lemon is no longer official and the new tincture is preferable as a flavoring agent. Tartaric acid, on account of its greater cheapness, has not unfrequently been substituted for the citric acid; but the syrup made with it does not keep so well, and is more apt to be irritating to the stomach.

Off. Prep.—Liquor Magnesii Citratis, *U. S.*

SYRUPUS ACIDI HYDRIODICI. U. S.

SYRUP OF HYDRIODIC ACID

(sy-rá'pūs ā-cī'ī-dī hý-dri-ód'ī-cī)

"A syrupy liquid containing about 1 percent., by weight, of absolute Hydriodic Acid [HI = 126.9], or about 1.19 Gm. in 100 Cc." *U. S.*

Sirop d'Acide Iodhydrique, *Fr.*; Jodwasserstoff-sirup, *G.*

* "Diluted Hydriodic Acid, *one hundred grammes* [or 3 ounces av., 231 grains]; Water, *three hundred grammes* [or 10 ounces av., 255 grains]; Syrup, *six hundred grammes* [or 21 ounces av., 72 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Mix them." *U. S.*

An unprotected aqueous solution of hydriodic acid is unstable, the iodine being in time always liberated, rendering it irritant and unfit for internal administration, and as it has been proved that syrup protects the acid efficiently, the 1880

Committee of Revision introduced the Syrup of Hydriodic Acid, with the view of furnishing a preparation which should remain, if carefully preserved, for a long time unchanged. The process for this syrup was changed at the U. S. 1890 revision. The "Buchanan" method of producing hydriodic acid by the decomposition of potassium iodide with tartaric acid was employed, the resulting acid potassium tartrate being crystallized out by the use of diluted alcohol and a reduced temperature. Decomposition and the discoloration due to the separation of a trace of iodine were obviated by the use of a small quantity of potassium hypophosphite; this in contact with tartaric acid is decomposed, and the trace of hypophosphorous acid generated is sufficient to protect the solution of hydriodic acid from change, the very small quantity of acid potassium tartrate produced at the same time crystallizing out with the rest of the salt in the diluted alcohol. In the U. S. P. (8th Rev.) the syrup is made by adding to 1 part of diluted hydriodic acid 3 parts of water and 6 parts of syrup, it having been proved that diluted hydriodic acid could be made so as to be reasonably permanent (see *Acidum Hydriodicum Dilutum*, page 30), but the principal advantage is that the syrup can now be made extemporaneously as needed for prescriptions. Diluted syrup has been proved to make a more permanent syrup than syrup of official strength. So-called syrup of hydriodic acid is found in the market in which glycerin is the principal constituent. The substitution of glucose for syrup is also practised, the reason being given that the presence of glucose prevents discoloration. (*Proc. A. Ph.* A., 1897, 221.)

Properties.—Syrup of hydriodic acid is officially described as "a transparent, colorless, or not more than pale straw-colored liquid, odorless, and having a sweet and acidulous taste. Specific gravity: about 1.190 at 25° C. (77° F.). If a small portion of the Syrup be mixed with a little starch T.S., and a few drops of chlorine water then added, the liquid will acquire a deep blue color. Not more than a faint bluish tint should be produced in the Syrup by starch T.S. alone (limit of free iodine). The addition of silver nitrate T.S. to a small portion of the Syrup diluted with four volumes of water produces a pale yellow precipitate, nearly insoluble in ammonia water. If 31.73 (31.725) Gm. of Syrup of Hydriodic Acid be diluted with distilled water to measure 50 Cc., and if to 10 Cc. of this solution about an equal volume of distilled water, 8 Cc. of tenth-normal silver nitrate V.S., and 5 Cc. of diluted nitric acid be added, followed by 3 Cc. of ferric ammonium sulphate T.S., then, after thoroughly shaking the mixture, not more than 3 Cc. of tenth-normal potassium sulphocyanate V.S. should be required to produce a permanent reddish-brown tint (each Cc. of tenth-normal silver nitrate V.S. consumed corresponding to 0.2 percent. of absolute Hydriodic Acid)." U. S.

Syrup of hydriodic acid has the general therapeutic properties of iodine and the alkaline iodides, and is used by various practitioners to obtain alterative effects in *scrofula* and similar disorders. As it contains about 1 per cent. by weight of absolute hydriodic acid, for practical purposes a teaspoonful may be said to represent between 0.5 and 0.6 of a grain of iodine and a little over 1 grain of potassium iodide. It is evident that the doses in which it is usually administered—from twenty to forty minims (1.3 to 2.5 Cc.)—are too small. It should be well diluted at the time of administration, to prevent the possibility of injury to the teeth.

Dose, from one to two fluidrachms (3.75 to 7.5 Cc.).

SYRUPUS AMYGDALÆ. U. S.

SYRUP OF ALMOND

(sy-ră'pūs a-mŷg'da-læ)

Orgeat syrup; Syrupus Emulsivus; Sirop d'Amande, *Fr.* Od.; Sirop d'Orgeat, *Fr.*; Sirupus Amygdalarum, *P. G.*; Mandelsirup, *G.*

* "Spirit of Bitter Almond, *ten cubic centimeters* [or 162 minims]; Orange Flower Water, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Syrup, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix them." U. S.

The process for this syrup was greatly simplified in the U. S. P. (8th Rev.); when made by the U. S. P. 1890 process,¹ it quickly spoiled; as the syrup is used solely as a vehicle and for its fine flavor, the new process will undoubtedly be found more practical, permanent and satisfactory. It is said to mask the odor of musk and asafetida, when mixed with them.² It may

¹ *Syrupus Amygdalæ. U. S. 1890. Syrup of Almond. Syrup of Orgeat.*—"Sweet Almond, *one hundred and forty grammes* [or 1 ounce av., 411 grains]; Bitter Almond, *forty grammes* [or 1 ounce av., 180 grains]; Sugar, *two hundred grammes* [or 7 ounces av., 24 grains]; Orange Flower Water, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Water, *one hundred and thirty cubic centimeters* [or 4 fluidounces, 190 minims]; Syrup, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Rub the Almonds, previously blanched, in a mortar with *one hundred grammes* [or 3 ounces av., 231 grains] of the Sugar and *thirty cubic centimeters* [or 1 fluidounce] of Water to a smooth paste. Mix this well with the Orange Flower Water and *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Syrup, and strain with strong expression. To the residue add *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Water, and express again. In the strained liquid dissolve the remainder of the Sugar, without heat, adding enough Syrup to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Keep the Syrup in well-stoppered, completely filled bottles, in a cool place." U. S.

² *Orgeat Powder.*—Enders, on account of the tendency of syrup of almond to spoil, prepares a powder by making an emulsion of twenty parts of sweet almonds with sufficient water, mixing it with seventy-two parts of sugar, rapidly evaporating with the steam bath and pulverizing the residue, and keeping it in well-corked bottles. To make one hundred parts of the syrup, sixty-eight parts of the powder are dissolved with heat in twenty-four parts of water, and five parts of orange flower water and three parts of bitter almond water are added. (*A. J. P.*, 1874, p. 362.)

be added to cough mixtures, or used as an agreeable vehicle for administering strong remedies.

Dose, one to two fluidrachms (3.75 to 7.5 Cc.).

SYRUPUS AROMATICUS. Br.

AROMATIC SYRUP

(sy-rû'pûs ār-q-măt'i-cûs)

Sirop Aromatique, *Fr.*; Aromatischer Sirup, *G.*

"Tincture of Orange, 5 *fl. ounces* (Imperial measure) or 250 cubic centimetres; Cinnamon Water, 5 *fl. ounces* (Imp. meas.) or 250 cubic centimetres; Syrup, 10 *fl. ounces* (Imp. meas.) or 500 cubic centimetres. Mix the Tincture of Orange and Cinnamon Water; shake the mixture with a little powdered talc; filter; add the Syrup." *Br.*

This preparation of the Br. Ph. 1898 is practically a simple elixir (see *Elixir Aromaticum*, p. 433); it has been introduced mainly as a vehicle or adjuvant.

SYRUPUS AURANTII. U. S., Br.

SYRUP OF ORANGE

(sy-rû'pûs au-răn'ti-i)

Syrup of Orange Peel; Sirop d'Écorce d'Orange amère, *Fr. Cod.*; Sirupus Aurantii Corticis, *P. G.*; Pomeranzenschalsyrup, Orangenschalsensyrup, *G.*; Sciroppo di arancio amaro, *It.*; Jarabe de corteza de naranja amarga, *Sp.*

* "Tincture of Sweet Orange Peel, fifty cubic centimeters [or 1 fluidounce, 331 minims]; Citric Acid, five grammes [or 77 grains]; Magnesium Carbonate, ten grammes [or 154 grains]; Sugar, eight hundred and twenty grammes [or 28 ounces av., 405 grains]; Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Triturate the Magnesium Carbonate in a mortar with the Tincture, add gradually four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Water, filter, and add sufficient Water through the filter to obtain four hundred and fifty cubic centimeters [or 15 fluidounces, 104 minims] of filtrate; in this dissolve the Citric Acid and Sugar by agitation without heat, and add sufficient Water to make the product measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." *U. S.*

"Tincture of Orange, 1 *fl. ounce* (Imperial measure) or 30 cubic centimetres; Syrup, 7 *fl. ounces* (Imp. meas.) or 210 cubic centimetres. Mix." *Br.*

This process was changed in the U. S. P. (8th Rev.) the official 50 per cent. tincture being used in connection with magnesium carbonate, instead of making an alcoholic extract of fresh orange peel by boiling and using precipitated calcium phosphate as directed in the U. S. P. 1890.

The present U. S. formula is an improvement over that of 1870, in which evaporation was resorted to so as to deprive the tincture of orange peel of alcohol, for, although the temperature was limited to 120° F., even this was sufficient

to affect the flavor of the concentrated tincture. In the U. S. P. 1880, by employing maceration and expression with a smaller quantity of alcohol, the use of heat was avoided. The proportion of alcohol directed to extract the oil from the orange peel was necessarily small; indeed, it was almost entirely absorbed by the orange peel, which should be grated. In the U. S. P. 1890 process an attempt was made to economize time by boiling the sweet orange peel in alcohol. The British preparation, which is a mere mixture of the tincture with syrup, is inferior. The use of magnesium carbonate was first suggested by John D. Finley. The syrup has an agreeable flavor, for which it is alone employed. For a process by E. E. Williams, using powdered pumice to disintegrate the orange peel, see *D. C.*, 1898, 125.

SYRUPUS AURANTII FLORUM.

U. S. (Br.)

SYRUP OF ORANGE FLOWERS

(sy-rû'pûs au-răn'ti-i flô'rûm)

Syrupus Aurantii Floris, *Br.*; Sirop de Fleur d'Oranger, *Fr. Cod.*; Pomeranzenblüthensyrup, *G.*; Jarabe de azahar, *Sp.*

* "Sugar, eight hundred and fifty grammes [or 29 ounces av., 430 grains]; Orange Flower Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Dissolve the Sugar in four hundred and fifty cubic centimeters [or 15 fluidounces, 104 minims] of Orange Flower Water by agitation, without heat, add enough Orange Flower Water to make the product measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms], and mix thoroughly. Syrup of Orange Flowers may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under Syrupus. Pour four hundred and fifty cubic centimeters [or 15 fluidounces, 104 minims] of Orange Flower Water upon the Sugar, return the first portions of the percolate until it runs through clear, and, when all the liquid has passed, follow it by Orange Flower Water, until the product measures one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." *U. S.*

"Orange-flower water of commerce, undiluted, 8 *fl. ounces* (Imperial measure) or 100 cubic centimetres; Refined Sugar, 3 pounds (Imp.) or 600 grammes; Distilled Water, boiling, a sufficient quantity. Add the Refined Sugar to sixteen fluid ounces (Imp. meas.) or two hundred cubic centimetres of the boiling Distilled Water; heat until dissolved; add the undiluted orange-flower water; make the weight of the product four pounds and a half (Imp.) or nine hundred grammes by the addition of recently boiled Distilled Water." *Br.*

The second U. S. process, by percolation, will be preferable here. This syrup is used chiefly for flavoring mixtures.

Dose, a fluidrachm (3.75 Cc.).

SYRUPUS CALCII LACTOPHOSPHATIS.

U. S., Br.

SYRUP OF CALCIUM LACTOPHOSPHATE

(sy-rá'pūs cāl'cī-i lăc-to-phōs-phā'tis)

Sirop de Lactophosphate (phospholactate) de chaux, *Fr.*; Calciumphospholactatsirup, *G.*; Jarabe de lacto-fosfato calcico, *Sp.*

* "Precipitated Calcium Carbonate, *twenty-five grammes* [or 386 grains]; Lactic Acid, *sixty cubic centimeters* [or 2 fluidounces, 14 minims]; Phosphoric Acid, *thirty-six cubic centimeters* [or 1 fluidounce, 104 minims]; Orange Flower Water, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Sugar, *seven hundred and twenty-five grammes* [or 25 ounces av., 251 grains]; Water, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. To the Lactic Acid mixed with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Water, and contained in a capacious mortar, gradually add the Calcium Carbonate, in portions, stirring until it is dissolved. Then add the Phosphoric Acid, diluted with *fifty cubic centimeters* [or 1 fluidounce, 331 minims] of Water, and triturate until the precipitate at first formed is dissolved. Add *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Water, and filter, rinsing the mortar with *fifty cubic centimeters* [or 1 fluidounce, 331 minims] of Water, and passing the rinsings through the filter. To the mixed filtrates add the Orange Flower Water, and, having added the Sugar, dissolve it by agitation, without heat, and strain. Lastly, pass enough Water through the strainer to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms], and mix thoroughly." *U. S.*

"Precipitated Calcium Carbonate, 2½ ounces (Imperial) or 25 grammes; Concentrated Phosphoric Acid, 4 fl. ounces and 262 minims (Imp. meas.) or 46 cubic centimetres; Lactic Acid, 6 fl. ounces (Imp. meas.) or 60 cubic centimetres; Refined Sugar, 70 ounces (Imp.) or 700 grammes; Orange-flower water of commerce, undiluted, 2½ fl. ounces (Imp. meas.) or 25 cubic centimetres; Distilled Water, *a sufficient quantity*. Add the Calcium Carbonate gradually to the Lactic Acid, diluted with four times its volume of Distilled Water. When solution is complete, add the Concentrated Phosphoric Acid, and triturate until the precipitate which at first forms is dissolved. Dilute with a little Distilled Water; add the undiluted orange-flower water; filter; dissolve the Refined Sugar in the mixture without the aid of heat; strain; add sufficient Distilled Water to make *five pints* (Imp. meas.) or *one thousand cubic centimetres* of the syrup." *Br.*

The U. S. P. 1880 syrup was almost identical with the preparation proposed by William Neergaard. Freshly precipitated calcium phosphate is soluble in lactic acid, and this preparation was such a solution protected from change

and rendered more agreeable to the taste by the addition of sugar and orange flower water. As made by this formula it will usually be found to contain a precipitate of a gelatinous character, which gradually forms in the course of a few days or weeks; the means commonly used to prevent this precipitation is the addition of a fluidrachm of hydrochloric acid to a pint of the syrup,—hydrochloric acid being a better solvent for calcium phosphate than is lactic acid. The U. S. P. 1890 process¹ as well as that of the 8th Revision, prepared calcium lactate by dissolving calcium carbonate in lactic acid and subsequently adding phosphoric acid; this should be an improvement, as it simplifies the process. Precipitation can be avoided by the addition of a trace of hydrochloric acid. The process of percolation to dissolve the sugar may be advantageously substituted here for that of agitation. The syrup is sometimes prepared by dissolving two hundred grains of calcium lactophosphate (which is now furnished by the manufacturing chemists) in a pint of syrup flavored with orange flower water, a fluidrachm of hydrochloric acid being added to prevent precipitation. The British syrup is practically identical with the U. S. preparation and was modelled after it. The syrup affords an excellent means of administering calcium phosphate.

Dose, from two to four fluidrachms (7.5 to 15 Cc.), representing from three to six grains of the lime salt.

SYRUPUS CALCIS. U. S. (Br.)

SYRUP OF LIME SYRUP OF CALCIUM HYDROXIDE

(sy-rá'pūs cāl'cīs)

Liquor Calcis Saccharatus, *Br.*; Saccharated Solution of Lime; Syrupus Calcarii; Syrup of Calcium Hydroxide; Sirop de Chaux, *Fr.*; Kalksyrup, *G.*

* "Lime, *sixty-five grammes* [or 2 ounces av., 128 grains]; Sugar, *three hundred and fifty grammes* [or 12 ounces av., 151 grains]; Water, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Slake the Lime by the addition of *thirty-five cubic centimeters* [or 1 fluidounce, 88 minims] of Water with the aid of heat, then mix it and the Sugar thoroughly in a mortar, so as to form a homogeneous powder; add the mixture to *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of boiling Water, contained in a bright copper or tinned-iron vessel, and boil for five minutes, constantly stirring.

¹ *Syrupus Calcii Lactophosphatis. Modified Formula.*—Geo. Thos. Williams has modified the formula of R. Rother and adapted it to the strength of the official preparation. It is as follows: "Take of Precipitated Calcium Carbonate 13 parts; Lactic Acid 33 parts; Phosphoric Acid, U. S. P., 18 parts; Orange Flower Water 80 parts; Sugar in coarse powder 600 parts; Distilled Water sufficient to make 1000 parts. Mix the lactic acid with 136 parts of distilled water, and gradually add the calcium carbonate, warming gently, if necessary. Add the phosphoric acid, previously diluted with 120 parts of distilled water and with the orange flower water. Filter, and pass enough distilled water through the filter to make the filtrate weigh 400 parts. Lastly, dissolve the sugar by cold percolation or by agitation, and strain."

Dilute the liquid with sufficient Water to make it measure *nine hundred and fifty cubic centimeters* [or 32 fluidounces, 59 minims], and filter through white paper, closely covering the funnel during filtration. Then add through the filter enough Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms], and mix thoroughly. Keep the Syrup in well-stoppered bottles." *U. S.*

"Calcium Hydroxide, 1 ounce (Imperial) or 50 grammes; Refined Sugar, in powder, 2 ounces (Imp.) or 100 grammes; Distilled Water, 1 pint (Imp. meas.) or 1000 cubic centimetres. Mix the Calcium Hydroxide with a solution of the Refined Sugar in the Distilled Water. Set aside in a stoppered green glass bottle for a few hours, shaking occasionally; separate the clear Solution with a siphon, avoiding unnecessary exposure to air. Specific gravity 1.055. 10 grammes should require for neutralization 6.3 cubic centimetres of the volumetric solution of sulphuric acid. It should not afford any characteristic reaction with the tests for lead. This Solution contains nearly 2 per cent. by weight of Lime, CaO, or about 8 grains in 1 fluid ounce." *Br.* The quantity of sugar was reduced about 12 per cent. in the process of the U. S. P. 1890 as it was found by experiment that a syrup thus made was more permanent and less liable to become discolored.

Properties.—Syrup of Lime is officially described as a "transparent, pale yellow liquid, of alkaline taste and reaction. Specific gravity: about 1.145 at 25° C. (77° F.). The addition of a solution of an alkali carbonate produces a white precipitate, soluble in acids with effervescence. The addition of ammonium oxalate T.S. produces a white precipitate, insoluble in acetic acid, but soluble in hydrochloric acid." *U. S.*

The British saccharated solution of lime differs from the U. S. syrup in containing a smaller proportion of sugar and of lime. The official syrup is almost identical with that proposed by E. R. Squibb. (See 14th ed., U. S. D., p. 1288; also *Apoth.*, 1894, 18.)

Sugar forms with lime certain definite compounds which may be looked upon as sucra-tes. According to M. S. Benedikt (*J. P. C.*, 4e sér., xix, 96), there are at least four of these combinations. Some, if not all, of them are much more soluble than the lime itself, so that in this way a much stronger solution of lime can be obtained than by the instrumentality of water alone. The syrup remains perfectly transparent, and is in no degree disturbed by dilution with water. It has a decidedly alkaline and even caustic taste, and should always be largely diluted when administered. It was first prepared by M. Beral, and its practical use was originally suggested by Capitaine of Paris.¹

¹ *Liquid Glue.*—It is stated that a very adhesive glue, remaining liquid at ordinary temperatures, may be prepared by dissolving glue in a solution of sucra-tes of lime. (*A. J. P.*, 1872, 562.)

Uses.—Syrup of lime is an active antacid and astringent, which may be used as a substitute for lime water in all cases to which that preparation is suitable. 20 minims of it (1.25 Cc.) are equal to a fluidounce of lime water.

Dose, ten to thirty minims (0.6 to 1.8 Cc.).

SYRUPUS CASCARÆ AROMATICUS.

Br.

AROMATIC SYRUP OF CASCARA

(sy-rû'pûs câs'câ-ræ âr-q-mât'î-cûs)

Sirop aromatique de Cascara Sagrada, *Fr.*; Aromatischer Amerikanisch-Faulbaumrindensirup, *G.*

"Liquid Extract of Cascara Sagrada, 8 fl. ounces (Imperial measure) or 400 cubic centimetres; Tincture of Orange, 2 fl. ounces (Imp. meas.) or 100 cubic centimetres; Alcohol (90 per cent.), 1 fl. ounce (Imp. meas.) or 50 cubic centimetres; Cinnamon Water, 3 fl. ounces (Imp. meas.) or 150 cubic centimetres; Syrup, 6 fl. ounces (Imp. meas.) or 300 cubic centimetres. Mix." *Br.*

This was a new syrup in the *Br. Pharm.* 1898. It forms a convenient means of administering cascara, the alcohol being added to aid its preservation.

Dose, from one-half to two fluidrachms (1.8 to 7.5 Cc.).

SYRUPUS CHLORAL. *Br.*

SYRUP OF CHLORAL

(sy-rû'pûs çhlô'râl)

Sirop de Chloral, *Fr. Cod.*; Chloralhydratsirup, *G.*; Jarabe de hidrato de cloral, *Sp.*

"Chloral Hydrate, 1600 grains or 91.43 grammes; Distilled Water, 30 fl. drachms (Imperial measure) or 93.75 cubic centimetres; Syrup, a sufficient quantity. Dissolve the Chloral Hydrate in the Distilled Water; add the Syrup until the mixed product measures *one pint* (Imp. meas.) or five hundred cubic centimetres. 1 fluid drachm of this syrup contains 10 grains of Chloral Hydrate." *Br.*

Dose, two fluidrachms (7.5 Cc.), representing twenty grains of chloral.

SYRUPUS CODEINÆ. *Br.*

SYRUP OF CODEINE

(sy-rû'pûs cō-dē-ī'næ)

Sirop de Codéine, *Fr. Cod.*; Kodeinsirup, *G.*; Sciroppo di codeina, *It.*; Jarabe de codeína, *Sp.*

"Codeine Phosphate, 40 grains or 4.57 grammes; Distilled Water, ¼ fl. ounce (Imperial measure) or 12.5 cubic centimetres; Syrup, 19¼ fl. ounces (Imp. meas.) or 987.5 cubic centimetres. Dissolve the Codeine Phosphate in the Distilled Water; add the Syrup; mix. 1 fluid drachm of this Syrup contains ¼ grain of Codeine Phosphate." *Br.*

This syrup of the Br. Pharm. 1898 is intended to furnish a convenient method of using codeine phosphate.

Dose, one-half to two fluidrachms (1.8 to 7.5 Cc.).

SYRUPUS FERRI IODIDI. U. S., Br.

SYRUP OF FERROUS IODIDE

(sy-rû'pûs fêr'ri i-ôd'i-di)

"A syrupy liquid containing about 5 percent., by weight, of Ferrous Iodide [$\text{FeI}_2 = 307.30$], or about 6.74 Gm. in 100 Cc." U. S.

Syrup of Iodide of Iron; *Sirup d'Iodure de Fer*, *Fr. Cod.*; *Syrupus Ferri Iodati*, *P. G.*; *Elsenjodürsyrup*, *G.*; *Sciroppo di protoioduro di ferro*, *It.*; *Jarabe de yoduro ferroso*, *Sp.*

* "Iron, in the form of fine, bright wire, and cut into small pieces, *twelve and one-half grammes* [or 193 grains]; Iodine, *forty-one and one-half grammes* [or 1 ounce av., 203 grains]; Diluted Hypophosphorous Acid, *twenty cubic centimeters* [or 325 minims]; Sugar, *six hundred grammes* [or 21 ounces av., 72 grains]; Distilled Water, a sufficient quantity, to make *one thousand grammes* [or 35 ounces av., 120 grains]. Introduce the Iron into a flask of thin glass, having a capacity of about *five hundred cubic centimeters* [or 1 pint], add to it *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims] of Distilled Water, and afterwards the Iodine. Shake the mixture occasionally, checking the reaction, if necessary, by the affusion of cold water, and, when the solution has acquired a greenish color, and has lost the odor of Iodine, heat it to boiling and add at once *fifty grammes* [or 1 ounce av., 334 grains] of the Sugar; when this has dissolved, filter the solution into the remainder of the Sugar contained in a porcelain dish. Rinse the flask and Iron Wire with *one hundred and twenty-five cubic centimeters* [or 4 fluidounces, 109 minims] of Distilled Water and pass the washings through the filter into the Sugar. Stir the mixture with a porcelain or wooden spatula, heating the liquid on a water-bath until complete solution is effected, and, having passed the syrup through a clean muslin strainer into a tared bottle, add the Diluted Hypophosphorous Acid, and sufficient Distilled Water to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains]." U. S.

"Iron, in wire, $\frac{1}{2}$ ounce (Imperial) or 25 grammes; Iodine, 726 grains or 83 grammes; Refined Sugar, $16\frac{1}{2}$ ounces (Imp.) or 825 grammes; Distilled Water, a sufficient quantity. Add the Refined Sugar to *six fluid ounces* (Imp. meas.) or three hundred cubic centimetres of boiling Distilled Water and heat until dissolved. Dilute *half a fluid ounce* (Imp. meas.) or twenty-five cubic centimetres of the resulting syrup with an equal volume of Distilled Water and set aside. Digest the Iodine and the Iron wire in a flask with *two and a half fluid ounces* (Imp. meas.) or one hundred

and twenty-five cubic centimetres of Distilled Water; heat gently, and finally boil slightly, until the froth loses its yellow color; filter the liquid while still hot into the syrup, washing the flask and the filter with the diluted syrup previously set aside and now heated to boiling. Pass sufficient boiling Distilled Water through the filter to produce, when cold, *one pint* (Imp. meas.) or one thousand cubic centimetres. Mix. The Syrup should have a specific gravity of 1.380 to 1.387. 11 minims of this Syrup contain 1 grain of ferrous iodide." Br.

These preparations furnish solutions of ferrous iodide rendered more permanent by sugar. The iodine should be dry, for, if moist, as commercial iodine often is, less ferrous iodide will be formed and the syrup will be proportionally weaker. In both processes a large excess of iron is taken, although the excess was reduced in the Br. Pharm. 1898. A moderate excess is useful in preventing the solution of ferrous iodide from undergoing any change from the absorption of oxygen during filtration, before it comes in contact with the sugar. The method adopted in the Pharmacopœia of 1880, of filtering the unprotected solution of ferrous iodide into the sugar contained in an open porcelain dish, and afterward straining the syrup through linen, was directly opposed to the experience of many practical pharmacists, and to the views which had been hitherto held of the action of the air upon the solution of ferrous iodide, and although with care, in skillful hands, oxidation may have been avoided, nothing was gained in time. In the U. S. P. (8th Rev.) process a small quantity of sugar is added to the solution of ferrous iodide before filtering, but the principle change was in the reduction of the strength of the finished syrup to 5 per cent. of ferrous iodide, which is *one half the quantity of ferrous iodide* that was in the former official syrup (10 per cent.). The strength of 5 per cent. is that recommended by the Brussels International Conference for the unification of the formulas for Potent Remedies. The process of the Pharmacopœia of 1890 was practically identical with the U. S. 1870 process. An improvement in this, however, would be to heat the syrup to boiling immediately before filtering the solution of ferrous iodide into it. Assuming that the iodine without loss is all converted into ferrous iodide, it is easy to calculate the strength of the official solutions. Thus, it will be found that the U. S. syrup contains about 3.84 grains, and that of the British Pharmacopœia 5.45 grains, of the dry iodide to the fluidrachm. In both preparations there is sufficient sugar to constitute a syrup,—the present U. S. process differing in this respect from that of 1850, which was denominated a solution, because containing insufficient sugar to be entitled to the name of a syrup. Indeed, the proportion of sugar in the old formula was insufficient duly to protect the iodide, and was therefore increased. In the solution of 1850, a coil of iron

wire, or a strip of bright iron, immersed in the solution, was found to assist in preserving it. Rock candy (pure crystallized sugar) has been frequently proposed as a substitute for commercial white sugar in making this syrup; there is no doubt that it is much to be preferred.

The plan of protecting the solution of ferrous iodide from change by saccharine matter originated with M. Frederking of Riga, who published a formula for the purpose in *Buchner's Repertorium* in 1839. The same plan was proposed in a paper by Procter, contained in the *A. J. P.* for April, 1840. In the *J. P. C.* for March, 1841, Dupasquier of Lyons, claims to have made a pure ferrous iodide protected by syrup of gum, as early as 1838. In the *P. J.* for August, 1841, the late A. T. Thomson published a paper in which he confirmed the results of Frederking and Procter, and proposed a formula for a *strong syrup*, which is the basis of that adopted by the British Pharmacopœia. For a practical process for making this syrup on a large scale, see *N. R.*, March, 1880.

Properties.—The U. S. syrup of ferrous iodide is "a transparent, pale green liquid, having a sweet, strongly ferruginous taste and an acid reaction. Specific gravity: about 1.349 at 25° C. (77° F.). On adding a few drops of potassium ferricyanide T.S. to a small portion of the diluted Syrup a blue precipitate will be produced. If mixed with a little starch T.S., and afterwards with a few drops of chlorine water, the syrup will acquire a deep blue color. This color should not be produced in the Syrup by starch T.S. alone (absence of *free iodine*). If 10 Gm. of Syrup of Ferrous Iodide be diluted with distilled water to measure 100 Cc., and 15.4 (15.36) Cc. of the solution be mixed with 15 Cc. of water, 6 Cc. of tenth-normal silver nitrate V.S., and 2 Cc. each of diluted nitric acid and ferric ammonium sulphate T.S., then, after thoroughly shaking the mixture, not more than 1 Cc. of tenth-normal potassium sulphocyanate V.S. should be required to produce a permanent reddish-brown tint (each Cc. of tenth-normal silver nitrate V.S. consumed corresponding to 1 percent. of Ferrous Iodide)." *U. S.* "Dissolve 1 gramme of dried sodium carbonate in 10 cubic centimetres of water, in a flask of which the capacity to a mark on the neck is 100 cubic centimetres; pour into the flask 10 cubic centimetres (or 13.87 grammes) of the Syrup, and agitate the mixture occasionally until the precipitation of the iron is complete; then add more water to make the whole measure 100 cubic centimetres; mix and filter. 25 cubic centimetres of the filtrate, neutralized with diluted nitric acid, should require not less than 16 and not more than 16.5 cubic centimetres of the volumetric solution of silver nitrate for complete precipitation of the iodine, solution of potassium chromate being used as an indicator." *Br.* In regard to the former U. S. syrup, E.

S. Wayne observed that, when kept for some time, it occasionally deposited grape sugar, into which the cane sugar was converted probably through the agency of hydriodic acid. According to J. M. Maisch, the solution was decomposed not only by light, but also by the action of atmospheric oxygen in bottles partly filled and frequently opened. The oxidation of the iron and the evolution of the iodine were accelerated by the action of light, when the solution was thus insecurely kept; but when the altered solution was transferred to air-tight bottles completely filled, and exposed to the direct light of the sun, it resumed its transparency, and its original tint was restored, or its color rendered much lighter. After this restoration the solution could not be the same, and it is probable that it contained some ferric iodate. The removal of the apparent defects of a solution of ferrous iodide by the action of sunlight is, therefore, not an admissible expedient, because it changes the nature of the solution. The same may be said of the addition of tartaric or citric acid, which has been proposed for clearing the discolored syrup. Syrup of ferrous iodide is rendered brown by sulphuric acid, and emits violet vapors when heated.

Squibb stated, in a communication to the *A. J. P.* (March, 1868, p. 99), that, after considerable experience with the U. S. 1860 syrup, he has known it to become discolored in only one instance; so that with care to avoid all injurious exposure it may be expected to keep well. But, in consequence of the facility with which it undergoes decomposition, with the liberation of iodine, it is very liable to become discolored with the least want of care. He therefore proposed, as a remedy for this inconvenience, to add to the discolored syrup a very small proportion of a solution of sodium thiosulphate, which, without injury to the preparation, removes the color and in a great degree restores the transparency. For this purpose fifteen or twenty grains of the crystallized thiosulphate may be dissolved in a fluidounce of water, and from fifteen to twenty minims of the solution are sufficient for a pint of syrup, if not darker than brown sherry. The solution is simply added to the syrup, and shaken up with it in the bottle. If the discoloration be deeper, more will be required, and the quantity requisite for the effect is a measure of the amount of change that may have occurred. The objection to the use of this salt is that a precipitate of sulphur usually takes place which is so fine that it is very difficult to separate. Syrup of ferrous iodide will on long keeping become permanently discolored through the action of hydriodic acid on the sugar, which causes caramelization, an effect frequently observed in syrups containing citric, tartaric, or other acids. This discoloration must not be confounded with that due to the liberation of iodine. J. F. Judge (*A. J. P.*, 1876, p. 159) recommended hypophosphorous acid in

small proportions to restore the pale green color, and of all the additions that have been proposed this is unquestionably the least objectionable and the most effective. (Y. B. P., 1885, p. 484.) Charles Rice preserved syrup of ferrous iodide successfully on the large scale by storing it in vessels having a stopcock at the bottom and pouring a small quantity of pure olive oil upon the surface to protect from oxidation. A. G. Hammer proposed the addition of syrup to a boiling solution of ferrous iodide before filtering from the excess of iron, and attributes the success in preservation to the fact that a portion of the cane sugar is converted into grape sugar which he believes has greater powers in preventing change. (Pharm., 1876, p. 99.) Glycerin has been proposed as a substitute for sugar in this preparation; it answers the same purpose, but it may be doubted whether more effectually. Glucose or solution of grape sugar has been repeatedly recommended as superior to ordinary syrup for use in this preparation; when the glucose is pure, it is superior as a preservative.

When the syrup is concentrated it becomes brown, and when evaporated to dryness forms a mass which may be called *saccharine ferrous iodide*, and which is not entirely soluble again, a little ferric oxide being left. This saccharine iodide, being protected by the sugar it contains, is not liable to the objections which apply to the pure solid salt (see *Ferrous Iodide*, PART II),¹ and may be made into pills, but this preparation is inferior to the *Ferri Iodidum Saccharatum* U. S. P. 1890.²

¹ *Tasteless Salts of Iron*.—A class of preparations of iron has been introduced by J. L. A. Creuse (A. J. P., xlv. 214). It has long been known that ammonium citrate has the property of rendering soluble many ordinarily insoluble preparations of iron. Creuse believes that all the salts of ferric oxide form chemical combinations with all the alkaline (ammonium, sodium, potassium, lithium) citrates, which combinations are all greenish, soluble in water, nearly insoluble in alcohol, free from ferruginous taste, perfectly stable, and so resist decomposition as to form no precipitate with cinchona bark; indeed, chemical reagents do not reveal the iron in them unless strong acids or hydrogen sulphide be used. None of these salts coagulate the blood; they cannot be used as styptics.

Tasteless Iron Iodide is prepared in the following manner: 426.3 grains of iodine are combined with iron in the usual way to obtain the solution of ferrous iodide; this is filtered and 63 grains of iodine dissolved in it; a solution of 201 grains of citric acid is saturated with potassium hydroxide and then added gradually to the first solution. When the apple-green color has been developed, the solution is evaporated, with gentle stirring, to dryness, when cauliflower-like masses of acicular crystals will be obtained. These are stable except in direct sunlight.

Tasteless Iron Chloride is made by adding an alkaline citrate in solution to a solution of iron sesquichloride, in such proportion that there shall be two molecules of the former to three molecules of chlorine. Usually from 120 to 140 grains of citric acid saturated with ammonia, sodium or potassium hydroxide are required for the preparation of an ounce of a tincture of corresponding strength to the official tincture. The addition should be made to the liquor, and the final solution must not contain more than 40 per cent. of alcohol. R. Rother affirmed that these so-called salts are mere mixtures of iron citrate and iodide or chloride of the alkali used. (A. J. P., 1876, p. 471.)

² *Ferri Iodidum Saccharatum*, U. S. 1890. *Saccharated Ferrous Iodide*.—"Iron, in the form of fine, bright wire, and cut into small pieces, *six grammes* [or 92 grains]; Reduced Iron, *one gramme* [or 15.5 grains]; Iodine, *seventeen grammes* [or 262 grains];

Liquor Ferri Iodidi, Solution of Ferrous Iodide.—Niece (M. R., 1903, 70) suggested the following process for this solution of ferrous iodide as a stock preparation from which the syrup of ferrous iodide is readily made by mixing 3 parts (by volume) with 26 parts (by volume) of syrup. Glycerin and diluted hypophosphorous acid are recommended as valuable additions for preserving the solution. The iron wire must be carefully cleaned from dust and grease by washing with a 2 per cent. aqueous solution of hydrochloric acid, then with distilled water, and rapidly drying, weighing out the desired quantity and introducing it into a clean, dry pint flask, together with 2 fl. ounces of distilled water. The proportions are as follows: Iron (clean, dry, bright card teeth), 330 grains; Iodine (resublimed and dry), 1120 grains; Hypophosphorous Acid (10 per cent.), 1 fl. drachm; Glycerin, previously warmed (sp. gr. 1.25), 1 fl. drachm; Water (dis-

tilled Water, Sugar of Milk, recently dried, each, a sufficient quantity, to make one hundred grammes [or 3 ounces av., 231 grains]. Mix the Iron Wire, Iodine, and twenty cubic centimeters [or 325 minims] of Distilled Water in a flask of thin glass, shake the mixture occasionally, until the reaction ceases, and the solution has acquired a green color and lost the smell of iodine; then filter it through a small, wetted filter into a porcelain capsule containing forty grammes [or 1 ounce av., 180 grains] of Sugar of Milk. Rinse the flask and Iron Wire with a little Distilled Water, pass the rinsings through the filter into the capsule, and evaporate, on a water-bath, with frequent stirring, until a dry mass remains. Transfer this quickly to a heated iron mortar, reduce it to powder, and mix it intimately, by trituration, with the Reduced Iron and enough Sugar of Milk to make the final product weigh one hundred grammes [or 3 ounces av., 231 grains]. Transfer the powder at once to small and perfectly dry bottles, which should be securely stoppered, and kept in a cool and dark place." U. S. 1890. This preparation is practically identical with the Saccharated Iodide of Iron of the German Pharmacopoeia, and consists of ferrous iodide preserved by contact with sugar of milk. It is a more stable form of administering ferrous iodide than the salt in its pure state. (See *Ferrous Iodide*.) The addition of reduced iron to the preparation just before the close of the process is for the purpose of protecting it from change; any iodine which may be set free through exposure will combine with the reduced iron, and thus the irritating effects of free iodine will be avoided.

Properties.—The U. S. P. 1890 gave the following description: "A yellowish-white or grayish, very hygroscopic powder, without odor, and having a sweetish, ferruginous taste. Soluble (with exception of the added reduced iron) in 7 parts of water at 15° C. (59° F.), but only partially soluble in alcohol. When strongly heated, the compound swells up, evolves the odor of iodine and of burning sugar, and on complete ignition, leaves a residue which should yield nothing soluble to water (absence of salts of the fixed alkalis). The aqueous solution has a slightly acid reaction, and gives with potassium ferricyanide test-solution a blue precipitate. If the aqueous solution be mixed with a little starch test-solution, and afterwards with a few drops of chlorine water, it will assume a deep blue color. This color should not be developed in the aqueous solution by starch test-solution alone (absence of free iodine). If 1.55 (1.5447) Gm. of Saccharated Ferrous Iodide be dissolved in about 20 Cc. of water, in a small flask, and to this solution be successively added, first, 22 Cc. of silver nitrate decinormal volumetric solution, then 5 Cc. of diluted nitric acid and 5 Cc. of ferric ammonium sulphate test-solution, it should not require more than 2 Cc. of potassium sulphocyanate decinormal volumetric solution to produce a reddish-brown tint which persists after shaking (corresponding to about 20 per cent. of pure Ferrous Iodide)." U. S. 1890.

Uses.—The medicinal properties of this preparation are identical with those of ferrous iodide. (See *Ferrous Iodide*, PART II.) The dose is from two to five grains (0.13 to 0.32 Gm.).

tilled and ammonia-free) to make 4 fl. ounces. The iodine is added in portions, one-fourth at a time, and the flask shaken after each addition until the red color disappears. After all has been thus added, the flask is heated and the contents boiled for two or three minutes—the liquid having previously assumed a greenish hue; it is then filtered, using a long-stemmed funnel, well-covered, and extending into the mixture of glycerin and hypophosphorous acid—the measure being brought to four fluidounces with the distilled water rinsings of the flask, passed through the same filter. The finished solution is preserved in one-ounce bottles of brown glass, completely filled, with the ground-glass stopper well paraffined, and stored in a cool, dark place. Well cleaned implements, entirely of glass where they come in direct contact with the solution, must be used invariably throughout the entire process.

Uses.—The syrup of ferrous iodide combines the alternative action of iodine with the hematinic action of iron. It is a popular remedy in chronic types of *tuberculosis*, especially in the *scrofula* of children. It has, however, no advantage over an extemporaneous combination of an iodide with ferruginous tonic, and has the drawback that the dose of either ingredient cannot be altered singly.

Dose, for an adult thirty to forty minims (1.8 to 2.5 Cc.); for a child of two years five to ten minims (0.3 to 0.6 Cc.).

SYRUPUS FERRI PHOSPHATIS. Br.

SYRUP OF FERROUS PHOSPHATE

(sy-rû'pûs fêr'ri phôs-phâ'tis)

Sirup de Phosphate de Fer, *Fr.*; Eisenphosphat-sirup, *G.*

"Iron, in wire, 75 grains or 8.6 grammes; Concentrated Phosphoric Acid, $1\frac{1}{2}$ fl. ounces (Imperial measure) or 62.5 cubic centimetres; Syrup, 14 fl. ounces (Imp. meas.) or 700 cubic centimetres; Distilled Water, a sufficient quantity. Place the Iron wire and the Concentrated Phosphoric Acid, previously diluted with an equal volume of Distilled Water, in a small flask; plug the neck with cotton wool, and heat gently until the Iron is dissolved. When cold, filter into the Syrup, and pass a sufficient quantity of Distilled Water through the filter to make the product measure one pint (Imp. meas.) or one thousand cubic centimetres. 1 fluid drachm of this Syrup represents 1 grain of anhydrous ferrous phosphate." *Br.*

The process for this syrup of the *Br. Pharmacopœia* has been greatly improved. H. W. Jones (*P. J.*, 3d ser., v. 541) proposed a formula in which the phosphate was made directly from metallic iron and phosphoric acid. R. Wright (*P. J.*, 1893, 191) improved the formula, and this method is superior to the cumbersome process of preparing a precipitate of ferric phosphate, and dissolving it in phosphoric acid. The syrup is a solution of ferrous

phosphate protected by sugar. The sp. gr. is about 1.270. (Umney.) For its properties and uses, see *Ferri Phosphas*, page 508.

Dose, from one to two fluidrachms (3.75 to 7.5 Cc.).

SYRUPUS FERRI, QUININÆ ET STRYCHNINÆ PHOSPHATUM. U. S. (Br.)

SYRUP OF THE PHOSPHATES OF IRON, QUININE, AND STRYCHNINE

(sy-rû'pûs fêr'ri qui-nî'næ êt strý'ch-nî'næ phôs-phâ'tum)

Syrupus Ferri Phosphatis cum Quinina et Strychnina. *Br.*; Syrup of Phosphate of Iron with Quinine and Strychnine; Easton's Syrup; Sirup Tonique d'Easton, *Fr.*; Eisenphosphatsirup mit Chinin und Strychnin, Eastonscher Sirup, *G.*

* "Glycerite of the Phosphates of Iron, Quinine and Strychnine, two hundred and fifty cubic centimeters [or 8 fluidounces, 218 minims]; Syrup, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix them. Strain, if necessary." *U. S.*

"Iron, in wire, 75 grains or 8.6 grammes; Concentrated Phosphoric Acid, $1\frac{1}{2}$ fl. ounces (Imperial measure) or 62.5 cubic centimetres; Strychnine, in powder, 5 grains or 0.57 gramme; Quinine Sulphate, 130 grains or 14.8 grammes; Syrup, 14 fl. ounces (Imp. meas.) or 700 cubic centimetres; Distilled Water, a sufficient quantity. Place the Iron wire and the Concentrated Phosphoric Acid, previously diluted with an equal volume of Distilled Water, in a small flask; plug the neck with cotton wool, and heat gently until the Iron is dissolved; in the resulting solution dissolve the Strychnine and Quinine Sulphate; filter into the Syrup; pass sufficient Distilled Water through the filter to make the product measure one pint (Imp. meas.) or one thousand cubic centimetres. One fluid drachm of this Syrup represents 1 grain of anhydrous ferrous phosphate, four-fifths grain of Quinine Sulphate, and one-thirty-second grain of Strychnine." *Br.*

This preparation is now made by diluting the glycerite (see *Glyceritum Ferri, Quinina et Strychnina Phosphatum*) with syrup. Each fluidrachm of the syrup contains about one grain and one-seventh of ferric phosphate, one grain and one-half of quinine, and one eighty-seventh of a grain of strychnine. The *Br. Ph.* directs the preparation of a fresh solution of ferrous phosphate from iron wire and phosphoric acid, as suggested by Wright (*P. J.*, 1893, 19); it contains less quinine and strychnine and is more permanent than the *U. S.* syrup. Discoloration, due to light, is usually noticed in this syrup, and it has been repeatedly suggested that glucose be substituted for syrup to prevent this fault. The use of the glycerite as directed by the *U. S. P.* (8th Rev.) permits the extemporaneous preparation of the syrup, so that there can be no excuse

for dispensing a discolored syrup. An insoluble precipitate of basic ferric phosphate is likely to be produced when this syrup is kept.

Uses.—This syrup has the medicinal activities of its ingredients, but is a very ineligible preparation, and has not even an agreeable taste to excuse its polypharmacy. It is known as *Easton's Syrup*, *Aitkin's Syrup*, *Syrup of the Three Phosphates*, and *Syrup of Triple Phosphates*.

Dose, one to two fluidrachms (3.75 to 7.5 Ce.).

SYRUPUS GLUCOSI. Br.

SYRUP OF GLUCOSE

(sy-rá'pūs glŭ-cō'sī)

Sirop de Glycose, *Fr.*; Glykosesirup, *G.*

"Liquid Glucose, of commerce, 1 ounce (Imperial) or 25 grammes; Syrup, 2 ounces (Imp.) or 50 grammes. Mix, by the aid of gentle heat." *Br.*

This is a new preparation of the *Br. Ph.* 1898. It may be used as a vehicle for syrups which contain chemical salts liable to discoloration through the action of light, but its principal use is to take the place of treacle or molasses so much used in British pharmacy as a pill excipient. (See *Pilule*, p. 950.)

SYRUPUS HEMIDESMI. Br.

SYRUP OF HEMIDESMUS

(sy-rá'pūs hēm-ī-dēs'mī)

Syrup of Indian Sarsaparilla; Sirop de Hemidesmus, *Fr.*; Hemidesmussirup, *G.*

"Hemidesmus Root, bruised, 4 ounces (Imperial) or 100 grammes; Refined Sugar, 28 ounces (Imp.) or 700 grammes; Distilled Water, boiling, 1 pint (Imp. meas.) or 500 cubic centimetres. Infuse the Hemidesmus Root in the Distilled Water, in a covered vessel, for four hours, and strain. Set the infusion aside until clear; then decant the clear liquid, add the Refined Sugar, and dissolve by the aid of gentle heat. The weight of the product should be forty-two ounces (Imp.), or one thousand and fifty grammes." *Br.*

This is a very weak preparation. The *dose* is stated at one fluidrachm (3.75 Ce.); but the syrup may be taken almost *ad libitum*. (See *Hemidesmus*.)

SYRUPUS HYPOPHOSPHITUM. U. S.

SYRUP OF HYPOPHOSPHITES

(sy-rá'pūs hŷ-pō-phōs-phī'tūm)

Syrupus Calcii Hypophosphitis Compositus; Sirop d'Hypophosphite de Chaux composé, Sirop de Hypophosphites, *Fr.*; Hypophosphitsirup, *G.*

*"Calcium Hypophosphite, forty-five grammes [or 1 ounce av., 257 grains]; Potassium Hypophosphite, fifteen grammes [or 231 grains]; Sodium Hypophosphite, fifteen gram-

mes [or 231 grains]; Diluted Hypophosphorous Acid, two grammes [or 31 grains]; Sugar, six hundred and fifty grammes [or 22 ounces av., 406 grains]; Tincture of Fresh Lemon Peel, five cubic centimeters [or 81 minims]; Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Triturate the Hypophosphites with four hundred and fifty cubic centimeters [or 15 fluidounces, 104 minims] of Water, until they are dissolved, add the Tincture of Fresh Lemon Peel, and the Hypophosphorous Acid, and filter the liquid. In the filtrate dissolve the Sugar by agitation, without heat, and add enough water, through the filter, to make the product measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Strain, if necessary. Syrup of Hypophosphites may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under *Syrupus*. Pour the filtrate obtained as directed in the preceding formula upon the Sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it with Water, until the product measures one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." *U. S.*

This syrup is a simple solution of calcium, sodium, and potassium hypophosphites, in water, protected by sugar, and flavored with the tincture of fresh lemon peel. The calcium hypophosphite will usually not entirely dissolve; hence the direction to use hypophosphorous acid to complete the solution. Percolation will no doubt be preferred by many to agitation, for dissolving the sugar. It has been stated that the sulphuretted odor sometimes noticed in this syrup is due to the decomposition of sulphates or sulphites (present as impurities in the salts) by the hypophosphorous acid. (*P. J.*, 1895, 143.) Each fluidrachm of the syrup contains about two and a half grains of calcium hypophosphite, and not quite one grain each of the sodium and potassium salts. This syrup affords an excellent means of administering the hypophosphites.

Dose, from one to two fluidrachms (3.75 to 7.5 Ce.).

SYRUPUS HYPOPHOSPHITUM COMPOSITUS. U. S.

COMPOUND SYRUP OF HYPOPHOSPHITES

(sy-rá'pūs hŷ-pō-phōs-phī'tūm cōm-pōs'ī-tūs)

Sirop des Hypophosphites Composé, *Fr.*; Zusammengesetzter Hypophosphitsirup, *G.*

*"Calcium Hypophosphite, thirty-five grammes [or 1 ounce av., 103 grains]; Potassium Hypophosphite, seventeen and one-half grammes [or 270 grains]; Sodium Hypophosphite, seventeen and one-half grammes [or 270 grains]; Ferric Hypophosphite, two and one-fourth grammes [or 35 grains]; Manganese Hy-

pophosphite, two and one-fourth grammes [or 35 grains]; Quinine, one and one-tenth grammes [or 17 grains]; Strychnine, one hundred and fifteen milligrammes [or $1\frac{1}{2}$ grains]; Sodium Citrate, three and three-fourths grammes [or 58 grains]; Diluted Hypophosphorous Acid, fifteen cubic centimeters [or 243 minims]; Sugar, seven hundred and seventy-five grammes [or 27 ounces av., 147 grains]; Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Rub the Ferrie and Manganese Hypophosphites with the Sodium Citrate, add thirty cubic centimeters [or 1 fluidounce, 7 minims] of Water and warm the mixture for a few minutes, until a clear greenish solution is obtained. Dissolve the Calcium, Potassium, and Sodium Hypophosphites in four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Water, to which five cubic centimeters [or 81 minims] of Diluted Hypophosphorous Acid has previously been added; then dissolve the Quinine and Strychnine in thirty cubic centimeters [or 1 fluidounce, 7 minims] of Water with the aid of ten cubic centimeters [or 162 minims] of Diluted Hypophosphorous Acid, and finally dissolve the Sugar, with agitation, in these solutions, previously mixed. Strain the Syrup, if necessary, and add sufficient Water, through the strainer, to make the product measure one thousand cubic centimeters [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms].” U. S.

This syrup differs materially from the syrup of hypophosphites with iron official in the U. S. P. 1890;¹ it contains besides the hypophos-

phites of calcium, potassium, sodium and iron, the alkaloids quinine and strychnine, it is essentially the process of H. A. B. Dunning of Baltimore. Each fluidrachm contains 2 grains of calcium hypophosphite, 1 grain each of sodium and potassium hypophosphites, $\frac{1}{2}$ grain each of iron and manganese hypophosphites, 1-16 grain of quinine and 1-152 grain of strychnine.

Uses.—This syrup combines the alterative action of the hypophosphites with the hematinic properties of iron and is used in conditions of mild cachexia or scrofula.

Dose, one to two fluidrachms (3.7 to 7.5 Cc.).

SYRUPUS IPECACUANHÆ. U. S.

SYRUP OF IPECAC

(sy-rū'pūs ip-e-căo-ū-ăn'hæ)

Sirup d'Ipecacuanha. *Fr. Cod.*; Sirupus Ipecacuanhæ. *P. G.*; Brechwurzelsirup, Ipecacuanhasirup. *G.*; Sciroppo di Ipecacuanha, *It.*; Jarabe de Ipecacuanha, *Sp.*

* “Fluidextract of Ipecac, seventy cubic centimeters [or 2 fluidounces, 176 minims]; Acetic Acid, ten cubic centimeters [or 162 minims]; Glycerin, one hundred cubic centimeters [or 3 fluidounces, 183 minims]; Sugar, seven hundred grammes [or 24 ounces av., 303 grains]; Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Dilute the Fluidextract of Ipecac with three hundred cubic centimeters [or 10 fluidounces, 69 minims] of Water to which the Acetic Acid has previously been added, and mix them thoroughly by shaking; set the liquid aside in a cool place for twenty-four hours. Then filter, and pass enough Water through the filter to obtain four hundred and fifty cubic centimeters [or 15 fluidounces, 104 minims] of filtrate. To this liquid add the Glycerin, dissolve the Sugar in the mixture, and add enough Water to make the product measure one thousand cubic centimeters [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Mix thoroughly, and strain, if necessary. Syrup of Ipecac may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under *Syrupus*. Mix the filtrate obtained as directed in the preceding formula with the Glycerin, pour the mixture upon the Sugar, return the first portion of the percolate, until it runs through clear, and, when all the liquid has

¹ *Syrupus Hypophosphitum cum Ferro*. U. S. 1890. *Syrup of Hypophosphites with Iron.*—“Ferrous Lactate, ten grammes [or 154 grains]; Potassium Citrate, ten grammes [or 154 grains]; Syrup of Hypophosphites, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Rub the Ferrous Lactate and Potassium Citrate with a small quantity of the Syrup, gradually added, until they are dissolved. Then strain, and add enough Syrup of Hypophosphites to make the product measure one thousand cubic centimeters [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Mix thoroughly. This preparation should be freshly made when wanted.” U. S. 1890.

This syrup, which was made official in the U. S. P. 1880 for the first time, has been the subject of considerable pharmaceutical discussion because of the difficulty of selecting a salt of iron which would remain in solution and not form a precipitate with the other salts. The lactate has been selected as the least objectionable in this respect, and the combination with the alkaline citrate is with the view of retaining the salts in solution in the syrup. Cloudiness in the syrup may be prevented, according to Ott, by dissolving the ferrous lactate and potassium citrate in hot syrup and adding this to the syrup of hypophosphites. This syrup of hypophosphites with iron contained in each fluidrachm about two and a half grains of calcium hypophosphite, with nearly one grain each of sodium and potassium hypophosphites, and three-fourths of a grain of ferrous lactate. It unites the therapeutic powers of a chalybeate with those of the hypophosphites. Dose, from one to two fluidrachms (3.7 to 7.5 Cc.).

Syrup of Hypophosphites with Iron.—Owing to the liability to change of ferrous lactate in the presence of an excess of hypophosphites, C. D. Randall substituted ferric citrate for it, with very good results, and gave the following process: Take of Calcium Hypophosphite 554 parts [or 591 grains]; Sodium Bicarbonate 95 parts [or 101 grains]; Potassium Bicarbonate 115 parts [or 123 grains]; Ferric Citrate 85 parts [or 91 grains]; Sugar, powdered, 4650 parts [or 9 trovounces]; Water a sufficient quantity to make 10,000 parts [or 16 fluidounces]. Dissolve the

calcium hypophosphite, previously reduced to a fine powder, in 3500 parts [or 8 fluidounces] of water with the aid of heat, and add to the solution the sodium bicarbonate, continuing the heat until action has entirely ceased. After removing the solution from the heat, add the potassium bicarbonate in small portions, waiting after each addition until effervescence has ceased before adding more. When action has entirely ceased, filter the liquid through paper. After the liquid has ceased to drop, add enough water through the filter to make the filtrate weigh 5850 parts [or measure 10 fluidounces]. In 1200 parts [or 2 fluidounces] of this liquid dissolve the ferric citrate with the aid of heat, and add the solution to the remainder of the liquid. In this solution dissolve the sugar with or without the aid of heat and filter through paper, adding through the filter enough water to make the completed syrup weigh 10,000 parts [or measure 16 fluidounces]. (*A. J. P.*, 1884, p. 357.)

passed, follow it with Water, until the product measures *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Mix thoroughly." U. S. By the U. S. process of 1850, a tincture of ipecac was first formed with diluted alcohol, then reduced by evaporation so as to drive off the alcohol, and afterwards diluted with water and made into a syrup with sugar. The French Codex dissolves the alcoholic extract of ipecac in water, and then mixes it with syrup, but it is obvious that the U. S. plan was preferable, as it spared the continued heat requisite to reduce the tincture to dryness. The present U. S. syrup, which is very slightly stronger than that of 1870, is made in accordance with the suggestions of Laidley of Richmond, Va., who found the syrup, as ordinarily prepared, to spoil by keeping. (*A. J. P.*, xxvi. 103, and July, 1879.) (See a practical paper on this subject by A. Robbins in *A. J. P.*, Aug. 1879.) The substitution of glycerin for a portion of the syrup in the U. S. process is an improvement, but the addition of the very small quantity of Acetic Acid is of questionable utility. For formulæ in which the drug ipecac is employed, the reader may consult *A. J. P.*, 1870, p. 127; 1871, p. 104; May, 1881.

If strictly official (8th Rev.) fluidextract of ipecac is used in making this syrup, and the process is carried out in all its details, the syrup will remain transparent; but if commercial fluidextract is used, or if the fluidextract has not been very carefully made, it will be necessary to modify the process somewhat to secure a transparent syrup. This may be effected by allowing the diluted fluidextract in the official process for making this syrup to remain for two or three days in a cool place before filtering, and adding to the sugar.

One fluidounce of this syrup should contain the virtues of about thirty grains of ipecac.

Dose, for an adult as an expectorant, from thirty minims to a fluidrachm (1.8 to 3.75 Ce.); as an emetic, half a fluidounce (15 Ce.).

SYRUPUS KRAMERÆ. U. S.

SYRUP OF KRAMERIA

(sy-rû'pûs krâ-mê'rî-æ)

Syrupus Ratanhiæ; Syrup of Rhatany; Sirop de Ratanhia, *Fr. Cod.*; Ratanhiásirup, G.

* "Fluidextract of Krameria, *four hundred and fifty cubic centimeters* [or 15 fluidounces, 104 minims]; Syrup, *five hundred and fifty cubic centimeters* [or 18 fluidounces, 287 minims], to make *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Mix them." U. S.

This syrup is more conveniently made by the present process than by either of those of the U. S. Pharmacopœia of 1860,—in the first of which the powdered root was exhausted with water, the percolate evaporated, and the sugar dissolved in it by a gentle heat, while in the second process, extract of krameria was dis-

solved in syrup. As krameria yields a variable proportion of extract, it follows that the syrup resulting from these two modes of preparation must have differed. To obviate this evil as far as possible, care had to be taken, in following the first process, to select the best krameria, and preferably the small roots, as it was these only which would yield two ounces of good extract to the pound. We have found the syrup made from the official fluidextract perfectly transparent, and not a turbid mixture, as stated by some writers. This preparation affords a convenient mode of exhibiting krameria.

Dose, for an adult, two fluidrachms (7.5 Ce.); for a child a year or two old, from ten to twenty minims (0.6 to 1.3 Ce.).

SYRUPUS LACTUCARII. U. S.

SYRUP OF LACTUCARIUM

(sy-rû'pûs lâc-tû-cá'rî-i)

Sirop de Lactucarium, *Fr.*; Lactucariumsirup, G.

* "Tincture of Lactucarium, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Glycerin, *two hundred cubic centimeters* [or 6 fluidounces, 366 minims]; Citric Acid, *one gramme* [or 15 grains]; Orange Flower Water, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Syrup, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Mix the Tincture of Lactucarium with the Glycerin, add the Orange Flower Water in which the Citric Acid has been previously dissolved, and filter, if necessary. Finally, add a sufficient quantity of Syrup to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Mix thoroughly." U. S.

The formula of the U. S. P. 1870 was very objectionable, and the syrup was rarely used, on account of its want of transparency, and in some measure also because of its disagreeable taste. The former of these objections it was proposed to obviate by the use of magnesium carbonate, as in the former U. S. formula for Syrup of Tolu; the latter, by the addition of one of the aromatic Waters. The rubbing with magnesium carbonate enabled the solvent to take up, as far as it was capable of doing, the matter that would otherwise have been deposited. The use of powdered pumice-stone instead of magnesium carbonate, and the rubbing of this and a little sugar with the tincture after evaporation instead of previously, were recommended by James Kenworthy. The result was a beautifully clear syrup,¹ with the flavor and

¹ *Aubergier's Syrup of Lactucarium*.—Though probably inferior in efficacy to the U. S. syrup, that of Aubergier has a great reputation on the continent of Europe, and is occasionally prescribed here instead of the official. It differs so much from ours that, when it is prescribed, pharmacists who may not have it on hand should not substitute the official for it, unless with the full knowledge of the prescriber. In order to obviate this inconvenience, it is advisable that there should be a formula, readily accessible, by which a syrup may be prepared sufficiently represent-

appearance of Auberger's, and the virtues of that of the U. S. Pharmacopœia. (*A. J. P.*, March, 1868, p. 113.) But the present process, if official tincture of lactucarium be used, is far preferable, the only disadvantage being the slight petroleum-like taste which seems to be inseparable from lactucarium preparations made by extracting the resinous principles with petroleum benzin; the new tincture of lactucarium, notwithstanding all the care that can be given to the purification of the petroleum benzin, will still hold a trace of the benzin-residue flavor, which it communicates to the syrup. The recommendations made by various pharmaceutical writers to add a solution of an alkali to cloudy syrup of lactucarium, in order to make it transparent, are inadmissible, for Auberger has conclusively shown that alkalies destroy the bitter principles of lactucarium.

Jos. W. England and N. D. Streeter both prefer to make the syrup directly from the lactucarium. For processes, see *A. J. P.*, 1883, pp. 393, 593.

Dose, two to three fluidrachms (7.5 to 11.25 Cc.).

SYRUPUS LIMONIS. Br.

SYRUP OF LEMON

(sy-rá'pūs lì-mō'nīs)

Syrupus Succus Citri; Sirop de Limon (de Citron), Sirop de suc de Limon (de citron), *Fr.*; Citronensirup, Citronensaftsirup, *G.*; Jarabe de limon, *Sp.*

"Fresh Lemon Peel, in thin slices or grated, 1 ounce (Imperial) or 20 grammes; Alcohol (90

ing Auberger's for all practical purposes. Procter, therefore, did the profession good service by preparing and publishing such a process, which we copy here. "Take of Lactucarium (German) half an ounce; Granulated Sugar an ounce; Simple Syrup four and a half pints; Citric Acid, in powder, sixty grains; Orange Flower Water four fluidounces; Diluted Alcohol, Water, each, a sufficient quantity. Triturate the Lactucarium with the Sugar until reduced to powder, put it into a funnel-shaped percolator, pour on Diluted Alcohol until the Lactucarium is nearly exhausted, or until ten fluidounces have passed, evaporate to two fluidounces, and add it to the Syrup, previously heated by boiling, and mix. Continue the ebullition slowly until the whole measures four pints and six fluidounces. Then add the Citric Acid and strain, and, lastly, when nearly cool, the Orange Flower Water, and mix them. Each fluidounce represents three and one-third grains of lactucarium. The syrup is light brown and transparent." (*A. J. P.*, 1866, p. 290.)

The French Codex has a syrup, called *Opiated Syrup of Lactucarium* (*Sirop de Lactucarium opiacé*), in which an alcoholic extract is used in double the quantity of extract of opium. One would suppose that in such a proportion the action of the opium would entirely overwhelm that of the lactucarium; but Geo. B. Wood was assured by Deschamps, as the well-ascertained result of experiments of his own and of Debout, that lactucarium given with opium, even in small proportion, very decidedly opposes the unpleasant effects caused by opium, such as nausea, stomachic spasms, headache, etc. (*Ann. Ther.*, 1868, p. 17), and hence the advantage of a preparation in which the two narcotics are combined. But to gain all the good results of this experience it is unnecessary to add a new syrup to the official list, all that is required being the addition of a little of the simple syrup of lactucarium to any preparation of opium the anticipated unpleasant effects of which it is desirable to prevent.

per cent.), a sufficient quantity; Lemon Juice, 25 fl. ounces (Imp. meas.) or 500 cubic centimetres; Refined Sugar, 38 ounces (Imp.) or 760 grammes. Macerate the Lemon Peel in one fluid ounce and a half (Imp. meas.) or thirty cubic centimetres of the Alcohol for seven days; press; filter; add sufficient of the Alcohol to produce two fluid ounces (Imp. meas.) or forty cubic centimetres. In the Lemon Juice, clarified by subsidence, dissolve the Refined Sugar by the aid of gentle heat. When the resulting syrup is cold, mix with it the two fluid ounces (Imp. meas.) or forty cubic centimetres of alcoholic liquid. The product should weigh four pounds and one ounce (Imp.) or thirteen hundred grammes." *Br.*

The U. S. P. 1880 syrup of lemon was dropped at the 1890 revision; as it is frequently used, the process will be found in the foot-note.¹ The addition of lemon peel to the preparation is an improvement, but the internal white portion of the peel should be carefully removed before adding to the hot lemon juice, or the finished syrup will have a bitter taste. (See *Limonis Cortex*.) This syrup forms a cooling and grateful addition to beverages in febrile complaints, and serves to conceal the taste of saline purgatives in solution.

SYRUPUS PICIS LIQUIDÆ. U. S.

SYRUP OF TAR

(sy-rá'pūs pī'cis liq'ui-dæ)

Syrupus cum aquâ piceâ; Syrupus Piceus; Sirop de Goudron, *Fr. Cod.*; Theersirup, *G.*; Jarabe de breia, *Sp.*

"Tar, five grammes [or 77 grains]; Alcohol, fifty cubic centimeters [or 1 fluidounce, 331 minims]; Magnesium Carbonate, ten grammes [or 154 grains]; Sugar, eight hundred and fifty grammes [or 29 ounces av., 430 grains]; Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix the Tar intimately, in a mortar, with ten grammes [or 154 grains] of clean white sand, add one hundred cubic centimeters [or 3 fluidounces, 183 minims] of Water, and, after kneading the mass thoroughly with the pestle, pour off the Water and throw it away. Treat the residue with the Alcohol, and, when the Tar is dissolved, add the Magnesium Carbonate and fifty grammes [or 1 ounce av., 334 grains] of Sugar, and after thorough trituration add four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Water; stir the mixture occasionally during two hours, and filter. Dissolve the re-

¹ "Lemon Juice, recently expressed and strained, forty parts [or seventeen fluidounces]; Fresh Lemon Peel, two parts [or one ounce av.]; Sugar, in coarse powder, sixty parts [or twenty-eight ounces av.]; Water, a sufficient quantity, to make one hundred parts [or about two pints]. Heat the Lemon Juice to the boiling point; then add the Lemon Peel, and let the whole stand, closely covered, until cold. Filter, add enough Water through the filter to make the filtrate weigh forty parts [or measure seventeen fluidounces], dissolve the Sugar in the filtered liquid by agitation, without heat, and strain." *U. S.* 1880.

mainder of the Sugar in the clear filtrate by gentle heat, strain, and add sufficient Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms].” U. S.

In many sections of our country this syrup has been largely used. The process of the U. S. P. (8th Rev.) is an improvement on the one formerly official. The proportion of tar has been reduced from 75 Gm. to 5 Gm. The washed tar is dissolved in alcohol, magnesium carbonate and a little sugar added, the mixture filtered, and more sugar dissolved with the aid of a gentle heat. The process is modelled after a method suggested by A. R. L. Dohme. The preliminary washing of the tar will doubtless be regarded by many as a useless refinement, but it should on no account be omitted, as otherwise a syrup which would be irritant rather than soothing might be produced, owing to the acid constituents always present in tar. (See *Pix Liquida*.) This syrup affords an excellent method of administering small quantities of tar.

Dose, from one to two fluidrachms (3.75 to 7.5 Cc.).

SYRUPUS PRUNI VIRGINIANÆ.

U. S., Br.

SYRUP OF WILD CHERRY

(sy-rá'pūs prā'nī vīr-gīn-i-ā'næ)

Syrup of Virginian Prune, Br. 1898; Sirop d'Ecorce de Cerisier, Fr.; Wildkirschenrindensirup, G.

* “Wild Cherry, in No. 20 powder, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Sugar, *seven hundred grammes* [or 24 ounces av., 303 grains]; Glycerin, *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims]; Water, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Moisten the Wild Cherry with a sufficient quantity of Water, and macerate for twenty-four hours in a covered vessel; introduce the Glycerin into a graduated receiving bottle; pack the Wild Cherry firmly in a cylindrical percolator, and gradually pour Water upon it; continue the percolation (shaking the percolate occasionally with the Glycerin), until the liquid measures *four hundred and fifty cubic centimeters* [or 15 fluidounces, 104 minims]. Dissolve the Sugar in the liquid by agitation, without heat, strain, and pass enough Water through the strainer to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Mix thoroughly. Syrup of Wild Cherry may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under *Syrupus*. Pour the percolate obtained as directed in the preceding formula upon the Sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it with Water,

until the product measures *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Mix thoroughly.” U. S.

“Virginian Prune Bark, in No. 20 powder, 3 ounces (Imperial) or 150 grammes; Refined Sugar, in coarse powder, 15 ounces (Imp.) or 750 grammes; Glycerin, $1\frac{1}{2}$ fl. ounces (Imp. meas.) or 62.5 cubic centimetres; Distilled Water, *a sufficient quantity*. Moisten the Virginian Prune Bark with Distilled Water; set aside for twenty-four hours in a closed vessel; pack in a percolator; gradually add Distilled Water until the quantity of *nine fluid ounces* (Imp. meas.) or four hundred and fifty cubic centimetres of percolate has been collected; dissolve the Refined Sugar in the liquid by agitation, without heat; add the Glycerin; strain; pour sufficient Distilled Water over the strainer to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Syrup.” Br.

The British Pharmacopœia introduced this syrup into the 1898 edition. The process is modelled after the U. S. formula.

The U. S. process affords a handsome syrup, with the virtues of the bark unimpaired by the injurious effects of heat. It is based upon a formula proposed by Procter and Turnpenny in *A. J. P.*, xiv. 27. The introduction of the glycerin into the receiving bottle instead of mixing it with the menstruum is an improvement adopted from the Br. process; the glycerin is not needed in the menstruum to increase the astringency of the syrup but it serves a useful purpose in keeping the infusion from decomposing and precipitating a reddish, insoluble substance in the receiving bottle. This syrup should never be made by adding fluidextract to simple syrup, as the fluidextract is likely to vary greatly in quality, and frequently precipitates when mixed with syrup, the syrup when made by the above process is far superior in flavor and active properties, and is largely used as a basis for cough mixtures.¹

Dose, half a fluidounce (15 Cc.).

SYRUPUS RHEI. U. S., Br.

SYRUP OF RHUBARB

(sy-rá'pūs rhē'ī)

Sirop de Rhubarbe, Fr.; Sirupus Rhei, P. G.; Rhubarbersirup, Rhubarbersaft, G.

* “Fluidextract of Rhubarb, *one hundred cubic centimeters* [or 3 fluidounces, 183 min-

¹Acetous Syrup of Wild Cherry.—Joseph P. Remington devised the following process for this form of syrup, which he believes possesses some advantages over the official syrup, particularly in that the astringency is greatly modified: Moisten 150 Gm. of wild cherry in No. 20 powder, with 50 Cc. of diluted acetic acid, U. S. P.; macerate for twenty-four hours in a close glass or earthenware vessel, pack in a non-metallic percolator, and percolate with diluted acetic acid into a receiver containing 150 Cc. of glycerin until 450 Cc. of liquid are obtained. In this dissolve 700 Gm. of sugar without heat; strain, and pass enough diluted acetic acid through the strainer to make 1000 Cc. of finished syrup. The product is light reddish-brown, has the characteristic peach-kernel flavor, and a decidedly agreeable, acidulous taste. (*A. J. P.*, May, 1899, 209-210.)

ims]; Spirit of Cinnamon, *four cubic centimeters* [or 65 minims]; Potassium Carbonate, *ten grammes* [or 154 grains]; Water, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Syrup, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Spirit of Cinnamon with the Fluidextract of Rhubarb, and add to it the Potassium Carbonate previously dissolved in the Water, and lastly enough Syrup to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." *U. S.*

"Rhubarb Root, in No. 20 powder, 2 ounces (Imperial) or 50 grammes; Coriander Fruit, in No. 20 powder, 2 ounces (Imp.) or 50 grammes; Refined Sugar, 24 ounces (Imp.) or 600 grammes; Alcohol (90 per cent.), 8 fl. ounces (Imp. meas.) or 200 cubic centimetres; Distilled Water, 24 fl. ounces (Imp. meas.) or 600 cubic centimetres. Moisten the mixed Rhubarb Root and Coriander Fruit with a portion of the mixed Alcohol and Distilled Water, and set aside; pack in a percolator; pass the remainder of the diluted alcohol slowly through the materials; evaporate the percolate until it is reduced to *fourteen fluid ounces* (Imp. meas.) or three hundred and fifty cubic centimetres, and in this, after it has been filtered, dissolve the Refined Sugar by the aid of heat. The product should weigh nearly *two and a half pounds* (Imp.) or one thousand grammes." *Br.* This is a troublesome and imperfect method.

The U. S. syrup differs from that official before 1890 in several particulars, and, in our opinion, it is greatly improved; the activity of the rhubarb and the corrigent effects of the cinnamon are both secured without impairing the appearance of the finished syrup, while the simplicity of the manipulation must commend the process to all. Otto Miller recommends its preparation by dissolving ninety grains of potassium carbonate in twelve fluidounces of cinnamon water, adding twenty-eight ounces of sugar, heating to the boiling point, and, when the sugar is dissolved, adding four fluidounces of fluidextract of rhubarb, straining, and bringing it to the measure of two pints with cinnamon water. A pleasant, clear, efficient, and permanent syrup results. (*West. Drug.*, 1887, p. 107.)

The official syrup is a mild cathartic, adapted to the cases of infants, to which it may be given in the dose of a fluidrachm (3.75 Cc.).

Dose, for adults, two to three fluidrachms (7.5 to 11 Cc.).

SYRUPUS RHEI AROMATICUS. U. S.

AROMATIC SYRUP OF RHUBARB

(sy-rá'pūs rhē'i ār-q-māt'cūs)

Spiced Syrup of Rhubarb; Sirop de Rhubarbe aromatique, *Fr.*; Gewürzter Rhubarbersaft, *G.*

*"Aromatic Tincture of Rhubarb, *one hundred and fifty cubic centimeters* [or 5 fluid-

ounces, 35 minims]; Potassium Carbonate, *one gramme* [or 15 grains]; Syrup, *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims], to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the Potassium Carbonate in the Aromatic Tincture of Rhubarb. Filter, if necessary, and add sufficient Syrup to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." *U. S.*

This syrup is nearly identical with that official in the U. S. P. 1870. The aromatic tincture is identical with that formerly used in the preparation of this syrup. The addition of a small amount of alkali has been adopted, to prevent the syrup from becoming turbid. The substitution of glycerin for one-half of the syrup, as recommended in the 14th edition of this work, would be an improvement.

The aromatic syrup of rhubarb is a warm stomachic laxative, too feeble for adult cases, but well calculated for the bowel complaints of infants; which are so frequent in our cities during the summer season, and as a remedy for which this preparation, or one analogous to it, has been long in use, under the name of *spiced syrup of rhubarb*. The dose for an infant with *diarrhœa* is a fluidrachm (3.75 Cc.), repeated every two hours until the passages indicate by their color that the medicine has operated. It should be borne in mind that the syrup, as prepared by the present formula, contains one-seventh of diluted alcohol, which, though not injurious in most cases in which this syrup is used, might render it too stimulating in some instances of *diarrhœa* in the very young infant.

Dose, one to two fluidrachms (3.75 to 7.5 Cc.).

SYRUPUS RHÆADOS. Br.

SYRUP OF RED POPPY

(sy-rá'pūs rhæ'a-dōs)

Sirop de Coquelicot, *Fr. Cod.*; Sirop de Pavot rouge, *Fr.*; Katschroensafft, *G.*

"Red-Poppy Petals, 13 ounces (Imperial) or 260 grammes; Refined Sugar, 2½ pounds (Imp.) or 720 grammes; Alcohol (90 per cent.), 2½ fl. ounces (Imp. meas.) or 50 cubic centimetres; Distilled Water, *a sufficient quantity*. Add the Red-Poppy Petals gradually to *one pint* (Imp. meas.) or four hundred cubic centimetres of Distilled Water kept hot upon a water-bath; stir frequently, and afterwards, the vessel being removed, infuse for twelve hours. Then press out the liquid; strain; add the Refined Sugar, and dissolve by the aid of heat. When nearly cold, add the Alcohol, and sufficient Distilled Water to produce *three pounds ten ounces* (Imp.) or one thousand one hundred and sixty grammes of the Syrup." *Br.*

The object of introducing the petals into water heated by a water bath is that they may shrink by being scalded, as otherwise they

could not be completely immersed in the quantity of water directed. After this has been accomplished, they should be immediately removed from the fire, lest the liquor become too thick and ropy. The fine red color of this syrup is its only recommendation. It is very liable to ferment; according to Enders, this can be obviated by evaporating the recently prepared syrup to dryness, keeping the powdered residue in well-stoppered bottles, and dissolving it, as wanted, in four-fifths of its weight of water.

Dose, as stated in the Br. Pharmacopœia, one-half to one fluidrachm (1.8 to 3.75 Ce.).

SYRUPUS ROSÆ. U. S., Br.

SYRUP OF ROSE

(sy-rû'pûs rô'sæ)

Syrup of Roses, Br.; Syrupus Rosarum Rubrarum; Syrup of Red Rose; Sirop de Rose rouge, Fr.; Rosensirup, G.

* "Fluidextract of Rose, *one hundred and twenty-five cubic centimeters* [or 4 fluidounces, 109 minims]; Diluted Sulphuric Acid, *ten cubic centimeters* [or 162 minims]; Sugar, *seven hundred and fifty grammes* [or 26 ounces av., 199 grains]; Water, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Fluidextract of Rose and Diluted Sulphuric Acid with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water; after allowing the mixture to stand two hours, filter, and dissolve the Sugar in the clear filtrate, by agitation. Finally, add a sufficient quantity of Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Strain, if necessary." U. S.

"Dried Red-Rose Petals, *2 ounces* (Imperial) or 50 grammes; Refined Sugar, *30 ounces* (Imp.) or 750 grammes; Distilled Water, boiling; *1 pint* (Imp. meas.) or 500 cubic centimetres. Infuse the Red-Rose Petals in the Distilled Water for two hours; strain; press; heat the liquid to the boiling point; filter; dissolve the Refined Sugar in the liquid by the aid of heat. The product should weigh *two pounds fourteen ounces* (Imp.) or eleven hundred and fifty grammes." Br.

Syrup of rose is mildly astringent, but is valued most for its fine red color, on account of which it is occasionally added to mixtures. The color is developed by the small amount of diluted sulphuric acid which is added.

Dose, a fluidrachm (3.75 Ce.).

SYRUPUS RUBI. U. S.

SYRUP OF RUBUS

(sy-rû'pûs rû'bî)

Syrup of Blackberry Bark. Syrup of Blackberry Root; Sirop d'Ecorce de Ronce, Fr.; Brombeersirup, G.

* "Fluidextract of Rubus, *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims]; Syrup, *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims], to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix them." U. S.

This syrup is useful in *acute diarrhœa of relaxation* and in *chronic diarrhœa*.

Dose, from one to two fluidrachms (3.75 to 7.5 Ce.).

SYRUPUS SARSAPARILLÆ COMPOSITUS. U. S.

COMPOUND SYRUP OF SARSAPARILLA

(sy-rû'pûs sâr-sa-pa-ril'la com-pôs'q'i-tûs)

Syrupus Sudorificus; Sirop de Salsepareille composé, Fr. Cod.; Sirop sudorifique, Fr.; Zusammengesetzter Sarsaparillasirup, G.; Jarabe de zarzaparrilla compuesto, Sp.

* "Fluidextract of Sarsaparilla, *two hundred cubic centimeters* [or 6 fluidounces, 366 minims]; Fluidextract of Glycyrrhiza, *fifteen cubic centimeters* [or 243 minims]; Fluidextract of Senna, *fifteen cubic centimeters* [or 243 minims]; Sugar, *six hundred and fifty grammes* [or 22 ounces av., 406 grains]; Oil of Sassafras, *two-tenths of a cubic centimeter* [or 3 minims]; Oil of Anise, *two-tenths of a cubic centimeter* [or 3 minims]; Oil of Gaultheria, *two-tenths of a cubic centimeter* [or 3 minims]; Water, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Add the Oils (equivalent to about *four drops* each) to the mixed Fluidextracts and shake the liquid thoroughly. Then add enough Water to make up the volume to *six hundred cubic centimeters* [or 20 fluidounces, 138 minims], and mix well. Set the mixture aside for one hour, and then filter it. Dissolve the Sugar in the filtrate with the aid of a gentle heat, allow the liquid to cool, strain, and add enough Water, through the strainer, to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." U. S. An important change was made in this compound syrup in the U. S. P. 1890, through the substitution of fluidextracts and volatile oils for the drugs used in the U. S. P. 1880 process. It was further improved in the Eighth Revision by doubling the amount of volatile oils. The new syrup is not perfectly transparent, but the U. S. P. 1880 syrup had the same fault. The simplicity of the present formula is a welcome improvement.

In the original edition of the U. S. Pharmacopœia, published in 1820, a process for a syrup of sarsaparilla was adopted, intended to represent the famous French *sirop de cuisinier*. This was very much improved in the revised edition published in 1830, and the amended process has been retained with little alteration in the subsequent editions, the process of percolation having been substituted in the U. S.

1880 Pharmacopœia for simple maceration directed in the first of the two formulas of 1850. In the original process the sarsaparilla was subjected to long decoction with water. It has been proved that diluted alcohol more thoroughly extracts the acrid principle of the root, upon which its activity probably depends, than water, and that this principle is either dissipated or destroyed by the long-continued application of a boiling heat. In the present formula, therefore, which employs alcohol in the menstruum for the fluidextracts, the root is more completely exhausted of its active matter, while the heat applied to the concentration, being no higher than is requisite for the evaporation of the alcohol, is insufficient to injure the preparation. The spirituous menstruum has, moreover, the advantage of not dissolving the inert fecula, which encumbers the syrup prepared by decoction and renders it liable to spoil. The essential oils were intended solely to communicate an agreeable flavor, and were used in very small proportion. The only objection to the 1880 process was that a portion of the resin extracted by the alcohol from the guaiacum wood was deposited during the evaporation of the tincture; this was separated by the filtration directed in the U. S. P. 1880, and was therefore of no disadvantage to the preparation. In the present process guaiacum wood is omitted; its loss, however, will never be felt. But the practitioner should be aware that much of the sarsaparilla as it exists in the market is nearly or quite inert, and should be prepared to meet with disappointment in the use of this or any other preparation, unless satisfied of the good quality of the drug from which it is made.

Corrosive sublimate, which is often given in connection with this syrup, is said to be completely decomposed by it, being converted into calomel. Samuel Kennedy (*Ph. Rec.*, 1888, p. 201) showed that when corrosive sublimate was dissolved in this syrup precipitation invariably occurred; if an equal amount of sodium chloride was added, precipitation was greatly retarded. Lepage of Gisors, proposes as a substitute potassium iodohydrargyrate, which he has found not to undergo decomposition. (See *Potassio-mercuric iodide* PART II, and *Sirop Gibert*, p. 630.) When a decided effect is desired, the fluidextract is much more efficient.

Dose, of the syrup, half a fluidounce (15 Cc.), equivalent to somewhat less than a drachm (3.9 Gm.) of the root, to be taken three or four times a day.

SYRUPUS SCILLÆ. U. S., Br.

SYRUP OF SQUILL

(sy-râ'pūs scil'læ)

Syrupus Aceti Scillæ; Sirop de Scille, *Fr.*; Meerzwiebelisirup, *G.*

* "Vinegar of Squill, *four hundred and fifty cubic centimeters* [or 15 fluidounces, 104 min-

ims]; Sugar, *eight hundred grammes* [or 28 ounces av., 96 grains]; Water, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the Sugar in the Vinegar of Squill with the aid of a gentle heat, then strain, and, when the strained liquid is cold, add enough Water, through the strainer, to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." *U. S.*

"Vinegar of Squill, 1 pint (Imperial measure) or 500 cubic centimetres; Refined Sugar, 38 ounces (Imp.) or 950 grammes. Dissolve the Refined Sugar in the Vinegar of Squill by the aid of gentle heat. The product should weigh *three pounds ten ounces* (Imp.) [or one thousand four hundred and fifty grammes]." *Br.*

The present British formula is almost identical with the U. S. (8th Rev.), and differs from that of 1864 in taking the vinegar already formed, instead of preparing it as the first step of the process. The object of heating the vinegar to the boiling point is to coagulate albuminous matter, which is afterwards separated by filtration. The heating should be performed as quickly as possible, to prevent undue loss of acetic acid.

This syrup is much employed as an expectorant, especially in combination with a solution of tartarized antimony. It is incompatible with ammonium carbonate, but not with ammonium chloride.

Dose, about a fluidrachm (3.75 Cc.). In infantile *bronchitis* it is sometimes given, in the same dose, as an emetic.

SYRUPUS SCILLÆ COMPOSITUS.

U. S.

COMPOUND SYRUP OF SQUILL

(sy-râ'pūs scil'læ cōm-pōs'it-ūs)

Hive Syrup; Sirop de Scille composé, *Fr.*; Zusammengesetzter Meerzwiebelisirup, *G.*

* "Fluidextract of Squill, *eighty cubic centimeters* [or 2 fluidounces, 338 minims]; Fluidextract of Senega, *eighty cubic centimeters* [or 2 fluidounces, 338 minims]; Antimony and Potassium Tartrate, *two grammes* [or 31 grains]; Purified Tale, *twenty grammes* [or 309 grains]; Sugar, *seven hundred and fifty grammes* [or 26 ounces av., 199 grains]; Water, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Fluidextracts, evaporate them, in a tared dish, on a water-bath, to *one hundred grammes* [or 3 ounces av., 231 grains], and mix the residue with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of Water. When the mixture is cold, incorporate with it, intimately, the Purified Tale, filter, pass enough Water through the filter to obtain *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of clear filtrate, and add to this the

Antimony and Potassium Tartrate previously dissolved in *twenty-five cubic centimeters* [or 406 minims] of hot Water. Dissolve the Sugar in this liquid by agitation, without heat, strain, and add enough Water, through the strainer, to make the produce measure *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Mix thoroughly. Compound Syrup of Squill may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under *Syrupus*. Pour the filtrate obtained as directed in the preceding formula, and mixed with the solution of Antimony and Potassium Tartrate, upon the Sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it with Water, until the product measures *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Mix thoroughly." *U. S.*

This is intended as a substitute for the popular preparation called *Coxe's hive syrup*, from which it differs chiefly in containing sugar instead of honey. Prepared as originally directed in the Pharmacopœia, it invariably fermented from the want of sufficient concentration. This defect was corrected at the revision of 1840, when sugar was substituted for honey, in consequence of the uncertain consistence and constitution of the latter. In the Pharmacopœia of 1850 two formulas were given for this syrup, in the first of which the virtues of the squill and senega were extracted by long boiling with water, in the second by percolation with water to which a small portion of alcohol was added. The latter was preferable when skilfully performed, as it avoided in great measure the injurious influence upon the senega of boiling, exhausted both this and the squill more readily in consequence of the addition of alcohol to the menstruum, and afforded a solution of their active principles less embarrassed with inert matters calculated to favor fermentation. In this process the filtered liquor was raised to the boiling point in order to coagulate the albumen, after which the evaporation was conducted at a lower temperature. The present formula is a decided improvement upon the one just described, as, diluted alcohol being employed as the menstruum, less of the albuminous and mucilaginous matter is extracted, while any disadvantage from the spirituous addition is obviated by the subsequent evaporation of the alcohol and the addition of water, the provision being retained to boil the tincture for a short time to get rid of such albumen as has been taken up. Sometimes the amount of albuminous coagulum is so great as to render the process of filtration after the boiling very tedious. According to J. C. Wharton, this can be remedied by rubbing up the muddy liquid with magnesia (*A. J. P.*, xliii. 102); to serve the same purpose precipitated calcium phosphate was substituted in the *U. S. P.* 1890, but in the *U. S. P.* (8th Rev.) purified tale is used. Percolation we have found

very well adapted for dissolving the sugar and producing a transparent syrup. The present *U. S. P.* process has the merit of simplicity, but, unfortunately, the fluidextract of squill is never a wholly satisfactory preparation, and at present is made with a diluted acetic acid as a menstruum.

C. A. Werckshagen proposes the following modification. Evaporate one pint of vinegar of squill to the consistence of a soft extract, to remove the acetic acid, then add eighteen fluidounces of simple syrup, and apply heat; when clear, add twenty-four grains of tartar emetic and stir until dissolved; then take off the fire and add sufficient syrup to make the whole measure twenty-two fluidounces; lastly, when cold, add two fluidounces of fluidextract of senega. If the fluidextract of senega be exactly neutralized with ammonia, no gelatinization can occur. (*A. J. P.*, 1886, p. 591.)

Compound syrup of squill combines the virtues of senega, squill, and tartar emetic, of the last of which it contains about one grain in a fluidounce. It is emetic, diaphoretic, expectorant, and frequently cathartic, and may be given with advantage in mild cases of croup, also in the latter stages of severe cases when the object is to promote expectoration. In croup, however, a mineral emetic is much to be preferred. The dose of this syrup is, for children, from ten minims to a fluidrachm (0.6 to 3.75 Cc.), according to the age, and it may be repeated in cases of croup every fifteen or twenty minutes until it causes vomiting.

Dose, for adults as an expectorant, from twenty to thirty minims (1.3 to 1.8 Cc.).

SYRUPUS SENEGÆ. *U. S.*

SYRUP OF SENEGA

(sy-rû'pūs sên'ē-gæ)

Sirup de Polygala, *Fr.*; Sirupus Senegae, *P. G.*; Senegasirup, *G.*

* "Fluidextract of Senega, *two hundred cubic centimeters* [or 6 fluidounces, 366 minims]; Syrup, *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims], to make *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Mix them." *U. S.*

The syrup affords a very convenient mode of exhibiting senega in pectoral complaints. Owing to the pectinous principle present in senega, the syrup made directly from the root as in the process of 1870 was always turbid. It has been frequently pointed out that the addition of an alkali renders the syrup transparent, and the 1890 process directed the use of a small quantity of ammonia water, although, if the fluidextract of senega which contains alkali be used as in the *U. S. P.* (8th Rev.), this addition is unnecessary. This syrup may be given as a stimulant expectorant.

Dose, one or two fluidrachms (3.75 or 7.5 Cc.).

SYRUPUS SENNÆ. U. S., Br.

SYRUP OF SENNA

(sy-rû'pūs sēn'nx)

Sirop de Séné, *Fr.*; Sirupus Sennæ, *P. G.*; Sennasirup, *G.*

* "Fluidextract of Senna, *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims]; Oil of Coriander, *five cubic centimeters* [or 81 minims]; Syrup, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Oil of Coriander with the Fluidextract of Senna and add a sufficient quantity of Syrup to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." *U. S.*

"Senna, 40 ounces (Imperial) or 1200 grammes; Oil of Coriander, 10 minims or 0.6 cubic centimetre; Alcohol (90 per cent.), 40 minims or 2.4 cubic centimetres; Refined Sugar, in powder, 50 ounces (Imp.) or 1500 grammes; Alcohol (20 per cent.), 70 fl. ounces (Imp. meas.) or 2100 cubic centimetres. Moisten the Senna with *two pints* (Imp. meas.) or twelve hundred cubic centimetres of the Alcohol; pack tightly in a vessel which can afterwards be closed; set aside for three days; press strongly; reserve the liquid obtained; break up the marc; moisten it with *fifteen fluid ounces* (Imp. meas.) or four hundred and fifty cubic centimetres of the Alcohol; set aside for twenty-four hours; press strongly; add the liquid obtained to the portion previously preserved; break up the marc; mix it with the remainder of the Alcohol; set aside for three hours; press again; evaporate the resulting liquid until it is reduced to such a volume that when added to the reserved liquid the whole shall measure *two pints* (Imp. meas.) or twelve hundred cubic centimetres. Mix the evaporated liquid with the reserved liquid; heat the product in a covered vessel to 180° F. (82.2° C.) for a few minutes; set aside for twenty-four hours; filter; pass Distilled Water through the filter until the filtrate measures *forty fluid ounces* (Imp. meas.) or twelve hundred cubic centimetres; add the Refined Sugar, and dissolve in a covered vessel by the aid of gentle heat; cool; add the Oil of Coriander dissolved in the Alcohol (90 per cent.); shake well. The product should weigh *five pounds twelve ounces* (Imp.) or two thousand seven hundred and sixty grammes." *Br.*

The U. S. P. 1890 syrup resembled that of the British Pharmacopœia except in the important matter of strength; it contained only one-half the quantity of senna ordered for the British syrup, and was about one-third weaker than the U. S. 1880 syrup. This is, however, not a disadvantage, as the former syrups were nearly of the strength of the fluidextract. The process was improved in the U. S. P. (8th Rev.) by simply adding the fluidextract (made by the official method which deprived it of the griping principle) and oil of coriander to syrup.

Dose, for an adult, from two to four fluidrachms (7.5 to 15 Ce.); for children, for whom it was originally intended, not more than from one-eighth to one-half of that quantity, according to the age.

SYRUPUS TOLUTANUS. U. S., Br.

SYRUP OF TOLU

(sy-rû'pūs töl-û-tā'nūs)

Sirop de Baume de Tolu, *Fr. Cod.*; Sirop balsamique, *Fr.*; Tolubalsamsirup, *G.*; Jarabe de balsamo de Tolu, *Sp.*

* "Tincture of Tolu, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Magnesium Carbonate, *ten grammes* [or 154 grains]; Sugar, *eight hundred and twenty grammes* [or 28 ounces av., 405 grains]; Water, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Rub the Tincture of Tolu, in a mortar, with the Magnesium Carbonate and *sixty grammes* [or 2 ounces av., 51 grains] of the Sugar. Then gradually add *four hundred and fifty cubic centimeters* [or 15 fluidounces, 104 minims] of Water, with constant trituration, and filter. Dissolve the remainder of the Sugar in the clear filtrate, with the aid of a gentle heat, strain the Syrup while hot, and add a sufficient quantity of Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Syrup of Tolu may also be made in the following manner: Prepare a percolator or funnel in the manner described under *Syrupus*. Pour the filtrate obtained as directed in the preceding formula upon the Sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it with Water, until the product measures *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." *U. S.*

"Balsam of Tolu, 1½ ounces (Imperial) or 62.5 grammes; Refined Sugar, 2 pounds (Imp.) or 1600 grammes; Distilled Water, *a sufficient quantity*. Boil the Balsam of Tolu in *one pint* (Imp. meas.) or eight hundred cubic centimetres of the Distilled Water for half an hour in a lightly covered vessel, stirring frequently. Then remove from the source of heat and add Distilled Water, if necessary, so that the liquid when cold shall measure *sixteen fluid ounces* (Imp. meas.) or eight hundred cubic centimetres. Filter the solution, add the Refined Sugar, and dissolve by the aid of a water-bath. The product should weigh *three pounds* (Imp.) or two thousand four hundred grammes." *Br.*

The U. S. 1890 process for this syrup was more satisfactory than that formerly official. It was practically a return to the U. S. 1870 method (based on Finley's process¹), substi-

¹ *Syrupus Tolutanus*, U. S. 1870.—"Take of Tincture of Tolu *two fluidounces*; Carbonate of Magnesium *one hundred and twenty grains*; Sugar [Refined], in coarse powder, *twenty-six troyounces*;

tuting precipitated calcium phosphate for magnesium carbonate, and using a freshly made strong tincture for the official tincture of tolu.

The U. S. Pharmacopœia (8th Rev.) process reintroduced magnesium carbonate with much advantage, and has the further improvement of using the official tincture of tolu instead of making the latter from the balsam by a special process. In the British process the soluble principles of the balsam are extracted by boiling it with water, but with great waste of the material, as the water dissolves but a small portion of the active matter. To obviate this waste, the same portion of balsam is, according to Brande, usually employed in successive operations, and it long continues to impart odor and taste to boiling water. W. H. Hostelley's modification is as follows: For making twenty-five ounces of syrup, take one ounce of balsam of tolu, one pound of granulated sugar, and water which has been previously filtered through animal charcoal, enough to make twenty-five ounces; rub the tolu to a fine powder, aided by some of the sugar, and mix this with the remainder of the granulated sugar; now prepare a percolator by placing a piece of cotton in the neck, pack the powder in it, pour in the filtered water, and receive twenty-five ounces of percolate. (*A. J. P.*, 1887, p. 290.) Syrup of tolu is a feeble preparation and is used chiefly to impart its agreeable flavor to mixtures. If a stronger syrup is desired, it is readily made by adding tincture of tolu in the desired quantity and directing the bottle to be shaken.

SYRUPUS ZINGIBERIS. U. S., Br.

SYRUP OF GINGER

(sy-rá'pūs zīn-gīb'ē-rīs)

Sirop de Gingembre, *Fr.*; Ingwersirup, *G.*

* "Fluidextract of Ginger, *thirty cubic centimeters* [or 1 fluidounce, 7 minims]; Alcohol, *twenty cubic centimeters* [or 325 minims]; Magnesium Carbonate, *ten grammes* [or 154 grains]; Sugar, *eight hundred and twenty grammes* [or 28 ounces av., 405 grains]; Water, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Fluidextract of Ginger and the Alcohol, then triturate the liquid in a mortar with the Magnesium Carbonate and *sixty grammes* [or 2 ounces av., 51 grains] of the Sugar. Then gradually add *four hundred and fifty cubic centimeters* [or 15 fluidounces, 104 minims] of Water, with constant trituration, and filter. Dissolve the remainder of the Sugar in the clear

filtrate, with the aid of a gentle heat, strain the Syrup while hot, and add a sufficient quantity of Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Syrup of Ginger may also be made in the following manner: Prepare a percolator or funnel in the manner described under *Syrupus*. Pour the filtrate obtained as directed in the preceding formula upon the Sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it with Water, until the product measures *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." *U. S.*

"Ginger, in fine powder, ½ ounce (Imperial) or 12.5 grammes; Alcohol (90 per cent.), Syrup, of each *a sufficient quantity*. Prepare *one fluid ounce* (Imp. meas.) or twenty-five cubic centimetres of a strong tincture of the Ginger by the process of percolation with the Alcohol. To this add sufficient of the Syrup to produce *twenty fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Syrup of Ginger." *Br.*

The U. S. P. process has been improved by the addition of magnesium carbonate as an aid in distributing the resinous fluidextract so as to facilitate its solution in water. It is practically a return to the U. S. 1870 method.¹

The British syrup, being made by the simple incorporation of the tincture with syrup, has of course all the strength of the ginger, but is inferior to the U. S. preparation in appearance and flavor. The old plan of using water as the menstruum for the drug has been abandoned, as the syrup thus made is encumbered with mucilage and starch, and consequently rendered more liable to decomposition. In order that the preparation may be of the proper strength, it is necessary that the fluidextract should have been made with the best Jamaica ginger. The syrup of ginger is much used as a warm stomachic addition to tonic and purgative infusions or mixtures, and to impart flavor particularly to carbonic acid water.

Dose, a fluidrachm (3.75 Ce.) or more.

TABELLÆ TRINITRINI. Br.

TRINITRIN TABLETS

(tā-bél'læ trī-nī'trī-nī)

Tablets of Nitroglycerin.

"Tablets of chocolate each weighing five grains (0.324 gramme) and containing one-hundredth of a grain (0.00065 gramme) of the

Water a pint. Rub the Tincture of Tolu first with the Carbonate of Magnesium and two troyounces of the Sugar, and then with the Water, gradually added, and filter. To the filtered liquid add the remainder of the Sugar, and, having dissolved it with the aid of a gentle heat, strain the solution while hot." *U. S.* 1870.

S.* 1870.—"Take of Fluid Extract of Ginger a fluidounce; Carbonate of Magnesium one hundred and sixty grains; Sugar [refined], in coarse powder, seventy-two troyounces; Water forty-two fluidounces. Rub the Fluid Extract of Ginger first with the Carbonate of Magnesium and two troyounces of the Sugar, and then with the Water, gradually added, and filter. To the filtered liquid add the remainder of the Sugar, and, having dissolved it with the aid of a gentle heat, strain the solution while hot." *U. S.* 1870.

trinitroglycerin of commerce." Br. Each of these tablets contains a dose of the remedy. For the properties of nitroglycerin, see *Spiritus Glycerylis Nitratis*, page 1175.

TALCUM. U. S.

TALC

(tāl'cūm)

"A native hydrous magnesium silicate." U. S.

Talcum Venetum; Soapstone; Talc, *Fr. Cod.*; Talc de Venise, Craie de Briançon, *Fr.*; Talcum, *P. G.*; Talk, Talkstein, Speckstein, *G.*

Talc occurs in irregular masses of a greenish-grey color, having a peculiar wax-like appearance of the surface, and giving, when rubbed, a greasy sensation to the fingers. It is found in America and other parts of the world, the best quality at this time (1906) being obtained from New York and North Carolina. In 1905, the total production in the United States was 107,134 short tons, valued at \$1,106,062, of which 67,000 tons valued at \$469,000 came from New York State; most of the fibrous talc is used in the manufacture of paper.

Properties.—It is officially described as "a white or grayish-white powder or grayish-green irregular masses of waxy lustre; when rubbed upon the skin it imparts a feeling like greasiness; permanent in the air. Inodorous and tasteless. Insoluble in water, and in dilute solutions of the acids and alkali hydroxides. Specific gravity: 2.2 to 2.8. Mix 0.5 Gm. of Talc with about 2 Gm. each of anhydrous sodium and potassium carbonates, heat the mixture in a platinum crucible until fusion is complete, and treat the resulting fused mass with hot water; then neutralize the liquid with diluted sulphuric acid, and, after adding an additional 10 Cc. of the latter, evaporate the mixture until the white fumes of sulphuric anhydride are evolved, then add 20 Cc. of water, and, after boiling the mixture and filtering, an insoluble residue of silica should be left. If to the filtrate ammonia water and ammonium chloride T.S. be added, a white, gelatinous precipitate of aluminum hydroxide may be formed, while the filtrate from this, upon the addition of sodium phosphate T.S., should yield a white, crystalline precipitate (magnesium salts). If 1 Gm. of Talc be boiled with 25 Cc. of diluted hydrochloric acid for one-half hour, adding water from time to time to maintain approximately the original volume, and the liquid filtered, then the filtrate should yield, upon evaporating to dryness, igniting, and quickly weighing, not more than 0.05 Gm. of residue." U. S.

Uses.—Talc has been introduced into the U. S. P. (8th Rev.) solely for use in making purified talc. Talc should be used in medicine or pharmacy, only in the form of purified talc, as the native product contains soluble and insoluble impurities from which it must be freed.

Off. Prep.—Talcum Purificatum, U. S.

TALCUM PURIFICATUM. U. S.

PURIFIED TALC

(tāl'cūm pū-rī-fī-cā'tūm)

Talc purifié, *Fr.*; Gereinigter Talc, *G.*

* "Talc, in fine powder, five hundred grammes [or 17 ounces av., 279 grains]; Hydrochloric Acid, seventy-five cubic centimeters [or 2 fluidounces, 257 minims]; Water, a sufficient quantity. Mix the powdered Talc with about twenty-five hundred cubic centimeters [or 5 pints] of boiling Water, gradually add fifty cubic centimeters [or 1 fluidounce, 331 minims] of the Hydrochloric Acid, and boil the mixture during fifteen minutes, then allow it to stand for fifteen minutes. Decant, and reject the supernatant liquid containing the finer particles of Talc in suspension, and again boil the residue with twenty-five hundred cubic centimeters [or 5 pints] of Water, mixed with the remainder of the Hydrochloric Acid, and allow it to stand for fifteen minutes. Again decant, and reject the finer suspended particles, and wash the coarser residue with Water by repeated decantation, until a portion of the wash-water, after filtering and acidifying with nitric acid, fails to become opalescent upon the addition of silver nitrate test solution. Then transfer the magma to a close linen or muslin strainer, allow it to drain, and dry it at 110° C. (230° F.)." U. S. For pharmaceutical purposes powdered talc requires purification to extract iron salts and other impurities. The official process rejects the finest particles, as they are a great annoyance to the pharmacist, owing to their passing through the pores of filtering paper, thus requiring repeated filtrations. (See *Aquæ*.) Purified Talc is intended to replace magnesium carbonate, calcium phosphate, and other absorbent powders used to aid filtration, it having the advantage of insolubility, although its absorbent properties are deficient in comparison with magnesium carbonate.

Properties.—It is officially described as follows: "Purified Talc, when subjected to ignition at red heat, should lose not more than 5 percent. of its weight. If 10 Gm. of Purified Talc be boiled with 50 Cc. of distilled water for one-half hour, adding water from time to time to maintain approximately the original volume, it should yield a filtrate which is neutral to litmus paper, and one-half of this filtrate, when evaporated and dried at 110° C. (230° F.), should yield not more than 0.005 Gm. of residue (limit of soluble substances). The remaining half of the filtrate, after slightly acidulating with hydrochloric acid, should not yield a blue color upon the addition of potassium ferrocyanide T.S. (absence of iron)." U. S.

Uses.—Purified talc is used pharmaceutically (see above) and as a protecting, soothing powder to the skin. When in very fine powder it forms the basis of many of the proprietary preparations found on ladies' dressing tables,

and is very valuable as a dusting powder in *intertrigo*, *prickly heat*, *pruritus*, and other conditions of dermal irritation.

TAMARINDUS. U. S., Br.

TAMARIND

(tām-a-rin'dūs)

"The preserved pulp of the fruit of *Tamarindus indica* Linné (Fam. *Leguminosæ*)."
U. S. "The fruits of *Tamarindus indica*, Linn., freed from the brittle outer part of the pericarp and preserved with sugar." Br.

Fructus Tamarindorum; Tamarinier, *Fr. Cod.*; Tamarin, Pulpe brute de Tamarins, *Fr.*; Pulpa Tamarindorum cruda, *P. G.*; Tamarindemnus, Tamarinden, *G.*; Tamarindo, *It.*; Tamarindo (Pulpa de), *Sp.*

Tamarindus indica, L., *Sp. Pl.* (1753) 180; Willd., *Sp. Plant.* iii. 577; B. & T. 92.—The tamarind tree is the only species of this genus. It rises to a great height, sends off numerous spreading branches, and has a beautiful appearance. The trunk is erect, thick, and covered with a rough, ash-colored bark. The leaves are alternate and pinnate, composed of many pairs of opposite leaflets, which are almost sessile, entire, oblong, obtuse, unequal at their base, about half an inch long by a sixth of an inch broad, and of a dark-green color. The flowers, which are in small lateral racemes, have a yellowish calyx, and yellow petals beautifully variegated with red veins. The fruit is a broad, compressed, reddish-ash-colored pod, much curved, from two to six inches long, with numerous brown, flat, quadrangular seeds, contained in cells formed by a tough membrane. Exterior to this membrane is a light-colored acid pulpy matter, between which and the shell are several somewhat branched tough ligneous strings, running from the stem to the extremity of the pod, the attachment of which they serve to strengthen. The shells are fragile and easily separated. The tree appears to be a native of the East and West Indies, Egypt, and Arabia, though believed by some to have been imported into America. Barth, the African traveller, found it abundant in the interior of Africa. De Candolle was doubtful whether the East and West India trees are of the same species. It is stated by writers that the pods of the former are much larger than those of the latter, and have a greater number of seeds, the East India tamarinds containing six or seven, those from the West Indies rarely more than three or four; but this seems not to be correct.

Calcutta appears to be the chief emporium for the tamarinds of the European markets. Tamarinds are also sent from the West Indies and Ecuador to England; when from this source they are preferred. The latter are known as American tamarinds, and are obtained from *T. indica*, var. *occidentalis*, Gärtn. They are of a light brown color, less cohesive and possess less acidity than the tamarinds from the Old World. Tamarinds are brought

to us chiefly from the West Indies, where they are prepared by placing the pods, previously deprived of their shells, in layers in a cask, and pouring boiling syrup over them. A better mode, sometimes practised, is to place them in stone jars, with alternate layers of powdered sugar. They are said to be occasionally prepared in copper boilers. In the East Indies tamarinds are often prepared for market by stripping off the outer shell and pressing the pulpy interiors into a mass; sometimes they are packed as in the West Indies.

Properties.—Fresh tamarinds, which are sometimes, though rarely, brought to this country, have an agreeable, sour taste, without any mixture of sweetness. As we usually find them, in the preserved state, they form a dark-colored adhesive mass, consisting of syrup mixed with the pulp, membrane, strong, somewhat branching fibres or strings, and seeds of the pod, and having a sweet acidulous taste. The brown, flattish, quadrangular seeds, each enclosed in a tough membrane, should be hard, clean, and not swollen, the strings tough and entire, and the odor without mustiness. Tamarind is officially described as "a pulpy mass of a light reddish-brown color, darkening with age so as to become dark brown, containing some branching fibres and numerous reddish-brown, smooth, oblong or quadrangular, compressed seeds, each enclosed in a tough membrane; odor distinct; taste sweet and agreeably acid." U. S. From the analysis of Vauquelin, it appears that in 100 parts of the pulp of tamarinds, independently of the sugar added to them, there are 9.40 parts of citric acid, 1.55 of tartaric acid, 0.45 of malic acid, 3.25 of potassium bitartrate, 4.70 of gum, 6.25 of pectin, 34.35 of parenchymatous matter, and 27.55 of water. K. Müller (*Ph. Centralh.*, 1882), after analyzing nine commercial varieties, states that only traces of citric and malic acids are present, but that tartaric acid and acid potassium tartrate are present in considerable amount. Copper may often be detected in preserved tamarinds, derived from the boilers in which they are prepared. Its presence may be ascertained by the reddish coat which it imparts to the blade of a knife immersed in the tamarinds.

Uses.—Tamarinds are laxative and refrigerant, and infused in water form a highly grateful drink in febrile diseases. Convalescents often find the pulp a pleasant addition to their diet, and useful by preserving the bowels in a loose condition. It is sometimes prescribed in connection with other mild cathartics, and is one of the ingredients in the confection of senna. Though frequently given with infusion of senna to cover its taste, it is said to weaken its purgative power, and the same observation has been made of its influence upon the resinous cathartics in general. For a formula for *fluid-extract of tamarind*, see *Nat. Drug.*, 1892, 101.

Dose, from a drachm to an ounce (3.9 to 31 Gm.).

Off. Prep.—*Confectio Sennæ*, U. S., Br.

TARAXACUM. U. S. (Br.)

TARAXACUM [Dandelion]

(tă-răx'ă-cûm)

"The dried root of *Taraxacum officinale* Weber (Syn. *Taraxacum Taraxacum* (Linné) Karsten) (Fam. *Compositæ*), collected in autumn." U. S. "The fresh and the dried roots of *Taraxacum officinale*, *Wiggers*. Collected in the autumn." Br.

Taraxaci Radix, Br.: Dandelion Root, Blowball, Milk, Witche, or Yellow Gowan, Lion's-tooth, Cankerwort; Pissenlit, Dent de Lion, Fr. *Cod.*; *Radix Taraxaci* cum herba, P. G.; Löwenzahn, G.; Tarasaco, It.; Taraxacon, Diente de Leon, Sp.

The proper botanical name of the dandelion is not that warranted by the pharmacopœias, but is *Taraxacum Taraxacum* (L), Karst., *Deutsch Fl.* (1880-83).—*Leontodon Taraxacum*, L., *Sp. Pl.* (1753).—*T. officinale*, Weber, *Prim. Pl. Holst.* (1780).—*T. Dens-leonis*, Desf., *Fl. Atlant.* (1800).—The dandelion is an herbaceous plant, with a perennial fusiform root. The leaves, which spring immediately from the root, are long, pinnatifid, generally runcinate, with the divisions toothed, smooth, and of a fine green color. The common name of the plant was derived from the fancied resemblance of its leaves to the teeth of a lion. The flower-stem rises from the midst of the leaves, six inches or more in height. It is erect, simple, naked, smooth, hollow, fragile, and terminated by a large golden-colored flower, which closes in the evening and expands with the returning light of the sun. The involucre is smooth and double, with the outer scales bent downward. The florets are very numerous, ligulate, and toothed at their extremities. The receptacle is flat and naked. The pappus is stipitate, and at the period of maturity is disposed in a spherical form, and is so light and feathery as to be easily borne away by the wind, with the achene attached. Another plant resembling the common dandelion, the achenes of which, however, are narrower and bright red or reddish brown, known as the *red-seeded dandelion*, is the product of *T. erythrospermum*, Andr., and is supposed by some to be naturalized from Europe.

This species of *Taraxacum* grows spontaneously in widely separated parts of the globe. It is abundant in this country, adorning our grass plots and pasture grounds with its bright yellow flowers, which, in moist places, show themselves with the first opening of spring and continue to appear until near the close of summer. In India the plant is cultivated in various parts of the country, and its root collected for use between the months of September and February. (P. J., Dec. 1871, 523.) All parts of the plant contain a milky bitterish juice, which exudes when they are broken or wounded. The leaves, when very young and blanched by the absence of light during their growth, are tender and not unpleasant to

the taste, and are sometimes used as a salad. When older and of their natural color, they are medicinal. The Pharmacopœias recognize only the root, which is by far the most efficacious part. It should be full grown when collected, and should be employed in the recent state, as it is then most active. It does not, however, as stated by Duncan, lose nearly all its bitterness by drying, and the root dug up in the warmer seasons might, if dried with care, be employed with propriety in the succeeding winter. The juice of the root is thin and watery in the spring; milky, bitter, and spontaneously coagulable in the latter part of summer and autumn, and sweet and less bitter in the winter when affected by the frost. The months of July, August, and September are, therefore, the proper periods for collecting it.

Henry Barton of Brighton, England, prepared the juice from the flower-stalks by crushing and pressure, adding 25 per cent. of spirit, and, after allowing it to stand for some weeks in glass bottles, filtering to separate a very small quantity of deposit, and setting aside for use. According to Barton, it remains bright, and retains its characteristic taste. Though not so rich in solid constituents as the juice of the root, yet, having an equal bitterness, it is probably not less efficacious as a medicine, if it be true, as stated by Bentley, that the efficacy of the medicine does not depend solely on the amount of its solid constituents, but principally if not entirely on the bitter principle it contains. Barton stated that the juice is certainly one of the best preparations of taraxacum. (*A. J. P.*, 1872, p. 509.)

The fresh full grown root of the dandelion is several inches in length, as thick as the little finger or thicker, round and tapering, somewhat branched, of a light brown color externally, whitish within, having a yellowish ligneous cord running through its centre, and abounding in a milky juice. In the dried state it is dark brown, much shrunken, wrinkled longitudinally, brittle, and when broken presents a shining somewhat resinous fracture. A transverse section exhibits an exterior cortical portion, thick, spongy, whitish, and marked with concentric rings, and a smaller central portion, ligneous and yellow, though in very old roots the latter is sometimes wanting. "Cylindrical and tapering very gradually, of variable length, and 1 to 2 Cm. thick above, crowned with several short, thickish heads, usually simple or somewhat branched, the branches closely parallel; externally blackish-brown, longitudinally wrinkled; fracture short, showing a yellowish, porous central axis, surrounded by a thick, whitish bark, containing numerous milk vessels arranged in concentric circles; inodorous; bitter." U. S. *Taraxacum* should be free from the root of *Cichorium Intybus*, Linné, which closely resembles it, but is usually paler, more bitter, and has the milk vessels in radiating lines. Contrary to the general statement, that taraxacum root contains a central wood-

cylinder without any pith, Jos. Schrenk states that he has found a distinct pith in a very large number of roots taken from commercial samples of taraxacum. From ten to fifteen fibro-vascular bundles surrounded by parenchyma-tissue include the pith, the diameter of which in some instances exceeds the thickness of the woody zone several times. In other respects the structure of the root was normal, the concentric arrangement of the laticiferous ducts in particular excluding any possibility of mistaking the specimens for chicory, etc. (*Am. Drug.*, 1887, p. 2.) Its active properties are yielded to water by boiling, and do not appear to be injured in the process. Dragendorff obtained from the root gathered in October and dried at 100° C. (212° F.) 24 per cent. of *inulin* and some sugar. The root gathered in March from the same place yielded 1.74 per cent. of *inulin*, 17 of uncrystallizable sugar, and 18.7 of *levulin*. This last-named substance, discovered by Dragendorff, has the same composition as *inulin*, but dissolves in cold water, and is devoid of any rotatory power. Mannite, which has been found in the infusion of the root, has been demonstrated by Smith of Edinburgh, not to pre-exist in the root, but to be formed by spontaneous changes consequent on exposure.

A crystallizable principle has been extracted from the juice of the root by Pollex, who has named it *taraxacin*. It is bitter and somewhat acrid, fusible but not volatile, sparingly soluble in cold water, but very soluble in boiling water, alcohol, and ether. It is obtained by boiling the milky juice in distilled water, filtering the concentrated liquor, and allowing it to evaporate spontaneously in a warm place. The *taraxacin* crystallizes, and may be purified by repeated solution and crystallization in alcohol or water. Kromayer (*A. Pharm.* (2), cv. 6) also obtained *taraxacin*, and, in addition, a second crystalline principle, *taraxacerin*, $C_8H_{16}O$, insoluble in water, but soluble in alcohol. According to Vogel, the intra-cellular substance of the root consists chiefly of pectose, which is the result of a metamorphosis of the substance constituting the membrane of the cells. L. E. Sayre found that the yield of *taraxacin* varies in roots collected at different seasons. (See *Proc. A. Ph. A.*, 1893, 1894, 1895, 1896, 1897.)

The roots of various plants have been largely substituted for dandelion in England and on the Continent by the herb gatherers, and we are informed that fraudulent substitution is not unfrequent, in this country, of the root of *Cichorium Intybus*, or *chicory*. It is rare to find *chicory* mixed with dandelion, the former being usually boldly substituted for the latter.

Uses.—Taraxacum is slightly tonic, diuretic, and aperient, and is thought to have a specific action upon the liver, exciting it when languid to secretion, and resolving its chronic engorgements. It has been much employed in Ger-

many, and is a popular remedy with many practitioners in this country. The diseases to which it appears to be especially applicable are those connected with derangement of the hepatic apparatus and of the digestive organs generally. George B. Wood had confidence in it in the treatment of *chronic congestion and inflammation of the liver and spleen*, provided that there was no irritation or inflammation of the gastro-intestinal mucous membrane. He was accustomed to combine with it potassium bitartrate and aromatics when an aperient effect was desired. The dried root is sometimes mixed, in powder, with ground coffee, the taste of which covers that of the dandelion. It is also used as a substitute for coffee, being roasted and powdered and then prepared in the same manner.

Dose, one to three drachms (3.9 to 11.6 Gm.).

Off. Prep.—Fluidextractum Taraxaci, U. S. (Br.); Extractum Taraxaci, U. S., Br.; Succus Taraxaci, Br.

TEREBENUM. U. S., Br.

TEREBENE

(têr-ê-bê'nûm)

$C_{10}H_{16} = 135.10$

"A liquid consisting of dipentene and other hydrocarbons, obtained by the action of concentrated sulphuric acid on oil of turpentine and subsequent rectification with steam. Terebene should be kept in well-stoppered bottles, in a cool place, protected from light." U. S. "A mixture of dipentene and other hydrocarbons, obtained by agitating oil of turpentine with successive quantities of sulphuric acid until it no longer rotates the plane of a ray of polarized light, and then distilling in a current of steam." Br.

Térébène, Fr.; Tereben, G.

This is a substance which is produced by the action of sulphuric acid upon oil of turpentine. The sulphuric acid must be added gradually to the cooled oil of turpentine, in the proportion of one part of acid to twenty parts of oil, and after a day's standing the mixture is heated to boiling. After cooling, the oily layer is removed, freed from acid by calcium carbonate, and rectified. The terebene so obtained boils at 156° C., is optically inactive and of rather pleasant odor. Some cymol is always produced at the same time, and by continued action of the acid the terebene is said to be entirely converted into cymol and colophene. Jayne and Chase, however, from a study of a number of samples of commercial terebenes (*A. J. P.*, 1887, p. 65), conclude that the boiling point of the true terebene is much higher, 173° to 180° C. They found an inactive camphor, boiling at about 200° C. (probably *borneol*), to be formed also, and the residue left on rectifying was principally *colophene*.

Properties.—Terebene is officially described as "a colorless, thin liquid, having a rather agreeable, thyme-like odor, and an aromatic, somewhat terebinthinate taste. Specific gravity: about 0.850 at 25° C. (77° F.). Only slightly soluble in water, but soluble in three times its volume of alcohol. It boils at 155° to 165° C. (311° to 329° F.). On exposure to light and air, Terebene gradually becomes resinified, and acquires an acid reaction. Terebene should possess its characteristic agreeable odor, should not redden moistened blue litmus paper (absence of acids), and should be completely inactive toward polarized light (absence of unaltered oil of turpentine). If about 10 Cc. of Terebene be evaporated in a porcelain dish, on a water-bath, not more than a very slight residue should be left (absence of more than traces of resinous substances)." U. S. "A colorless liquid, having an agreeable odor and an aromatic terebinthinate taste. Specific gravity 0.862 to 0.866. Does not rotate the plane of a ray of polarized light. Should distil between 312.8° and 356° F. (156° and 180° C.), leaving only a slight viscid residue (absence of excess of resin). Not more than 15 per cent. should distil below 329° F. (165° C.)." Br. Power and Kleber (*Ph. Rund.*, 1894, 18) stated that pinene is not obtained by the action of sulphuric acid on oil of turpentine, that the U. S. P. 1890 boiling points 156° to 160° C. should be 170° to 185° C., and that the sp. gr. should be 0.855 instead of 0.862; also that terebene consists mainly of *dipentene* and *terpinene* with some *cymol* and *camphene*.

Uses.—Terebene is a valuable stimulant expectorant, first recommended by William Murrell (*B. M. J.*, Dec. 1885), in that form of *chronic bronchitis* often known as *winter cough*. It is very useful not only in cases of chronic bronchitis, but also in the *acute* disease, after the earlier stages have passed by. It is nearly equivalent to the oil of eucalyptus, but is a little more stimulating. It probably exerts upon other mucous membranes the same action that it does upon that of the lungs, and it has been employed with asserted good results in *dyspepsia*, especially in the flatulent intestinal variety, and may be used in chronic or subacute inflammation of the genito-urinary tract. Its action upon the general system has not been investigated, but probably resembles that of oil of turpentine. It may be given in emulsion, or, preferably, in capsules. From twenty to sixty minims (1.3 to 3.75 Cc.) of it may be given to the adult in the course of twenty-four hours, and increased, if necessary. It has been used by atomization, with asserted good results. Murrell (*B. M. J.*, July, 24, 1884) states that terebene is an active antiseptic and germicide, one part in four hundred and fifty being able to keep in check the action of the yeast plant, and one part in five hundred having a very perceptible influence on the development of bacilli and paramœcia.

Dose, three to ten minims (0.2 to 0.6 Cc.).

CANADA TURPENTINE [Canada Balsam, Balsam of Fir]

(têr-ê-bin'thî-nâ cân-â-dên'sis)

"A liquid oleoresin obtained from *Abies balsamea* (Linné) Miller (Fam. *Coniferae*)." U. S. "The oleoresin obtained from *Abies balsamea*, *Mill.*" Br.

Balsamum Canadense; Baume du Canada, Fr. Cod.; Térébenthine du Canada, Fr.; Canadischer Terpentín, G.

The term *turpentine* is usually applied to certain vegetable juices, liquid or concrete, which consist of resin combined with a peculiar essential oil, called *oil of turpentine*. They are generally procured from different species of pine, fir, or larch, though other trees afford products which are known by the same general title, as, for instance, *Pistacia Terebinthus*, which yields the Chian turpentine. Some French writers extend the name of turpentine to other juices consisting of resin and essential oil, without benzoic or cinnamic acid, as copaiba, balm of Gilead, etc. We shall describe particularly, in this place, the turpentine which are either now official or have but recently ceased to be so. A brief botanical view of the plants from which they are respectively derived will be in accordance with the plan of this work. It is proper to observe first that the family *Coniferae* includes about three hundred and fifty species. These may be divided into two sub-orders, as Engler and Prantl suggest,—viz., *Pinoideæ* and *Taxoideæ*. Lindley had previously recommended a similar subdivision, but considered each sub-group as deserving of family rank, and gave them the names *Pinaceæ* and *Taxaceæ*. Britton and Brown, in their *Illustrated Flora of the U. S. and Canada*, follow Lindley in this instance. The *Pinoideæ* may be further subdivided into the (A) *Abietineæ*, including *Araucaria*, *Pinus*, *Cedrus*, *Larix*, *Picea*, *Tsuga*, *Abies*, *Sequoia*,

Taxodium, etc.; and (B) *Cupressineæ*, which include Thuja, Juniperus, etc. The *Taxoideæ* include Ginkgo, Taxus, etc.

The genus *Pinus* is represented by about seventy species, which are widely distributed throughout the northern hemisphere of both continents. The principal centres of distribution of the species of this genus are in the Western United States (twenty-five species), Eastern United States (thirteen species), and the highlands of Mexico. It is one of the most important genera from an economic standpoint. The following species yield valuable timber: *P. palustris*, *P. Strobus*, *P. echinata*, *P. lambertiana*, *P. ponderosa*, *P. monticola*, *P. heterophylla*, *P. sylvestris*, *P. Laricio*, *P. nelsonii*, *P. Thunbergii*, and *P. densiflora*. Turpentine is obtained chiefly from the Eastern American *P. palustris* and *P. heterophylla*; it is also obtained from *P. Pinaster* and *P. halepensis* of the Mediterranean basin, and from the Himalayan *P. Roxburghii*. The edible seeds (*Pine Nuts*) of several species yield important articles of human food, the best being produced by the nut pines of Western North America, by *P. pinea* of the Mediterranean, *P. Cembra* of Europe and Asia, and *P. gerardiana* of North-western India. *Pine wool*, a coarse fibre manufactured from the leaves of *P. Laricio*, *P. sylvestris*, and other European species, is used to stuff mattresses and cushions, and, woven with animal wool, is made into hospital and military blankets and into underclothing which are reputed to possess medicinal properties. In the Southern United States carpets are woven from the leaves of *P. palustris*. The bark of several species contains sufficient tannin to make them valuable for tanning leather.

1.—*Pinus palustris*, Mill., *Gard. Dict.* (1768) 8th ed., No. 14.—*P. australis*, Michx. f., *Hist. Arb. Am.* (1810) i. 64.—Leaves in threes, from ten to fifteen inches long, subtended at the base by a conspicuous scaly sheath from one to one and a half inches long. The leaves are crowded at the ends of the branches. The cones are terminal, conical, and armed with a short recurved spine.

This is a very large indigenous tree, growing in dry, sandy soils, from the southern part of Virginia to the Gulf of Mexico. Its mean elevation is sixty or seventy feet, and the diameter of its trunk about fifteen or eighteen inches for two-thirds of its height. The leaves are about a foot in length, of a brilliant green color, and united in bunches at the ends of the branches. The names by which the tree is known in the Southern States are *long-leaved pine*, *yellow pine*, *Southern pine*, *hard pine*, *Virginia pine*, and *pitch pine*; but the first is the most appropriate. This tree furnishes by far the greater proportion of the turpentine, tar, etc., consumed in or exported from the United States. (See *Pice Liquida*.)

2.—*Pinus Teda*, L., *Sp. Pl.* (1753) 1000; Willd., *Sp. Plant.* iv. 498; Michaux, *N. Am. Sylva*, iii. 156; B. & T. 259.—“Leaves in threes,

elongated with elongated sheaths; strobiles oblong-conical, deflexed, shorter than the leaf; spines inflexed.”

This is the *loblolly* or *old field pine* of the Southern States. It is abundant in Virginia, where it occupies the lands exhausted by cultivation. It exceeds eighty feet in height, has a trunk two or three feet in diameter, and expands into a wide spreading top. The leaves are about six inches long, and of a light green color. It yields turpentine in abundance, but less fluid than that which flows from the preceding species.

3.—*Pinus sylvestris*, L., *Sp. Pl.* (1753) 1000; Willd., *Sp. Plant.* iv. 494; Michaux, *N. Am. Sylva*, iii. 125; B. & T. 257. *Scotch Pine*, *Norway Pine*, *Scotch Fir*.—Leaves in pairs, rigid; strobiles ovate-conical, of the length of the leaves; scales linear-oblong, the ends much thickened, their exposed parts (apophysis) oblique, rhomboidal, with a transverse ridge and central tubercle.

This tree, when of full size, is eighty feet high, with a trunk four or five feet in diameter. It inhabits Scotland and the northern and mountainous parts of Europe. It yields a considerable proportion of the common European turpentine.

4.—*Pinus Pumilio*, Haenke, Jviasek, *Beob. Riesengeb.* (1791) 68.—*P. montana*, Mill., *Gard. Dict.*, 8th ed., No. 5.—This pine is known in gardens under several names which are given to the forms occurring in the different mountain ranges over which it is spread. Beissner, in his *Handbuch der Nadelkolkzunde*, considers *P. Pumilio*, Haenke, a synonym of *P. montana*, Mill., whereas in the *Index Kewensis* the latter is brought under the former. Most authors agree with De Candolle and Beissner in bringing *P. Pumilio*, Haenke, under *P. montana*, Mill. The latter is a small tree, with decumbent or knee-like more or less erect branches, which are covered with a dark colored persistent bark. The leaves occur two in a sheath, each of which is from two to five Cm. long, straight, or scythe-shaped, with obtuse apex; both sides are dull green and slightly glaucous. The cones are ovoid, about one and a half inches long, with a pyramidal protuberance on each scale on the outer or exposed side. It is found in the sub-alpine regions of Central Europe at elevations between 4000 and 8000 feet; also on the Carpathian Mountains at from 4000 to 5500 feet. From its branches by spontaneous exudation or by cutting off their ends, Hungarian balsam is obtained.

Pinus Pinaster, Salander (*P. maritima*, Poir.), which is found in the southern and maritime parts of Europe, yields much of the turpentine, pitch, and tar consumed in France, and is admitted among the official plants in the French Codex. *Pinus lambertiana* of California, produces by exudation a saccharine matter which has been found to contain a peculiar sweet principle called *pimate*. (*C. R. A. S.*, Sept. 1855.) *Pinus sabiniana*,

Dougl., known as *nut-pine* or *digger-pine* (because the nut is largely consumed by the Digger Indians), yields, on being notched, a turpentine whose volatile oil is extensively used in California under the name of *abietene*. (See page 879.) The *Pinus rigida*, or *pitch pine* of this country, and probably others besides those mentioned, are sometimes employed in the preparation of tar. *Pinus Teocott* yields a turpentine known as Mexican or Brea turpentine, which is used in Mexico.

ABIES.—The genus *Abies* is represented by about twenty-three species, which are distributed in the New World from Labrador and the valley of the Athabasca River to the mountains of North Carolina and from the mountains of Alaska to the highlands of Guatemala, and in the Old World from Siberia and the mountains of Central Europe to Southern Japan, the Himalayas, Asia Minor, and the mountains of Northern Africa. The species of this genus yield soft, perishable woods and balsamic exudations, which are employed in medicine and the arts.

Abies balsamea, Mill., *Gard. Dict.* (1768) 8th ed., No. 3; Lindley, *Flor. Med.* 554.—*A. balsamifera*, Michaux, *N. Am. Sylva*, iii. 191.—*Pinus balsamea*, L., *Sp. Pl.* (1753) 1002; Willd., *Sp. Plant.* iv. 504.—“Leaves solitary, flat, emarginate or entire, glaucous beneath, somewhat pectinate, sub-erect above, recurved spreading; cones cylindrical, erect; bracts abbreviate, obovate, conspicuously mucronate, sub-serrulate.”

This is the *American silver fir*, or *balm of Gilead tree*, inhabiting Canada, Nova Scotia, Maine, and the mountainous regions farther south. It is an elegant tree, seldom rising more than forty feet, with a tapering trunk, and numerous branches, which diminish in length in proportion to their height and form an almost perfect cone. The leaves are six or eight lines long, inserted in rows on the sides and tops of the branches, narrow, flat, rigid, bright green on their upper surface, and of a silvery whiteness beneath. The cones are large, erect, nearly cylindrical, of a purplish color, and covered with a resinous exudation, which gives them a glossy, rich, and beautiful appearance. It is from this tree that the *Canada balsam* is obtained.

Several other species of *Abies* are official. The *A. Picea* (*Abies pectinata* of De Candolle, *Pinus picea* of Linnæus), or *European silver fir*, growing in the mountainous regions of Switzerland, Germany, and Siberia, yields the *Strassburg turpentine* (*Térébentine d'Alsace* or *des Vosges*), which is much used in some parts of Europe. By the distillation of its cones with water it also affords a variety of oil of turpentine called in France *essence de tempine*. By boiling the young branches of the allied *Picea Mariana* (Mill.), B. S. P. (*Pinus nigra*, Ait., *Abies nigra*, Desf.), or *black spruce* of this country, and evaporating the decoction, the *essence of spruce* is prepared. It is a thick,

molasses-like liquid, with a bitterish, acidulous, astringent taste, and is used for making *spruce beer*.¹

Abies Fraseri, Lindley.—This species, commonly called *double fir*, occurs at high elevations in the mountains of Tennessee and North Carolina. The tree is noted for its hardness, and is used for ornamental purposes. It is also said to have been used to furnish a balsam of fir similar to that obtained from *A. balsamea*, but the data concerning this are obscure.

Russian White Pitch, “belji var,” “Sos nowaja Smold,” probably derived from the Siberian Fir, *Abies Pichta*, Forb. (*Picea obovata*, Ledeb.), contains, according to A. Tschireh, two free resin acids, the amorphous, *beljiabieninic acid*, $C_{13}H_{20}O_2$, and the crystalline, *beljiabietinic acid* besides *beljiresene*, $C_{18}H_{26}O$ and an essential oil. (*A. Pharm.*, Nov. 1902.)

LARIX.—The genus *Larix* has eight recognized species, which are now widely distributed over the sub-arctic and mountainous regions of the northern hemisphere, ranging from the Arctic Circle to the mountains of Pennsylvania in the New World and to latitude 30° in the Old World. The species produce hard, durable, valuable timber; turpentine, which is sometimes used in medicine; tar; bark rich in tannin; and a peculiar manna-like substance.

Larix Larix (L.), Kaerst.; *Pinus Larix*, L., *Sp. Pl.* (1753) 1001; Willd., *Sp. Plant.* iv. 503; Woodv., *Med. Bot.* 7, t. 4.—*Larix europæa*, De Cand., *Flor. Fr.* 2064.—*Abies Larix*, Lamb., *Illustr.* t. 785, f. 2.—“Leaves fascicled, deciduous; cones ovate-oblong; margins of the scales reflexed, lacerated; bracts panduriform.” The *European larch* is a large tree inhabiting the mountains of Siberia, Switzerland, Germany, and the east of France. It yields the *Venice turpentine* of commerce, and a peculiar sweetish substance called in France *Briançon manna*, which exudes spontaneously and concretes upon its bark. When the larch forests of Russia take fire, a juice exudes from the trunk during their combustion, which concretes and is called *Orenburg gum*. It is wholly soluble in water.²

¹ The following is the formula: Take of essence of spruce half a pint; pimenta bruised, ginger bruised, hops, each, four ounces; water three gallons. Boil for five or ten minutes; then strain, and add of warm water eleven gallons; yeast a pint; molasses six pints. Mix, and allow the mixture to ferment for twenty-four hours.

² *Confierin*.—This name has been given to a principle discovered by Hartig in the cambium of several of the Conifers. The species in which it has been found are *Pinus Strobus* and *P. Oembra*, *Picea Abies* and *A. pectinata*, and *Larix Larix*, and it probably exists in many others. It is obtained by removing the outer bark, scraping the cambium from the surface of the wood, subjecting this to pressure, boiling the viscid juice to coagulate the albumen, filtering, and evaporating the filtered liquid to one-fifth of its volume. The confierin is deposited in crystals. The mother-water is very sweet, and contains a saccharine substance closely allied to cane sugar. The crystals are purified by dissolving them in water, decolorizing by animal charcoal, and finally crystallizing from weak alcohol. Confierin was chemically examined by M. W. Kubel, and later by Tiemann and Haarmann, who proved that it is a glucoside and as crystallized from the juice has the composition $C_{16}H_{22}O_8 + 2H_2O$. When treated with dilute acids

In Japan, the exudation from the *Pinus densiflora* and that from the *Pinus Thunbergii* are used under the respective names of *akamatsu* and *kuromatsu*. They are said to contain about 18 per cent. of oil and 81 per cent. of resin. The distilled oil is bright and colorless, having an odor somewhat different from that of the European oil of turpentine. It boils at from 155° to 156° C., and has a specific gravity of a little under 0.87. Its index of polarization is from 55° to 61° (dextrogyrate). The resin cannot be distinguished from the European. A turpentine closely resembling the French oil is produced in Burmah from the *Pinus Khasya* and *Pinus Merkusii*. (See *P. J.*, lvi. 1896, 370.)

PISTACIA.—See *Mastiche*.

Pistacia Terebinthus, L., *Sp. Pl.* (1753) 1025; Willd., *Sp. Plant.* iv. 752; Woodv., *Med. Bot.* 29, t. 12.—This is a small tree of the family Anacardiaceæ, with numerous spreading branches, bearing alternate, pinnate leaves, which consist of three or four pairs of ovate-lanceolate, entire, acute, smooth, and shining leaflets, with an odd one at the end. The male and female flowers are diceious, small, and in branching racemes. It is a native of Barbary and Greece, and flourishes in the islands of Cyprus and Chio, the latter of which has given its name to the *Chian turpentine* obtained from the tree. A gall produced upon this plant by the puncture of an insect has been used in Eastern Europe in pectoral affections.

We shall treat of the several varieties of turpentine under distinct heads.

1. WHITE TURPENTINE.

Terebinthina, U. S.; Thus Americanum, Br.; Common Frankincense; Térébenthine de Boston, Fr.

In former times, large quantities were collected in New England, but the turpentine trees of that section of the Union have long been entirely exhausted, and our commerce has been until recently almost exclusively supplied from North Carolina and the southeastern parts of Virginia. Latterly attention was turned to the collection of this valuable product in Georgia and Florida, and now an abundant supply is derived from the vast pine forests which occupy the southern portion of our country bordering on the Gulf of Mexico.

During the winter, deep notches or excavations of the capacity of about three pints are made in the trunk of the tree three or four inches from the ground, and for about three feet above these so-called "boxes" the tree is deprived of its bark and some of the wood scraped off. Into these the juice or "crude" begins to flow about the middle of March, and continues to flow throughout the warm season, slowly at first,

rapidly in the middle of summer, and more slowly again in the autumn, the tree being scraped every eight or ten days to prevent clogging. The liquid is removed from the "boxes" as they fill, and transferred into casks, where, if left, it gradually thickens, and ultimately acquires a soft solid consistence, but most of it is separated at once by distillation into the rosin and the volatile oil.

White turpentine, as found in commerce, is yellowish white, of a peculiar somewhat aromatic odor, and a warm, pungent, bitterish taste. It is somewhat translucent, and of a consistence varying with the temperature. In the middle of summer it is almost semi-fluid and very adhesive; though brittle in the winter it is often so firm and hard as to be incapable of being made into pills without heat. "In yellowish, opaque masses, brittle in the cold; lighter internally, sticky and more or less glossy; odor and taste terebinthinate. The alcoholic solution of Turpentine has an acid reaction." *U. S.* Exposed to the air it ultimately becomes perfectly hard and dry. In the recent state it affords about 17 per cent. of volatile oil. It is likely to contain small pieces of bark, wood, or other impurity. Tschirch and Koritschoner found the following constituents in white turpentine: *palabienimic acid*, $C_{13}H_{20}O_2$, 5 per cent.; *palabietinic acid*, $C_{20}H_{30}O_2$, which is crystalline, 6 to 7 per cent.; α - and β -*palabietinolic acids*, together 53 to 57 per cent. Both the latter are amorphous and are separated by the differing solubility of their lead salts. All the acids are soluble in sodium hydroxide solution. The portion of the resin insoluble in NaOH solution consists of essential oil, 20 to 22 per cent., and *paloresene*, 10 per cent., with traces of a bitter principle. The essential oil has a characteristic turpentine-like odor. The sp. gr. is 0.864. It is dextrogyrate, while the resin itself and palabietinic acid are lævogyrate. The authors have furthermore examined *Russian white pitch*, a product known as "belji var," and probably derived from the Siberian fir. (*A. Pharm.*, Nov. 1902.)

2. COMMON EUROPEAN TURPENTINE.

Térébenthine de Bordeaux, Fr. Cod.; Térébenthine commune, Fr.; Gemeiner Terpentin, G.; Trementina comune, It.; Trementina comun, Sp.

This is the *Terebinthina vulgaris* of the former London Pharmacopœia. It is furnished by several species of pine, but chiefly by *P. sylvestris* and *P. Pinaster*. From the latter tree it is obtained largely in the maritime districts of the southwest of France, especially in the department of the Landes, and is exported from Bordeaux. Hence it is called in commerce *Bordeaux turpentine*. It is procured by making incisions into the trunk, or removing portions of the bark, and receiving the juice which flows out, in small troughs, or in holes dug at the foot of the tree. It is purified by heating, and filtering it through straw, or by exposing it to the sun in a barrel, through holes in the bottom of

or ferments it is decomposed as follows: $C_{16}H_{22}O_8 + H_2O = C_8H_{12}O_4 + C_8H_{12}O_4$. When this latter compound is oxidized (or coniferin itself) by potassium dichromate and sulphuric acid, *vanillin* is obtained, $C_8H_8(OH) \begin{cases} OCH_3 \\ CHO \end{cases}$. Vanillin has been thus made commercially, but is now made preferably from the eugenol of oil of cloves or from benzoin.

which the melted turpentine escapes. Thus prepared, it is whitish, turbid, thickish, and separates, upon standing, into two parts, one liquid and transparent, the other of a consistence and appearance like that of thickened honey. As found in European commerce, it often consists wholly of this latter portion. It speedily hardens on exposure in thin layers to the air. The most liquid specimens are completely solidified by the addition of one part of magnesia to thirty-two parts of the turpentine. (*J. P. C.*, xxv. 499.) It is scarcely ever given internally, but furnishes large quantities of oil of turpentine and rosin. We do not import it into this country. The substance which the French call *galipot*, or *barras*, is that portion of the turpentine which concretes upon the trunk of the tree when wounded, and is removed during the winter. (Thénard.) This, when purified by melting with water and straining, takes the name of *yellow or white pitch*, or *Burgundy pitch*. When turpentine, whether the European or the American, has been deprived of its oil by distillation, the resin which remains is called *rosin*, and sometimes *colophony*, from the Ionian city of Colophon, where it was formerly prepared. It is the official rosin (*resina*), and is sometimes called *yellow rosin* (*resina flava*). White rosin (*resina alba*) is prepared by incorporating this, while in fusion, with a certain proportion of water. (See *Resina*.) Tar (*pix liquida*) is the product extracted from the wood by slow combustion and chemically altered by heat. Common pitch (*pix nigra*, or *resina nigra*) is the solid residue left after the evaporation by boiling of the liquid parts of tar.

3. CANADA TURPENTINE.

Baume du Canada, *Fr. Od.*; Canadischer Balsam, Canadischer Terpentlin, *G.*; Trementina del Canada, *It.*

Terebinthina Canadensis, U. S., Br., is collected in Canada and the State of Maine from the *Abies balsamea*, by breaking the vesicles which naturally form upon the trunk and branches, and receiving their liquid contents in a bottle. "Viscid, pale yellowish or greenish-yellow, transparent; odor agreeable; taste terebinthinate, bitter, and slightly acrid. When exposed to the air, Canada Turpentine gradually dries and forms a transparent varnish; it solidifies on being mixed with 20 percent. of its weight of magnesium oxide previously moistened with water; it is completely soluble in ether, chloroform, or benzene." *U. S.* "Solidifying when mixed with about a sixth of its weight of *magnesia* moistened with a little water." *Br.* For a paper on its miscibility in alcohol, by J. E. Morrison, see *Proc. A. Ph. A.*, 1894, 309. By time and exposure it becomes thicker and more yellow, and finally solid. It is usually brought into market in bottles under the name of *Canada balsam* or *balsam of fir*. Under the microscope the hard balsam is found to be entirely free from any granular or crystalline structure. In Europe it is sometimes called *balm of Gilead*, from its supposed resemblance to that

celebrated medicine. The term *balsam*, as at present understood, is improperly applied to it, as it contains no benzoic or cinnamic acid, and is in fact a true turpentine, consisting chiefly of resin and volatile oil. Bonastre obtained from 100 parts of Canada turpentine 18.6 parts of volatile oil, 40.0 of resin easily dissolved by alcohol, 33.4 of sub-resin of difficult solubility in that fluid, 4.0 of caoutchouc similar to sub-resin, and 4.9 of bitter extractive and salts, besides traces of acetic acid. Flückiger found in 100 parts 24 parts of an essential oil, $C_{10}H_{16}$, with a very small proportion of an oxygenated oil, 60 parts of a resin soluble in boiling alcohol, and 16 parts of a resin soluble only in ether. (*Pharmacographia*, 2d ed., 614.) Emmerich obtained by fractional distillation of the oil *bornyl* or *terpinyl acetate*, *pinene*, and a fragrant liquid resembling oil of lemon. (*A. J. P.*, 1895, 135. See also a paper by Hunkel, *A. J. P.*, 1895, 9.) The chief distinction between it and *Strassburg turpentine*, which is sometimes sold for it in commerce, is in the diverse odors.

According to Tschirch, Weigel and Bruening, Canada turpentine contains about 63 per cent. of acid resins, from 23 to 24 per cent. of volatile oil, and from 11 to 12 per cent. of indifferent resin. The acid portion consists of four acids, of which one—*canadonic acid*, $C_{19}H_{34}O_2$ —obtained by treating the oleoresin with ammonium carbonate, with which it combines; a small amount of crystalline *canadolic acid*, $C_{19}H_{32}O_2$, and two amorphous isomeric acids—*α*- and *β*-*canadinolic acids*, $C_{19}H_{30}O_2$ —which constitute the main portion of the acid resins. The indifferent resin has the formula $C_{21}H_{40}O$. The greater part of the volatile oil boils between 160° C. and 167° C. (*A. Pharm.*, 1900, Aug. and Sept., 401, 411 and 487.)

Abies Menziesii, Lind.—From this, a *Balsam of Fir* of the Pacific Slope, has been obtained; it is a turpentine similar to Canada balsam, but it is, however, scarcely a commercial article.

4. VENICE TURPENTINE.

Térébenthine de Venise, *Fr. Od.*; Térébenthine de Mèlze, *Fr.*; Venetianischer Terpentlin, *G.*; Trementina di Venezia, *It.*; Trementina de alerce, Trementina de Venecia, *Sp.*

This turpentine was named from the circumstance that it was formerly an extensive article of Venetian commerce. It is procured in Switzerland, and in the French province of Dauphiny, from the *Larix europæa*,¹ or larch,

¹ Tschirch and Weigel investigated the constituents of *Larch Turpentine*—which is the oleoresin from *Larix Laricina*; it contains from 60 to 64 per cent. of acid resins soluble in soda, from 20 to 22 per cent. of volatile oil, and from 14 to 15 per cent. of indifferent resin. The acid resins consist mainly of two isomeric amorphous bodies *α*- and *β*-*larinolic acid*, $C_{20}H_{36}O_2$, and a smaller quantity of the crystalline *larinolic acid*, $C_{20}H_{34}O_2$. The greater portion of the volatile oil boils between 155° and 170°; a smaller quantity of higher boiling sesquiterpene commencing to boil at 190° C. The recently distilled oil has the sp. gr. 0.872, and possesses a characteristic turpentine odor. It is soluble in all proportions in alcohol and other solvents. (*A. Pharm.*, 1900, Aug. and Sept., 401, 411, 487.)

which grows abundantly upon the Alps and the Jura Mountains. The peasants bore holes into the trunk about two feet from the ground, and conduct the juice by means of wooden gutters into small tubs placed at a convenient distance. It is afterwards purified by filtration through a leather sieve. Genuine Venice turpentine is a viscid liquid, of the consistence of honey, flowing with difficulty, cloudy or imperfectly transparent, yellowish or slightly greenish, of a strong not disagreeable odor, and a warm, bitterish, and acrid taste. It does not readily concrete on exposure, is not solidified by one-sixteenth of magnesia, and is entirely soluble in alcohol. (Guibourt, *J. P. C.*, xxv. 500.) H. Beckurts and W. Brueche found the specific gravity at 15° C. from 1.060 to 1.190; acid number from 76 to 101 (Kremel found from 63 to 70.3); ester number from nothing to 6; saponification number from 81 to 101, and the iodine number from 137 to 149. (*A. Pharm.*, 1892, cccxxx. 83.) It yields on an average 15 per cent. of essential oil, of the composition $C_{10}H_{16}$, which has been found to be nearly pure *pinene*. The residual resin is soluble in two parts of warm alcohol of 75 per cent., and more copiously in absolute alcohol. What is sold under the name of Venice turpentine, in commerce, is usually quite brown, and is a factitious substance, prepared by dissolving rosin in oil of turpentine. According to G. Fabris the nature of these spurious Venice turpentines can readily be detected by dissolving 5 Gm. of the sample in 20 Cc. of 95 per cent. alcohol, adding a few drops of phenolphthalein and sufficient of a 10 per cent. solution of potassium hydroxide to render it alkaline. With genuine Venetian turpentine a clear solution is obtained, while the spurious drug yields a turbid solution, from which, on standing, drops of oily resin separate.

5. CHIAN TURPENTINE.

Térébenthine de Chio, *Fr. Cod.*; Cyprischer Terpentin, *G.*; Trementina Cipria, *It.*

This variety of turpentine is collected chiefly in the island of Chio, or Scio, from the *Pistacia Terebinthus*, and it is said that the whole annual product of the island is only about two hundred and twenty-four pounds. During the summer the juice flowing spontaneously, or from incisions in the bark, falls upon smooth stones, or bundles of twigs, placed at the foot of the tree, from which it is procured by boiling and straining. After straining it is again boiled with a little water until all the water is evaporated, when it is finally poured into a vessel of cold water and kneaded. At first it is of a dirty yellow color, but after kneading it becomes quite white. (*P. J.*, xvi. 385.) The annual product of each tree is very small, and the turpentine, therefore, commands a high price even in the place where it is procured. Very little of it reaches this country. It is said to be frequently adulterated with the other turpentines. It is a thick, tenacious liquid, of a

greenish-yellow color, or it occurs as a viscid opaque mass. The odor¹ is peculiar, penetrating, and more agreeable than that of the other substances of the same class. The taste is mild, without bitterness or acrimony. Flückiger found nearly 14½ per cent. of essential oil, which contained a small quantity of an oxygenated oil. It leaves a glutinous residue when treated with strong alcohol. (Guibourt.) Its alcoholic solution does not redden litmus paper. (Martindale.) On exposure, liquid Chian turpentine speedily thickens, and ultimately concretes into a translucent solid, yellowish or yellowish-brown when in small pieces, greenish-brown in mass.

Besides the turpentines mentioned, various others are noticed in books on *Materia Medica*, though not found in commerce in this country. There are the *Strassburg turpentine*, much used in France, and obtained from the *Abies Picea* (*Abies pectinata* of De Candolle), or European silver fir, which grows on the mountains of Switzerland and Germany and bears a close resemblance, as well in its appearance as in its product, to *Abies balsamea* of Canada; the *Russian turpentine*, from *Pinus sylvestris*;² the

¹The odor of Chian turpentine is variously described. As the only tests we now have of the purity of the drug are its physical characteristics, and of these the odor is the most important, we give the following description by Wm. Martindale. (*P. J.*, April, 1880.) Chian turpentine "has when fresh a distinctive odor, slightly like the pinaceous turpentines, but much more agreeable and aromatic, according to some resembling citron and jasmine; but there is always a background smell like that of mastic, which becomes more developed and distinct with age, when it has lost the more volatile portion, the essential oil. According to Perelra, the turpentine-like odor is combined with the odor of fennel, and Guibourt says, when kept in a covered glass vessel the odor is strong and agreeable, analogous to that of fennel or the resin of elemi. It probably loses this rapidly. A specimen, bearing Guibourt's name, in the Ph. Society's Museum, has now no trace of it, but the mastic odor is very persistent. If the fennel odor be very evident in it I should fear the sample was not genuine, as in a statement made in the *Lancet* the writer says what is sold as Chian turpentine 'is either greatly adulterated or a wholly factitious article, manufactured from black resin, Canada balsam, and the essential oils of fennel and juniper.' The taste of genuine Chian turpentine resembles that of mastic; it is agreeable and free from the characteristic bitterness and acidity of the pinaceous turpentines."

²For details as to the varieties of European turpentine and the methods of procuring them, consult *A. J. P.*, 1878, 69, 479; *Proc. A. Ph. A.*, xxiv. 203; *P. J.*, vii. 263; x. 447.

Bordeaux Turpentine.—Tschirch and Bruening find this oleoresin to have the following composition: 6 to 7 per cent. of *pinaric acid*, $C_{15}H_{24}O_2$; 8 to 10 per cent. of *pinaric acid*, $C_{15}H_{24}O_2$; 48 to 50 per cent. of *alpha- and beta-pinaric acid*, $C_{15}H_{24}O_2$; 5 to 6 per cent. of *bordoresin*, together with traces of *succinic acid*. The acid resins are soluble in sodium hydroxide solution, the pinaric acid being separable from the other two by its property of forming with ammonium carbonate a water-soluble double salt. The volatile oil consists of two fractions, the larger fraction, amounting to about 85 per cent. of the whole, distilling easily. (*A. Pharm.*, 238, Nov. 10, 1900, 630.)

Finian Turpentine, the oleoresin of *Pinus sylvestris*, is found by Tschirch and Niederstadt to consist of: 1.5 per cent. *silveolic acid*, $C_{15}H_{24}O_2$; 58 to 60 per cent. of *alpha-silveolic acid*, $C_{15}H_{24}O_2$, and *beta-silveolic acid* ($C_{15}H_{24}O_2$); 20 to 21 per cent. of *resene*; 15 per cent. of volatile oil; and traces of bitter principle and succinic acid. Silveolic acid is crystalline; *alpha- and beta-silveolic acids* are both amorphous. The volatile oil has the sp. gr. 0.840 at 15° C., is soluble in all proportions in alcohol, ether, and chloroform, and is neutral when recently distilled, but becomes acid when exposed to the air. (*A. Pharm.*, 239, April 30, 1901, 167.) (Continued on next page.)

Damara turpentine, which speedily concretes into a very hard rosin, and is derived from *Pinus Damaris*, Lam., the *Agathis damara* of Richard, growing in the East India islands; the *courie* or *cowdie* resin, procured by incision from another species of *Agathis*, *A. australis*, in New Zealand; and the *Dombeya turpentine*, a glutinous, milky-looking fluid, of a strong odor and taste, derived from the *Araucaria Dombeyi* of Richard, also called *Dombeya excelsa*, which inhabits Chili.

Tschirch and Weigel (*A. Pharm.*, 1900, Aug. and Sept., 401, 411, 487) investigated Strassburg turpentine—the oleoresin of *Abies Picea*; it contains from 8 to 10 per cent. of an acid resin, *abieninic acid*, $C_{15}H_{20}O_2$; from 1.5 to 2 per cent. of a crystalline acid resin, *abietolic acid*, $C_{20}H_{28}O_2$; from 46 to 50 per cent. of two amorphous isomeric acid resins, α - and β -*abietinolic acid*, $C_{15}H_{22}O_2$; from 12 to 16 per cent. of a neutral resin, *abieto-resin*; and from 28 to 30 per cent. of volatile oil, together with traces of succinic acid, bitter principle, coloring matter, moisture and impurities. The oil when recently distilled has the sp. gr. 0.860, boiling between 148° and 165° C.; the major fraction distills between 162° and 163° C. It has a greenish fluorescence and a lemon-like odor. When the oleoresin is distilled with potassium hydroxide a pleasant rose or orange-flower odor is developed, possibly due to the liberation of a fragrant alcohol.

Properties.—The turpentines resemble one another in odor and taste, though distinguished by shades of difference. Liquid at first, they become thick and gradually solid by exposure, in consequence partly of the volatilization, partly of the oxidation of their essential oil. They are rendered more liquid or softened by heat, and at a high temperature take fire, burning with a white flame and much smoke. Water extracts only a minute proportion of their volatile oil. They are almost wholly soluble in alcohol and ether, and readily unite with the

sylvestrene) of the formula $C_{10}H_{16}$, the residue consisting exclusively of rosin. (See *Oleum Terebinthinæ* and *Resina*.) Both the cones and leaves of *Abies Picea* yield oils known respectively as *pine cone oil* and *pine needle oil*. According to *Schimmel's Report* for April, 1897, they both contain pinene, limonene, and bornyl acetate. The oil from *Pinus sylvestris*, known as *fir oil*, also contains bornyl acetate to the amount of 12 per cent., according to *Schimmel's Report* for October, 1897, 47. On the other hand, the oil from *Larix Larix*, known as *larch needle oil*, contains 8.1 per cent. of bornyl acetate and 6.14 per cent. of free bornyl. (*Ibid.*, 61.)

Schiff affirms that the odor of turpentine is due to the presence of a product of oxidation, probably a camphoric aldehyde, $C_{10}H_{16}O_3$, which, with the odor, may be removed by shaking the turpentine with sodium bisulphite. A non-odorless turpentine may also be obtained by washing with solution of sodium hydroxide and distilling in an atmosphere of carbon dioxide. From the experiments of Faure of Bordeaux, it appears that some of the liquid turpentines, like copaiba, may be solidified by the addition of magnesia. (*Journ. de Chim. Méd.*, 1830, 94.) According to Thierry, the same result is obtained by the addition of one part of calcium hydroxide to thirty-two parts of common European turpentine (*J. P. C.*, 3e sér., i. 315.) Crouzel (*P. J.*, 1892, 11) found tannin in the bark of *P. Pinaster*, associated with a peculiar reddish-yellow coloring matter, representing tannin in the process of formation.

Ed. Hirschsohn made experiments with the object of determining a reliable method for distinguishing artificial turpentine from the common, natural turpentine and larch turpentine, this becomes possible by the difference in the solvent effect of official ammonia water and alcohol, sp. gr. 0.863 at 15.6° C. (60° F.), upon them, under the conditions indicated in the following table:

Kind of Turpentine.	Ammonia Solution (sp. gr. 0.960), 1 p. turpentine and 5 p. ammonia solution.	Alcohol (sp. gr. 0.863), 1 p. turpentine and 3 p. alcohol.
Venice turpentine	Is not disintegrated; produces a milky fluid in the water-bath.	Yields a nearly clear solution.
Common turpentine	Easily disintegrated, forming a milky mixture, then gelatinous; becomes clear in the water-bath.	Large quantities are deposited, but the mixture becomes clear in the water-bath.
Artificial turpentine	Is disintegrated, becomes clear in the water-bath for a moment, then turbid.	Turbid solution and precipitation; turbid in the water-bath with precipitation.

fixed oils. They yield by distillation a volatile oil, called *oil of turpentine*, the composition of which is essentially uniform, it being composed of several terpenes (pinene, dipentene, and

A mixture of common turpentine with larch (Venice) turpentine is recognized by the turbidity of, and precipitate from, the solution of 1 Gm. of the sample in 3 Gm. of alcohol sp. gr. 0.863. The same occurs if the common is replaced by artificial turpentine, but the latter

Jura Turpentine.—A. Tschirch and E. Bruening have determined the following constituents of the oleoresin of *Picea vulgaris*: From 2 to 3 per cent. of *picea-pimaric acid*, $C_{15}H_{20}O_2$; from 1.5 to 2 per cent. of *picea-pimaric acid*, $C_{20}H_{28}O_2$; from 48 to 50 per cent. of α - and β -*picea-pimaric acid*, $C_{15}H_{22}O_2$; from 32 to 33 per cent. of volatile oil; from 10 to 12

per cent. of resene, $C_{27}H_{40}O$; and traces of succinic acid, coloring matter and bitter principle. (*A. Pharm.*, 238, Nov. 10, 1900, 616.)

is differentiated by ammonia, from the fact that in the presence of 20 to 30 per cent. of common turpentine the sample is easily disintegrated, and the solution becomes clear in the water bath, while in the presence of artificial turpentine the behavior is the same as with the pure Venice turpentine. (*Ph. Centralh.*, Nov. 26, 1903, 825 to 828.)

Uses.—The physiological activities of turpentines depend upon their volatile oils. They are so inconvenient of administration, and so variable in their activity that at present they are very rarely, if ever, used by regular practitioners of medicine. For an account of their physiological and therapeutic properties see *Oleum Terebinthinae*, p. 877. If given at all they should be administered in emulsion. Chian turpentine has been strongly recommended as a specific in *cancer*, given in emulsion in doses of five grains (0.32 Gm.), increased *pro re nata*, and also applied locally. It is probably without value. Turpentine vapor baths have been found useful in the treatment of *chronic rheumatism*; they may be given by simply evaporating oil of turpentine in the ordinary cabinet or other vapor bath, or by driving the vapor through the fine branches and leaves of a terebinthinate plant. They probably differ in their action from the simple hot vapor bath by the stimulation of the skin due to the local action of the turpentine, and by the copious sweating which they produce. The bath should always be so arranged that the terebinthinate vapor is not inhaled by the patient.

Dose, twenty to thirty grains (1.3 to 2 Gm.).

Off. Prep.—From *Canada turpentine*, Colloidium Flexile, U. S., Br.

TERPINI HYDRAS. U. S.

TERPIN HYDRATE

(tēr-pī'nī hŷ'drās)

"The hydrate [$\text{C}_{10}\text{H}_{18}(\text{OH})_2 + \text{H}_2\text{O}$] of the diatomic alcohol terpin. Terpin Hydrate should be kept in well-stoppered bottles." U. S.

Terpine, *Fr. Cod.*; Dihydrate de Térébenthène. Hydrate de Terpiène, *Fr.*; Terpinum hydratum, *P. G.*; Terpinhydrat, *G.*; Terpina, *Sp.*

In making terpin hydrate a mixture of four parts of rectified oil of turpentine, three parts of alcohol (sp. gr. 0.863), and one part of nitric acid is put in large, shallow porcelain dishes and allowed to stand for three or four days. The crystals which have formed are then collected and allowed to drain thoroughly; they are then pressed between sheets of absorbent paper, and recrystallized in a cold solution of 95 per cent. of alcohol. The product is about 12 per cent. of the original turpentine oil. E. T. Hahn proposed the use of methyl alcohol (sp. gr. 0.801) in place of alcohol, in making terpin hydrate. (*A. J. P.*, 1897, 73.) Terpin hydrate is officially described as in

"colorless, lustrous, rhombic prisms, nearly odorless, and having a slightly aromatic and somewhat bitter taste. Permanent in the air. Soluble in about 200 parts of water, and in 10 parts of alcohol at 25° C. (77° F.); in 32 parts of boiling water, and in 2 parts of boiling alcohol; also soluble in about 100 parts of ether, 200 parts of chloroform, or 1 part of boiling glacial acetic acid. Terpin Hydrate melts when quickly heated at 116° to 117° C. (240.8° to 242.6° F.), with the loss of water, and, at the temperature of boiling water, sublimes in fine needles. When heated in a flask adapted for distillation, it first loses water. At 258° C. (496.4° F.) anhydrous terpin distils over without decomposition, soon solidifying to a crystalline, hygroscopic mass, which melts at 102° to 105° C. (215.6° to 221° F.). When strongly heated on platinum foil, it burns with a bright, smoky flame, leaving no residue. If to its hot, aqueous solution a few drops of sulphuric acid be added, the liquid will become turbid and develop a strongly aromatic odor. Terpin Hydrate should not have the odor of turpentine, and its hot, aqueous solution should not redden blue litmus paper." U. S. The anhydrous terpin $\text{C}_{10}\text{H}_{18}(\text{OH})_2$, obtained from it by the loss of water has the characters of a glycol. Dipentene dihydrochloride is its hydrochloric acid ether. By the loss of water the terpin then becomes *terpineol*, $\text{C}_{10}\text{H}_{17}(\text{OH})$, and finally yields dipentene, terpinene, or terpinolene, according to the conditions of its treatment. Bouchardat and Voiry obtained *terpineol* in crystals which melt at 35° C. and remain in superfusion for long periods. (*Ann. Ch. Ph.*, 1893, 103.) For Wallach's researches on crystallized *terpineol*, see *P. J.*, 1893, 2.

L. Krentmann states that good results are obtained by replacing the alcohol in the process with hydrogen dioxide solution and subjecting the mixture poured into shallow dishes to light and air. The temperature should be carefully regulated so that the range will be between 15° and 20° C.

Uses.—Terpin was first physiologically investigated by Lépine, in 1855, who found it to act both upon the mucous membranes and upon the nervous system in a manner similar to the oil of turpentine. It has since been used in *chronic bronchitis* and in the advanced stages of *acute bronchitis*, especially when the secretion is unusually free; also in *chronic cystitis* and *gonorrhœa*.

Dose, two to three grains (0.13 to 0.2 Gm.), from four to six times a day, in pill or in emulsion.

THYMOL. U. S., Br.

THYMOL

(thŷ'mōl)

"A phenol [$\text{C}_6\text{H}_5(\text{CH}_3)(\text{OH})(\text{C}_6\text{H}_7)1:3:4$] occurring in the volatile oil of *Thymus vulgaris*

Linné, and in some other volatile oils. It should be kept in well-stoppered bottles." *U. S.* "A crystalline substance, $C_6H_5.OH.CH_3.C_6H_7$, obtained from the volatile oils of *Thymus vulgaris*, Linn., *Monarda punctata*, Linn., and *Carum copticum*, *Benth. and Hook. f.*, purified by recrystallization from alcohol." *Br.*

Acidum Thymicum; *Thymic Acid*; *Thymol, Acide Thymique*, *Fr. Cod.*; *Thymolum*, *P. G.*; *Thymol*, *Thymiansaure*, *Thymolkampher*, *G.*; *Timolo*, *It.*; *Timol*, *Sp.*

This substance has attracted considerable attention from its possession of antiseptic properties analogous to those of phenol, salicylic acid and creosote, with which it is also analogous in composition. It may be obtained by submitting the volatile oils of several plants to a prolonged refrigeration, under the influence of which it crystallizes. Thus, it has been obtained from *Monarda didyma*, Linn., *M. punctata* and *Ptychotis coptica* (L.), Lyons (*Ammi copticum*, L., *P. Ajowan*, DC.). *Ocimum viride*, Willd., a plant which is used in Liberia as an antiperiodic, and is said to be especially valuable owing to the fact that when growing in a room it will drive mosquitoes out of the apartment, as well as the medicinally active *O. gratissimum* of India, probably depend for their activities upon thymol. (*Proc. A. Ph. A.*, xxvi. 168.) Thymol is obtained from the oils of thyme by distilling off from these the larger part of the hydrocarbons and adding warm sodium hydroxide solution to the residue, which combines with the thymol. The mixture is diluted after a time with hot water, which causes the unattacked oil to rise to the top. From the sodium hydroxide solution hydrochloric acid sets the thymol free. This collects as an oily layer, which on cooling will crystallize if a crystal of thymol is added.

Properties.—Thymol melts at $44^\circ C.$ ($111.2^\circ F.$), but does not readily resolidify unless touched by a solid body or by a crystal of thymol. It boils at 220° to $230^\circ C.$ (428° to $446^\circ F.$). It is very slightly soluble in water, but is very soluble in alcohol, and more freely in proportion to the concentration of the menstruum. It is dissolved by ether and the fixed oils, and has no rotatory power as regards polarized light. The alkalis unite with it to form soluble salts. Like creosote, it has the property of combining with animal tissues and thus protecting them against putrefaction. Its

formula is $C_{10}H_{14}O$, or $C_6H_5 \begin{cases} OH \\ CH_3; \text{ while} \\ C_6H_7 \end{cases}$

thymene, with which it is associated in the oil, is a hydrocarbon, isomeric with the oil of turpentine, and having the composition $C_{10}H_{16}$. As its formula indicates, it is a *propyl-cresol*; and it has been made synthetically by Widmann from cuminol (isopropyl benzaldehyde). This is first nitrated, then by means of phosphorus pentachloride the oxygen of the aldehyde group replaced by chlorine, the nitro group reduced, the chlorine replaced by hydrogen, and

the amide group replaced by hydroxyl. The successive changes are thus indicated:

A process has been patented by M. Dinesman for making *synthetic thymol* from *p* cymol (see *Ph. Centralh.*, Oct. 1901, 650).

Thymol is described in the *U. S. P.* (8th Rev.) as in "large, colorless, translucent rhombic prisms, having an aromatic, thyme-like odor, and a pungent, aromatic taste, with a very slight caustic effect upon the lips. Its specific gravity as a solid is 1.030 at $25^\circ C.$ ($77^\circ F.$), but when liquefied by fusion it is lighter than water. It melts at 50° to $51^\circ C.$ (122° to $123.8^\circ F.$), remaining liquid at considerably lower temperatures. When triturated with about equal quantities of camphor, menthol, or hydrated chloral, it liquefies. Soluble in about 1100 parts of water at $25^\circ C.$ ($77^\circ F.$), and in less than its own weight of alcohol, ether, or chloroform; soluble in glacial acetic acid and fixed and volatile oils. Its alcoholic solution is optically inactive. If a very small crystal of Thymol be dissolved in 1 Cc. of glacial acetic acid, and then 6 drops of sulphuric acid and 1 drop of nitric acid be added, the liquid will assume by reflected light a deep bluish-green color. If 1 Gm. of Thymol be heated in a test-tube, in a water-bath, with 5 Cc. of a 10 per cent. solution of sodium hydroxide, a clear, colorless, or very slightly reddish solution should be formed, which becomes darker on standing, but without the separation of oily drops. If to this solution a few drops of chloroform be added and the mixture agitated, a violet color will be produced. An alcoholic solution of Thymol should not be colored by ferric chloride T.S. When a crystal of Thymol is heated in an open dish, or in a watch-glass, on a water-bath, it should gradually volatilize, leaving no residue (absence of *inorganic impurities*)." *U. S.* "The crystals sink in cold water, but on heating the mixture to a temperature of 110° to $125^\circ F.$ (43.3° to $51.7^\circ C.$) they melt and rise to the surface. Almost insoluble in cold water, freely soluble in alcohol (90 per cent.), ether, and solutions of alkalis. The crystals volatilize completely at the temperature of a water-bath. A solution of Thymol in half its bulk of *glacial acetic acid*, warmed with an equal volume of *sulphuric acid*, assumes a reddish-violet color." *Br.*

Uses.—Thymol is similar in its physiological and general therapeutic action to phenol, as a substitute for which it was proposed by Bouillon on account of its pleasant odor. In a concentrated state it has caustic properties,

which render it very useful for the cauterization of the dental nerves. Dissolved in water in the proportion of 1 to 1000, with the addition of a little alcohol, it is useful in the dressing of *unhealthy wounds*. Combined in the proportion of 4 parts of thymol with 4 of tannin, 2 of aniline, and 100 of glycerin, it has been used with great success by Paquet for the preservation of anatomical specimens. For the dressing of wounds, it may be used in the form of a lotion composed of 1 part of thymol, 4 parts of alcohol of 85°, and 995 parts of distilled water. In the form of ointment, it may be employed incorporated with lard in the proportion of from two to twenty grains to an ounce. At first much used by surgeons, it has been found disadvantageous. Its fragrant odor, while fitting it for use about the mouth, is often a great nuisance in the hospital ward, on account of attracting flies. It has been exhibited internally as an antipyretic by Balz in the amount of thirty grains (1.95 Gm.) a day, causing ringing in the ears, deafness, sweating, and in some cases alarming collapse. F. P. Henry has found it a useful intestinal antiseptic, especially valuable in *catarrh of the intestines*, given in doses of two and a half grains (0.162 Gm.) every six hours, in pill or capsule. Thymol has, however, failed to come into use as an internal remedy save as a vermicide; originally proposed by Neuma Campi as a tannicide; it has been shown by Federici, Sandwith and other clinicians to be the most effective known remedy against the ankylostoma. Sandwith gives it in thirty-grain doses, repeated in twenty-four hours, the result being the destruction of the parasites, but attended with great giddiness, lowering of the temperature from 1° to 2° C., slowing of the pulse and respiration, staggering, and sometimes even collapse.

Dose, two to ten grains (0.13 to 0.65 Gm.).

Off. Prep.—Cataplasma Kaolini, *U. S.*; Liquor Antisepticus, *U. S.*

THYMOLIS IODIDUM. *U. S.*

THYMOL IODIDE

(thÿ-mô'lis i-ôd'î-dûm)

$C_{20}H_{20}O_2I_2 = 545.76$

"Dithymol-diiodide [$(C_6H_2.CH_3.C_6H_7.OI)_2$], obtained by the condensation of two molecules of thymol and the introduction of two atoms of iodine into the phenolic groups of the thymol; it contains 45 percent. of iodine. Thymol Iodide should be kept in amber-colored vials, protected from the light." *U. S.*

Dithymoldiiodide: Aristol; Aristolum; Dithymoldithymol, *Fr. Cod.*; Dithymol Bliodé, *Fr.*; Dithymoldiiod, Aristol, Annidallin, Thymotol, *G.*; Aristol, *Sp.*

Preparation.—Thymol iodide contains about 45 per cent. of iodine; it is the product of the condensation of two molecules of thymol and the substitution of the hydrogen in the hydroxyl group in each by iodine. It may be prepared by decomposing a solution of iodine

in potassium iodide by an alcoholic solution of thymol. For process, see *A. J. P.*, 1891, 175; *Proc. A. Ph. A.*, 1891, 572; *Bull. Pharm.*, 1891, 260. The Cincinnati Academy of Pharmacy published the following formula for thymol iodide: Thymol, 50 Gm.; potassium iodide, 58 Gm.; sodium hydroxide, 50 Gm.; solution of chlorinated soda, water, of each a sufficient quantity. Dissolve the solids in the solution with sufficient water to make 500 Cc. Collect the precipitate on a filter and wash it with water until it is free from chlorides. Remove the precipitate and dry it carefully at a temperature not exceeding 20° C. Reduce it to powder and keep it in a well-stoppered dark bottle. (*Am. Drug.*, 1898, 130.) The French Codex directs that two solutions be made, one by dissolving 16 Gm. of sodium hydroxide and 15 Gm. of thymol in sufficient water to make the solution measure 300 Cc. The other solution is made by dissolving 60 Gm. of iodine and 80 Gm. of potassium iodide in enough water to make the solution measure 300 Cc., the latter solution is added gradually to the alkaline solution of thymol with constant stirring; the resulting brown precipitate is washed with water and the product dried between 40° C. and 50° C.

Properties.—Thymol Iodide occurs as "a bright, chocolate-colored, or reddish-yellow, bulky powder, with a very slight aromatic odor. Insoluble in water and glycerin; slightly soluble in alcohol at 25° C. (77° F.); readily soluble in ether, chloroform, collodion, and in fixed and volatile oils, leaving a slight residue." *U. S.* The ethereal solution is precipitated by alcohol; when heated to the melting point it undergoes decomposition. The *U. S.* requires that it should answer to the following tests. "It is not soluble in solution of sodium hydroxide, either cold or warm. When heated with concentrated sulphuric acid, it is decomposed with the separation of iodine. If 0.5 Gm. be shaken with 10 Cc. of water, the mixture, on filtering, will yield a filtrate which should not become more than opalescent on the addition of nitric acid and silver nitrate T.S. (absence of *iodides*). If 0.5 Gm. be shaken with 10 Cc. of water, and the mixture filtered, no blue color should be imparted by the filtrate to red litmus paper (absence of *alkalies*). If 0.5 Gm. be shaken with 10 Cc. of water, and the mixture filtered, the filtrate should not be colored blue upon the addition of starch T.S. (absence of *free iodine*). If 0.1 Gm. of Thymol Iodide be thoroughly ignited in a porcelain crucible, it should leave not more than 0.003 Gm. of residue (limit of *ash*)." *U. S.*

Uses.—Eichhoff first stated that thymol iodide is a non-toxic and non-irritant application, having similar local properties to iodoform, and useful in the treatment of superficial ulcerations, eczema, psoriasis, and various other skin affections. The non-poisonous properties of it have been confirmed by Neisser, Quinquaud, and Fournioux. The mode of its elimination from the system has not been thor-

oughly worked out, but it appears to be partially decomposed, as iodine has been found in the urine after its ingestion. Neisser found that the powder has no effect upon the lower organisms, although its ethereal solution is germicidal, probably through decomposition of the thymol iodide and the liberation of iodic compounds as occurs with iodoform. It may be used as a substitute for iodoform, but the general trend of the reports is that it is not equal in antiseptic surgery to iodoform. It is, however, considerably used, especially in affections of the membranes of the nose and larynx. It has been employed by suppository¹ in chronic dysentery, three grains (0.2 Gm.) three times a day, with alleged excellent results.

Dose, from two to three grains (0.13 to 0.2 Gm.).

TINCTURA ACONITI. U. S., Br.

TINCTURE OF ACONITE

(tinc-tū'rā āc-q-nī'ti)

"NOTE.—The strength of this Tincture has been reduced from 35 Gm. of Aconite in 100 Cc. (Pharm. 1890) to 10 Gm. of Aconite in 100 Cc." U. S.

Tinctura Aconiti Radicis, U. S. 1870; Tincture of Aconite Root; Teinture de racine d'Aconit, Fr. Cod.; Tinctura Aconiti, P. G.; Aconittinktur, Eisenhuttinktur, G.; Tintura di acconito, It.; Tintura alcoholica de acconito, Sp.

* "Aconite, in No. 60 powder (containing not less than 0.5 percent. of aconitine), *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, Water, each, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix Alcohol and Water in the proportion of *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims] of Alcohol to *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water. Moisten the Aconite with *forty cubic centimeters* [or 1 fluidounce, 169 minims] of this menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it very firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum until *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] are obtained. Tincture of Aconite,

when assayed by the process given below, should contain in *one hundred cubic centimeters* 0.045 Gm. of aconitine." U. S.

Assay. U. S. (8th Rev.).—"Transfer 100 Cc. of Tincture of Aconite to an evaporating dish and evaporate it carefully to dryness at a temperature not exceeding 60° C. (140° F.), and assay the resulting extract by the method given under *Fluidextractum Aconiti*, page 526, using the same details as there directed for 10 Cc. of Fluidextract of Aconite, with the exception that the multiplication of the product by 10 must be omitted; the result will represent the weight in grammes of aconitine contained in *one hundred cubic centimeters* of Tincture of Aconite." U. S.

"Aconite Root, in No. 40 powder, 1 ounce (Imperial) or 50 grammes; Alcohol (70 per cent.), a *sufficient quantity*. Moisten the powder with *four fluid drachms* (Imp. meas.) or twenty-five cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres. This preparation is made with two-fifths the proportion of Aconite Root ordered for the Tincture of Aconite of the British Pharmacopœia of 1885." Br.

The old tincture of the U. S. Pharmacopœia 1890 had seven times the strength of the British, and the title was changed from *Tinctura Aconiti Radicis* to *Tinctura Aconiti* in the U. S. 1880 revision. It was much stronger than the Tincture of Aconite Leaves, which is still used occasionally, and made of the strength of two troyounces of powdered aconite leaves in a pint of diluted alcohol, and too much caution cannot be observed to avoid mistaking one tincture for the other. A very important change was made in the strength of Tincture of Aconite in the U. S. P. (8th Rev.), see page 1252. The former 35 per cent. tincture is now replaced by a tincture of 10 per cent. An assay process was also appended (see above). In preparing it, each step of the process must be carefully attended to. The root should be thoroughly comminuted, and very carefully packed in the percolator, and the displacing menstruum very gradually added. Tartaric acid which was formerly used in accordance with the researches of Duquesnel in the U. S. 1880 tincture has been abandoned, as it was found to be unnecessary. For a paper on Tincture of Aconite by M. I. Wilbert see *Proc. A. Ph. A.*, 1902, 348. The external use of the tincture requires care, as serious symptoms have followed its too free employment. (Case, *B. M. S. J.*, Feb. 1872, 74.)¹

¹ *Aristol Ointments*.—Osseward, *Proc. A. Ph. A.*, 1901, 176, obviates the difficulty of obtaining smooth ointments of aristol (which most dispensers have experienced when proceeding in the usual way) by adding sufficient ether to 1 oz. of aristol placed in a dry mortar, to form a paste, then stirring in 1 oz. of olive oil until a smooth paste is obtained; the ether can be dissipated during the stirring, and this 50 per cent. mixture used in making ointments by incorporating with fatty substances.

¹ *Fleming's Tincture of Aconite*.—This should always be expressly designated when prescribed. It is considerably stronger than the official; and several deaths have occurred from the use of it. The following is Fleming's formula: Take of the root, carefully dried and finely powdered, *sixteen (troy) ounces*; Alcohol, *sixteen fluidounces*. Macerate for four days, put into a percolator, and add alcohol until twenty-four fluidounces are obtained. Not more than two drops of this should be given as a commencing dose, to be increased till its peculiar effects are experienced.

Dose, of the U. S. tincture, three to ten minims (0.2 to 0.6 Ce.); of the Br. tincture, five to fifteen minims (0.3 to 0.9 Ce.).

TINCTURA ALOES. U. S., Br.

TINCTURE OF ALOES

(tinc-tū'ra āl'q-ēs)

Tincture (alcoolé) d'Aloés, *Fr. Cod.*; Tinctura Aloës, *P. G.*; Aloetinktur, *G.*; Tinctura alcoholica de acibar, *Sp.*

* "Purified Aloes, in No. 40 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Glycyrrhiza, in No. 40 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Diluted Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Macerate the Purified Aloes and Glycyrrhiza in a stoppered container, in a moderately warm place, with *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Diluted Alcohol, for seven days, with occasional agitation; then filter through purified cotton, or a plain paper filter, and, when the liquid has drained off completely, pass enough Diluted Alcohol through the residue to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

"Extract of Barbados Aloes, ½ ounce (Imperial) or 25 grammes; Liquid Extract of Liquorice, 3 fl. ounces (Imp. meas.) or 150 cubic centimetres; Alcohol (45 per cent.), *a sufficient quantity*. Place the Extract of Barbados Aloes in a closed vessel with *sixteen fluid ounces* (Imp. meas.) or eight hundred cubic centimetres of the Alcohol; set aside for forty-eight hours, occasionally shaking until dissolved; add the Liquid Extract of Liquorice; filter; pass sufficient of the Alcohol through the filter to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture." *Br.*

The original tincture of aloes of the U. S. Pharmacopœia was prepared with the official diluted alcohol, without the addition of water. The preparation of the U. S. P. 1870 was little more than an infusion, with the addition of sufficient alcohol to prevent spontaneous decomposition. The process of the Br. Pharm. 1898 shows a marked improvement on the former British tincture. Barbados aloes replaces Socotrine, liquid extract of liquorice is used instead of the solid extract, and the time for making the tincture is reduced from a week to two days. The strength of the British tincture is only one-fourth that of the U. S. tincture. The formula of the U. S. (8th Rev.) directs glycyrrhiza instead of extract of licorice, but has returned to the process of maceration for its preparation. Ménière says of the tincture of aloes that it deposits crystals of aloin, which adhere to the sides of the bottle, and in the upper part of it a yellow resinous matter is seen. (*J. P. C.*, 1861, 289.)

Dose, as a purgative, from two to four fluidrachms (7.5 to 15 Ce.); as a laxative, from one-half to one fluidrachm (1.8 to 3.75 Ce.).

TINCTURA ALOES ET MYRRHÆ. U. S.

TINCTURE OF ALOES AND MYRRH

(tinc-tū'ra āl'q-ēs ēt mý'r'hæ)

Tinctura Aloes Composita, *Lond.*; Elixir Proprietatis Paracelsi; Elixir de Propriété, *Fr.*; Aloëelixir, *G.*

* "Purified Aloes, in No. 40 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Myrrh, in No. 40 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Glycyrrhiza, in No. 40 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water. Macerate the Purified Aloes, Myrrh, and Glycyrrhiza in a stoppered container, in a moderately warm place, with *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of the menstruum, for seven days, with occasional agitation; then filter through purified cotton, or a plain filter, and, when the liquid has drained off completely, pass enough menstruum through the residue to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

This tincture has been improved by the addition of glycyrrhiza, which not only communicates an agreeable taste and obtunds the bitterness of the aloes, but also permits the use of percolation. The tincture is a modification of the *elixir proprietatis* of Paracelsus. It is practically identical with the tincture official in 1870. Saffron, which had long been retained in compliance with old time prejudices, can add little to the efficacy of a preparation, and, being very expensive, was with great propriety omitted in the 1870 revision. It served, however, to impart a rich color to the tincture, the want of which some may consider a defect. In the U. S. P. (8th Rev.) the maceration process has been directed instead of percolation as in the U. S. P. 1890. The tincture is purgative, tonic, and emmenagogue, and is considerably employed in *chlorosis* and *amenorrhœa* when there is constipation.

Dose, from one to two fluidrachms (3.75 to 7.5 Ce.).

TINCTURA ARNICÆ. U. S., Br.

TINCTURE OF ARNICA [Tinctura Arnicae Florum, Pharm. 1890]

(tinc-tū'ra ār'ni-cæ)

Tincture of Arnica Flowers, U. S. P. 1890; Teinture (alcoolé) de Fleur d'Arnica, Teinture d'Arnica, *Fr. Cod.*; Tinctura Arnicae, *P. G.*; Arnkatinktur, *G.*; Tintura di Arnica, *It.*; Tinctura alcoholica de arnica, *Sp.*

* "Arnica, in No. 20 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Diluted Alcohol, *a sufficient quantity*, to make *one*

thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Macerate the Arnica with five hundred cubic centimeters [or 16 fluidounces, 435 minims] of Diluted Alcohol in a closed vessel, in a moderately warm place, for three days, with occasional stirring, and express strongly. Repeat this operation twice successively with two hundred and fifty cubic centimeters [or 8 fluidounces, 218 minims] of Diluted Alcohol, macerating for twenty-four hours each time; then, having ascertained the volume of the united expressed liquids, macerate the residual marc for six hours with sufficient menstruum to make approximately one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms], and express as before. Mix the expressed liquids, filter through paper, and pass sufficient Diluted Alcohol through the filter to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Tincture." U. S.

"Arnica Rhizome, in No. 40 powder, 1 ounce. (Imperial) or 50 grammes; Alcohol (70 per cent.), a sufficient quantity. Moisten the powder with one fluid ounce (Imp. meas.) or fifty cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure one pint (Imp. meas.) or one thousand cubic centimetres." Br. *Tincture of Arnica Root* formerly official in the U. S. P. 1890 was made by percolating 100 Gm. of powdered arnica root with a mixture of alcohol 65 and water 35 until 1000 Cc. of finished tincture was obtained.

The British tincture has about one-half the strength of the U. S. P. 1890 tincture of arnica root.

Care must be used to distinguish between these tinctures which now have the same names in both Pharmacopœias. The name of the U. S. P. (8th Rev.) tincture is no longer tincture of arnica flowers but tincture of arnica. The British tincture is made from the rhizome or root and is very different from the U. S. P. tincture of the flowers; in the U. S. P. 1890 there were two tinctures of arnica, one from the root, and one from the flowers, but the U. S. P. (8th Rev.) dropped tincture of arnica root and retained tincture of arnica flowers, changing its name however to tincture of arnica, this action makes it necessary to use care not to confuse the U. S. P. tincture of arnica made from the flowers, with the Br. tincture made from the root.

The U. S. P. (8th Rev.) tincture of arnica differs from that official in 1870 in the menstruum selected, which is now diluted alcohol in place of alcohol. The change was advocated by numerous pharmaceutical writers, and there is no question of the ability of the menstruum to exhaust the arnica flowers, if they are tightly packed in the percolator. The principal objection to the change is the greater difficulty that will be experienced in mixing the tincture with liniments containing oily and alcoholic liquids.

Either alone, or diluted with water, soap liniment, etc., tincture of arnica is often applied

popularly to bruises, sprains, tumors, and local rheumatic pains, under the impression that it has extraordinary healing powers. It probably acts favorably in some instances as a general irritant. In some skins it produces a violent eczematous inflammation. If given internally, the dose would be from ten to thirty minims (0.6 to 1.8 Cc.), increased until some effect was produced.

Dose, of the British tincture of the rhizome, twenty minims to half a fluidrachm (1.3 to 1.8 Cc.).

TINCTURA ASAFETIDÆ. U.S., Br.

TINCTURE OF ASAFETIDA

(tinc-tū'ra ās-ā-fet'id-æ)

Teinture (alcoolé) d'Asa fetida, Fr. *Od.*; Asantinktur, Stinkasantinktur, G.; Tintura alcoholica de asafetida, Sp.

* "Asafetida, well bruised, two hundred grammes [or 7 ounces av., 24 grains]; Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Macerate the Asafetida in a stoppered container, in a moderately warm place, with seven hundred and fifty cubic centimeters [or 25 fluidounces, 173 minims] of Alcohol, during three days, with frequent agitation; then filter through purified cotton, or a plain paper filter, and, when the liquid has drained off completely, pass enough Alcohol through the residue to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Tincture." U. S.

"Asafetida, bruised, 4 ounces (Imperial) or 200 grammes; Alcohol (70 per cent.), a sufficient quantity. Place the Asafetida in a closed vessel with fifteen fluid ounces (Imp. meas.) or seven hundred and fifty cubic centimetres of the Alcohol; set aside for seven days, with occasional agitation; filter; pass sufficient of the Alcohol through the filter to produce one pint (Imp. meas.) or one thousand cubic centimetres of the Tincture." Br.

The British tincture (1898) was increased in strength 60 per cent., and is now identical with the U. S. P. preparation. This tincture becomes milky on the addition of water, in consequence of the separation of the resin. It is somewhat stronger than the tincture official in 1870, which is an improvement, particularly in view of the gradual decline in the quality of the drug.

Dose, thirty minims to a fluidrachm (1.8 to 3.75 Cc.).

TINCTURA AURANTII AMARI. U.S. (Br.)

TINCTURE OF BITTER ORANGE PEEL

(tinc-tū'ra āu-rān'ti-i ā-mā'ri)

Tinctura Aurantii, Br.; Tincture of Orange; Teinture (alcoolé) d'Ecorce d'Orange amère, Fr.; Tinctura Aurantii, P. G.; Pomeranzentinktur, Pomeranzenschalentinktur, G.

* "Bitter Orange Peel, in No. 40 powder, two hundred grammes [or 7 ounces av., 24

grains]; Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix six hundred cubic centimeters [or 20 fluidounces, 138 minims] of Alcohol with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Water. Moisten the Bitter Orange Peel with eighty cubic centimeters [or 2 fluidounces, 338 minims] of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, gradually pouring on sufficient menstruum to obtain one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

"Fresh Bitter Orange Peel, cut small, 5 ounces (Imperial) or 250 grammes; Alcohol (90 per cent.), 1 pint (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

It is the peel of the Seville orange that is directed in this process, and the outer part only is active. The substitution of fresh for dried orange peel was proposed in England, and its propriety considerably discussed. (See *P. J.*, Nov. 9, 1872, also April 4, 1874.) Indeed, it met with so much favor as to be introduced in the 1885 revision of the British Pharmacopœia, and was used in the *Tinctura Aurantii Recentis*, *Br.*; but in the *Br. Pharm.* 1898 the name was changed to *Tinctura Aurantii*. It will be seen that the *U. S.* and British tinctures are not identical, the former having a greenish-brown color and containing some hesperidin or bitter principle. The *U. S.* Tincture of Sweet Orange Peel (see next article) closely resembles the British Tincture of Orange. The tincture from the fresh peel is less powerful as a bitter than this preparation, but is much superior in aroma and flavor. (See *Tinctura Aurantii Dulcis*.) The tincture of bitter orange peel is employed as a grateful addition to infusions, decoctions, and mixtures.

Dose, from one to two fluidrachms (3.75 to 7.5 Cc.).

Off. Prep.—*Confectio Sulphuris*, *Br.*; *Syrupus Aromaticus*, *Br.*; *Syrupus Aurantii*, *Br.*; *Syrupus Cascaræ Aromaticus*, *Br.*; *Tinctura Quinina*, *Br.*; *Trochiscus Sulphuris*, *Br.*

TINCTURA AURANTII DULCIS. U.S.

TINCTURE OF SWEET ORANGE PEEL

(tinc-tû'râ au-rân'tî-i dû'l'cis)

Teinture de Zeste d'Orange douce, *Fr.*; *Apfelsinenschalentinktur*, *G.*

* "Sweet Orange Peel, from the fresh fruit, in thin shavings and cut into narrow shreds, five hundred grammes [or 17 ounces av., 279

grains]; Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Macerate the Sweet Orange Peel in a stoppered wide-mouthed container and in a moderately warm place, with one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Alcohol, during forty-eight hours, with frequent agitation; then filter through purified cotton, and, when the liquid has drained off completely, gradually pass enough menstruum through the residue to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Tincture; finally, filter it through paper." *U. S.*

This tincture was introduced for the first time in the *U. S. P.* 1880, and was designed to furnish a highly flavored alcoholic preparation of orange. The official direction to cut it into small pieces was not definite enough if a successful percolation is desired, but the *U. S. P.* (8th Rev.) directs maceration and a large increase of strength, from 20 per cent. to 50 per cent. This tincture has no peculiar medicinal properties, but is used as a pleasant adjuvant and flavoring agent.

Off. Prep.—*Syrupus Aurantii*, *U. S.*; *Vinum Ferri*, *U. S.*; *Vinum Ferri Amarum*, *U. S.*

TINCTURA BELLADONNÆ FOLIORUM. U. S. (Br.)

TINCTURE OF BELLADONNA LEAVES

(tinc-tû'râ bē'l'lâ-dō'n'æ fō-lî-ō'rūm)

Tinctura Belladonnæ, *Br.*, *U. S. P.* 1880; *Tincture of Belladonna*; *Teinture de feuille de Belladone*, *Fr. Cod.*; *Belladonnatinktur*, *G.*; *Tintura alcoholica de belladonna*, *Sp.*

* "Belladonna Leaves, in No. 60 powder (containing not less than 0.35 percent. of alkaloids), one hundred grammes [or 3 ounces av., 231 grains]; Diluted Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with forty cubic centimeters [or 1 fluidounce, 169 minims] of Diluted Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for three hours; then pack it firmly and pour on enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, gradually pouring on Diluted Alcohol until one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of percolate are obtained. Tincture of Belladonna Leaves, when assayed by the process given below, should contain in one hundred cubic centimeters 0.035 Gm. of the alkaloids from Belladonna Leaves." *U. S.*

Assay. *U. S.* (8th Rev.)—"Transfer 100 Cc. of Tincture of Belladonna Leaves to an evaporating dish and evaporate it on a water-bath until it measures about 10 Cc. Add, if

necessary, sufficient alcohol to dissolve any separated substance, and then assay the resulting liquid by the method given under *Fluidextractum Belladonnæ Radicis* (page 528), using the same details as there directed for 10 Cc. of Fluidextract of Belladonna Root, with the exception that the multiplication of the product by 10 be omitted; the result will represent the weight in grammes of alkaloids contained in one hundred cubic centimeters of Tincture of Belladonna Leaves." U. S.

"Liquid Extract of Belladonna, 2 fl. ounces (Imperial measure) or 60 cubic centimetres; Alcohol (60 per cent.), a sufficient quantity. To the Liquid Extract of Belladonna add enough of the Alcohol to form thirty fluid ounces (Imp. meas.) or nine hundred cubic centimetres of the Tincture; set aside for twenty-four hours; filter. On evaporation to a low bulk, and subsequent treatment by the analytical process employed for 'Extractum Belladonnæ Liquidum,' 100 cubic centimetres of the Tincture should yield not less than 0.048 nor more than 0.052 gramme of alkaloid." Br.

In the U. S. P. 1890 the name of this tincture was changed to *Tinctura Belladonnæ Foliorum*, for the sake of greater precision. In the U. S. P. (8th Rev.) its strength was reduced about 33 per cent. The British tincture (1898) is made by diluting the assayed fluidextract of belladonna root, and is undoubtedly more uniform in composition than would be the unassayed tincture made from the leaves.

The U. S. tincture is an efficient preparation when made from the recently dried leaves and assayed by the official process.

Dose, of U. S. tincture, from ten to thirty minims (0.6 to 1.8 Cc.). That of the British tincture is from five to fifteen minims (0.3 to 0.9 Cc.).

TINCTURA BENZOINI. U. S.

TINCTURE OF BENZOIN

(tinc-tū'ra bēn-zō-'ī-nī)

Teinture (alcoolé) de Benjoin, *Fr. Cod.*; Tinctura Benzoë, *P. G.*; Benzoëintur, *G.*; Tintura di benzoino, *It.*; Tintura alcoolica de benjui, *Sp.*

* "Benzoin, in No. 40 powder, two hundred grammes [or 7 ounces av., 24 grains]; Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Triturate the Benzoin with two hundred and fifty cubic centimeters [or 8 fluidounces, 218 minims] of Alcohol until a uniform magma is obtained. Transfer this to a stoppered container with the aid of five hundred cubic centimeters [or 16 fluidounces, 435 minims] of Alcohol, and set it aside in a moderately warm place, shaking frequently during three days. Then transfer the mixture to a paper filter, and, when the liquid has drained off completely, pour on enough Alcohol to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Tincture." U. S.

This tincture was introduced into the Pharmacopœia chiefly or solely for the purpose of adding to ointments to prevent rancidity.

Dose, twenty to thirty minims (1.3 to 1.8 Cc.). *

TINCTURA BENZOINI COMPOSITA.

U. S., Br.

COMPOUND TINCTURE OF BENZOIN

(tinc-tū'ra bēn-zō-'ī-nī cōm-pōs'ī-tā)

Tinctura Balsamica, Balsamum Commendatoris, Elixir Traumaticum; Teinture (alcoolé) balsamique, *Fr. Cod.*; Baume du Commandeur de Permes, *Fr.*; Persischer Wundbalsam, *G.*

* "Benzoin, in No. 40 powder, one hundred grammes [or 3 ounces av., 231 grains]; Purified Aloes, in No. 40 powder, twenty grammes [or 309 grains]; Storax, eighty grammes [or 2 ounces av., 360 grains]; Balsam of Tolu, forty grammes [or 1 ounce av., 180 grains]; Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Triturate the Benzoin and Purified Aloes with two hundred and fifty cubic centimeters [or 8 fluidounces, 218 minims] of Alcohol until a uniform magma is obtained. Transfer this to a stoppered container with the aid of five hundred cubic centimeters [or 16 fluidounces, 435 minims] of Alcohol, add the Storax and Balsam of Tolu, and set the mixture aside in a moderately warm place, shaking it frequently during three days; then transfer it to a paper filter, and, when the liquid has drained off completely, pour on enough Alcohol to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Tincture." U. S.

"Benzoin, in coarse powder, 2 ounces (Imperial) or 100 grammes; Prepared Storax, 1½ ounces (Imp.) or 75 grammes; Balsam of Tolu, ½ ounce (Imp.) or 25 grammes; Socotrine Aloes, 160 grains or 18.3 grammes; Alcohol (90 per cent.), a sufficient quantity. Place the Benzoin, Storax, Balsam of Tolu, and Aloes with sixteen fluid ounces (Imp. meas.) or eight hundred cubic centimeters of the Alcohol in a closed vessel, set aside for two days, frequently agitating; filter; pass sufficient of the Alcohol through the filter to produce one pint (Imp. meas.) or one thousand cubic centimeters of the Tincture." Br.

Compound tincture of benzoin now contains 10 per cent. of benzoin instead of 12 as in the U. S. P. 1890.

This tincture is a stimulating expectorant, occasionally used in chronic catarrhal affections. It has been recommended also in chronic dysentery, with a view to its alterative action on the ulcerated surface of the colon, but it is principally employed as a local application to indolent ulcers, chapped nipples, etc. It is the balsamum traumaticum of the older Pharmacopœias, and may be considered as a simplified form of certain complex compositions, such as baume du commandeur, Wade's balsam, Friar's balsam. Jesuit's drops, Turlington's

balsam,¹ etc., which were formerly in great repute, and are still esteemed by the people, as pectorals and vulneraries. The compound tincture of benzoin is decomposed by water. A variety of *court plaster* is made by applying to black silk, by means of a brush, first a solution of isinglass, and afterwards an alcoholic solution of benzoin.

Dose, from fifteen minims to one fluidrachm (0.9 to 3.75 Cc.).

TINCTURA BUCHU. Br.

TINCTURE OF BUCHU

(tinc-tū'ra bū'gū)

Teinture (alcoolé) de Buchu, *Fr. Cod.*; Teinture de Bucco, *Fr.*; Buchutinktur, *G.*

"Buchu Leaves, in No. 20 powder, 4 ounces (Imperial) or 200 grammes; Alcohol (60 per cent.), a sufficient quantity. Moisten the powder with four fluid ounces (Imp. meas.) or two hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure one pint (Imp. meas.) or one thousand cubic centimetres." *Br.*

This tincture was increased 60 per cent. in strength in the last revision of the *Br. Pharm.* It has the virtues of buchu leaves.

Dose, from one to two fluidrachms (3.75 to 7.5 Cc.), either simply diluted with water or as an addition to the infusion of the leaves.

TINCTURA CALENDULÆ. U. S.

TINCTURE OF CALENDULA

(tinc-tū'ra cā-lēn'dū-læ)

Tincture of Marigold; Teinture de Souci, Teinture de Fleur de Tous-les-Mois, *Fr.*; Calendulatinktur, Ringelblumentinktur, *G.*

* "Calendula, in No. 20 powder, two hundred grammes [or 7 ounces av., 24 grains]; Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the Calendula with eighty cubic centimeters [or 2 fluidounces, 338 minims] of Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it very firmly and pour on enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Alcohol to obtain one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

¹ The following is the formula for *Turritington's balsam*, adopted by the Philadelphia College of Pharmacy: "Take of Alcohol 8 pints, Benzoin 12 oz. troy, Liquid Storax 4 oz. troy, Socotrine Aloes 1 oz. troy, Peruvian Balsam 2 oz. troy, Myrrh 1 oz. troy, Angelica Root 240 gr., Balsam of Tolu 240 gr., Extract of Liquorice Root 4 oz. troy. Digest for ten days, and strain. (*A. J. P.*, v. 28.)

This tincture was improved in the 1890 revision by substituting alcohol as a menstruum for the diluted alcohol used in the 1880 process. It is employed externally for the same purposes as tincture of arnica. When made with diluted alcohol, some precipitation takes place; alcohol is therefore preferable as a menstruum, and on account of the tincture being used externally makes it more efficient therapeutically. It is not used internally.

TINCTURA CALUMBÆ. U. S., Br.

TINCTURE OF CALUMBA

(tinc-tū'ra cā-lūm'bæ)

Tinctura Colombo; Teinture (alcoolé) de Colombo, *Fr. Cod.*; Kolombotinktur, *G.*; Tintura alcoholica de colombo, *Sp.*

* "Calumba, in No. 20 powder, two hundred grammes [or 7 ounces av., 24 grains]; Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix six hundred cubic centimeters [or 20 fluidounces, 138 minims] of Alcohol with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Water. Moisten the Calumba with one hundred cubic centimeters [or 3 fluidounces, 183 minims] of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for twenty-four hours; then pack it with moderate pressure, pour on enough menstruum to saturate the powder and leave a stratum above it, and allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

"Calumba Root, in No. 20 powder, 2 ounces (Imperial) or 100 grammes; Alcohol (60 per cent.), 1 pint (Imp. meas.) or 1000 cubic centimeters. Prepare by the maceration process." *Br.*

This tincture was doubled in strength at the *U. S. P.* (8th Rev.) in order to bring it into the class of 20 per cent. non-potent tinctures.

Joseph Ince recommends that the tincture be prepared from the root as found in commerce, without further slicing or powdering it. Made as he proposes, the tincture is clear and bright; while if the powdered root is used it will be very turbid, even after filtration. (*P. J.*, xiv. 491.) No. 20 powder is now directed instead of the No. 50 powder used in the *U. S. P.* 1870.¹ Tincture of calumba may be added to tonic infusions or decoctions,

¹ *Tincture of Calumba*.—J. B. Moore recommends the following process: Calumba, in powder No. 20, 4 troy oz.; alcohol, 22 fl. oz.; glycerin and water, each 5½ fl. oz.; diluted alcohol, q. s. Mix the alcohol, glycerin, and water, moisten the powdered calumba with the mixture, pack in a close vessel, set aside to macerate for 6 hours; then pack in a glass funnel prepared for percolation, and gradually pour upon it the remainder of the menstruum, and, when this has passed from the surface, continue the percolation with the diluted alcohol until 32 fluidounces of tincture are obtained. (*D. C.*, May, 1877.)

to increase their stimulant power, but, like all the other bitter tinctures, should be used with caution.

Dose, one fluidrachm (3.75 Cc.).

TINCTURA CANNABIS INDICÆ.

U. S., Br.

TINCTURE OF INDIAN CANNABIS

(tinc-tū'ra cān'nā-bis in'dī-çæ)

Tinctura Cannabis, *Pharm.* 1870; Tincture of Hemp; Tincture of Indian Hemp; Teinture (alcoolé) de Chanvre de l'Inde, *Fr. Cod.*; Indischhaanfinktur, *G.*

* "Indian Cannabis, in No. 40 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the Indian Cannabis with *fifty cubic centimeters* [or 1 fluidounce, 331 minims] of Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it very firmly and pour on enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Alcohol to obtain *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

"Extract of Indian Hemp, 1 ounce (Imperial) or 50 grammes; Alcohol (90 per cent.), *a sufficient quantity*. Dissolve the Extract of Indian Hemp in *eighteen fluid ounces* (Imp. meas.) or nine hundred cubic centimetres of the Alcohol; filter if necessary; add sufficient of the Alcohol to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture." *Br.*

The American reader must take care not to confound the Indian Hemp here referred to with *Apocynum cannabinum*, known by the same name in this country. The term "Indian Hemp" should be dropped entirely, as its continued use has been the cause of at least one fatal mistake. The strength of the present tincture is about 33 per cent. less than that of the 1890 tincture.

Dose, fifteen to thirty minims (0.9 to 1.8 Cc.), or about fifty drops, to be gradually increased until some effects are experienced.

Off. Prep.—Tinctura Chloroformi et Morphine Composita, *Br.*

TINCTURA CANTHARIDIS. U. S., Br.

TINCTURE OF CANTHARIDES

(tinc-tū'ra cān'thār'-dīs)

Tincture of Spanish Flies; Teinture (alcoolé) de Cantharide, *Fr. Cod.*; Tinctura Cantharidum, *P. G.*; Spanischblagentinktur, *G.*; Tintura di cantaridi, *It.*; Tintura alcoholica de cantaridas, *Sp.*

* "Cantharides, in No. 60 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the Cantharides with *thirty-five cubic centimeters* [or 1 fluidounce, 88 minims] of Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it very firmly and pour on enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Alcohol to obtain *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

"Cantharides, in No. 40 powder, ¼ ounce (Imperial) or 12.5 grammes; Alcohol (90 per cent.), 1 pint (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

An improvement was made in this tincture in the 1880 revision by substituting alcohol for diluted alcohol. It is frequently used in mixtures of castor oil and alcohol in the so-called hair tonics, and when made with diluted alcohol turbidity results. The official tincture is double the strength of that of the U. S. P. 1890. It is the most convenient form for the internal use of Spanish flies, the virtues of which it possesses to their full extent. (See *Cantharis*.) If made with diluted alcohol, when long kept it deposits fatty matter, cantharidin in rhomboidal tables, and other crystals of a quite different form. (Ménière, *J. P. C.*, Avril, 1861, p. 289.) It is occasionally employed externally as a rubefacient; but its liability to vesicate should be taken into consideration. The British tincture is too feeble, containing the virtues of only 0.68 of a grain of cantharides in a fluidrachm.

Dose, of the U. S. tincture, two to five minims (0.12 to 0.3 Cc.), repeated three or four times a day.

TINCTURA CAPSICI. U. S., Br.

TINCTURE OF CAPSICUM

(tinc-tū'ra cāp'sī-çī)

Tincture of Cayenne Pepper; Teinture (alcoolé) de Piment des Jardins, *Fr.*; Tinctura capsici, *P. G.*; Spanischpfeffertinktur, *G.*

* "Capsicum, in No. 50 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *nine hundred and fifty cubic centimeters* [or 32 fluidounces, 59 minims] of Alcohol with *fifty cubic centimeters* [or 1 fluidounce, 331 minims] of Water. Moisten the Capsicum with *thirty-five cubic centimeters* [or 1 fluidounce, 88 minims] of the

menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms] of Tincture." *U. S.*

"Capsicum, in No. 20 powder, 1 ounce (Imperial) or 50 grammes; Alcohol (70 per cent.), 1 pint (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

This tincture is double the strength of that of the U. S. P. 1890. The alcoholic strength of the menstruum is of unusual proportions, 19 volumes of alcohol to 1 volume of water, the reason for this is that on account of oleoresinous constituents of capsicum alcohol is required and on account of a small quantity of a constituent soluble in water and insoluble in alcohol a little water must be added to the menstruum to prevent cloudiness. It is a useful stimulant in *very low states of the system* with gastric insensibility, as in *malignant scarlet* and *typhus fevers*, and in the cases of drunkards. It may also be used, diluted with water, as a gargle. (See *Capsicum*.) Applied by means of a camel's-hair pencil to the *relaxed uvula*, it sometimes produces contraction and relieves prolapsus of that part.

Dose, five to ten minims (0.3 to 0.6 Cc.).

Off. Prep.—Tinctura Chloroformi et Morphina Composita, *Br.*

TINCTURA CARDAMOMI. U. S.

TINCTURE OF CARDAMOM

(tinc-tŭ'ra cār-dā-mō'mi)

Telnture (alcoolé) de Cardamome, *Fr.*; Kardamomentinktur, *G.*

* "Cardamom, in No. 30 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Diluted Alcohol, a sufficient quantity, to make *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Moisten the Cardamom with *eighty cubic centimeters* [or 2 fluidounces, 338 minims] of Diluted Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Diluted Alcohol to obtain *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms] of Tincture." *U. S.*

The strength of this tincture was doubled in the U. S. P. (8th Rev.) in order to bring it into the 20 per cent. class; it is an agreeable but strong aromatic, and may be advantageously added to tonic and purgative infusions.

Dose, one-half to one fluidrachm (1.8 to 3.75 Cc.).

TINCTURA CARDAMOMI COMPOSITA.

U. S., *Br.*

COMPOUND TINCTURE OF CARDAMOM

(tinc-tŭ'ra cār-dā-mō'mi cōm-pōs'it-ā)

Telnture de Cardamome composée, *Fr.*; Zusammen-gesetzte Kardamomentinktur, *G.*

* "Cardamom, *twenty-five grammes* [or 386 grains]; Saigon Cinnamon, *twenty-five grammes* [or 386 grains]; Caraway, *twelve grammes* [or 185 grains]; Cochineal, *five grammes* [or 77 grains]; Glycerin, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Diluted Alcohol, a sufficient quantity, to make *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Mix the Glycerin with *nine hundred and fifty cubic centimeters* [or 32 fluidounces, 59 minims] of Diluted Alcohol. Reduce the Cardamom, Saigon Cinnamon, Caraway and Cochineal to a No. 40 powder, and macerate this powder in a stoppered container, in a moderately warm place, with *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of the menstruum during seven days, with occasional agitation; then filter through purified cotton, or a plain filter, and, when the liquid has drained off completely, pour on the residue, first the remainder of the menstruum, and then sufficient Diluted Alcohol to make *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms] of Tincture." *U. S.*

"Cardamom Seeds, bruised, $\frac{1}{2}$ ounce (Imperial) or 12.5 grammes; Caraway Fruit, bruised, $\frac{1}{2}$ ounce (Imp.) or 12.5 grammes; Raisins of commerce, freed from seeds, 2 ounces (Imp.) or 100 grammes; Cinnamon Bark, bruised, $\frac{1}{2}$ ounce (Imp.) or 25 grammes; Cochineal, in powder, 55 grains or 6.3 grammes; Alcohol (60 per cent.), 1 pint (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

The proportion of cardamom, cinnamon and caraway in the U. S. P. (8th Rev.) was increased to 25, 25, and 12 Gm. respectively; the U. S. P. 1890 proportion being 20, 20, and 10.

This is a very agreeable aromatic tincture, occasionally used as a carminative, but more frequently as an addition to mixtures, infusions, etc., which it renders pleasant to the taste and acceptable to the stomach. The substitution of honey in the U. S. formula of 1870 for the raisins in that of 1850 was an improvement, as it facilitated the process and gave more precision to the result; but a still greater improvement was made in the process of 1880

in the substitution of glycerin, which increases the stability of the preparation and takes the place of honey which is usually found adulterated in commerce.

Dose, one to two fluidrachms (3.75 to 7.5 Cc.).

Off. Prep.—Decoctum Aloes Compositum, *Br.*;
Mistura Sennæ Composita, *Br.*

TINCTURA CASCARILLÆ. *Br.*

TINCTURE OF CASCARILLA

(tinc-tū'ra cās-cā-ril'lae)

Tincture (alcoolé) de Cascarille, *Fr. Cod.*; Kasarilltinktur, *G.*

"Cascarilla, in No. 40 powder, 4 ounces (Imperial) or 200 grammes; Alcohol (70 per cent.), a sufficient quantity. Moisten the powder with three fluid ounces (Imp. meas.) or one hundred and fifty cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure one pint (Imp. meas.) or one thousand cubic centimetres." *Br.*

This tincture has the properties of cascarilla, but is seldom if ever used in this country.

Dose, from thirty minims to two fluidrachms (1.8 to 7.5 Cc.).

TINCTURA CHIRATÆ. *Br.*

TINCTURE OF CHIRATA

(tinc-tū'ra çhī-rā'tæ)

Tincture of Chiretta; Teinture (alcoolé) de Chirette, *Fr.*; Chirettatinktur, *G.*

"Chiretta, in No. 40 powder, 2 ounces (Imperial) or 100 grammes; Alcohol (60 per cent.), a sufficient quantity. Moisten the powder with two fluid ounces (Imp. meas.) or one hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure one pint (Imp. meas.) or one thousand cubic centimetres." *Br.*

This is a tonic tincture which was introduced for the first time by the U. S. P. 1880, but which even before then had been largely used in some sections of our country. It was dismissed by the U. S. P. (8th Rev.). The British tincture (1898) was decreased in strength 20 per cent., and is now uniform with the U. S. 1890 tincture.

Dose, from one to two fluidrachms (3.75 to 7.5 Cc.), three or four times a day.

TINCTURA CHLOROFORMI ET MORPHINÆ COMPOSITA. *Br.*

COMPOUND TINCTURE OF CHLOROFORM AND MORPHINE

(tinc-tū'ra çhlō-rō-fōr'mī ēt mōr-phī'næ cōm-pōs'it-ā)

"Chloroform, 1½ fl. ounces (Imperial measure) or 75 cubic centimetres; Morphine Hy-

drochloride, 87½ grains or 10 grammes; Diluted Hydrocyanic Acid, 1 fl. ounce (Imp. meas.) or 50 cubic centimetres; Tincture of Capsicum, ½ fl. ounce (Imp. meas.) or 25 cubic centimetres; Tincture of Indian Hemp, 2 fl. ounces (Imp. meas.) or 100 cubic centimetres; Oil of Peppermint, 14 minims or 1.5 cubic centimetres; Glycerin, 5 fl. ounces (Imp. meas.) or 250 cubic centimetres; Alcohol (90 per cent.), a sufficient quantity. Mix the Chloroform, Tincture of Capsicum, Tincture of Indian Hemp, Oil of Peppermint, and Glycerin with nine fluid ounces (Imp. meas.) or four hundred and fifty cubic centimetres of the Alcohol, and dissolve the Morphine Hydrochloride in the mixture; add the Diluted Hydrocyanic Acid; then mix with enough of the Alcohol to form one pint (Imp. meas.) or one thousand cubic centimetres of the Compound Tincture. This preparation contains in a ten-minim dose ½ minim of Chloroform, ½ minim of Diluted Hydrocyanic Acid, and 1-11th grain of Morphine Hydrochloride,—that is, more than four times the proportion of Morphine Hydrochloride present in the corresponding preparation of the British Pharmacopœia of 1885." *Br.*

This is the official substitute for chlorodyne, the well-known British nostrum. It not only differs in strength (see above) from the preparation formerly official, but is now transparent.¹ (See also *Chlorodyne*, p. 332.)

Dose, from five to fifteen minims (0.3 to 0.9 Cc.).

TINCTURA CIMICIFUGÆ. *U. S., Br.*

TINCTURE OF CIMICIFUGA

(tinc-tū'ra cīm-i-cif'ū-gæ)

Tinctura Actææ Racemose; Tinctura Actææ; Tincture of Actææ; Tincture of Black Cohosh, Tincture of Black Snakeroot; Teinture (alcoolé) d'Actææ à Grappes, *Fr.*; Cimicifugantinktur, *G.*

* "Cimicifuga, in No. 40 powder, two hundred grammes [or 7 ounces av., 24 grains]; Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the Cimicifuga with sixty cubic centimeters [or 2 fluidounces, 14 minims] of Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough Alcohol to saturate the powder and leave a stratum above

¹ *Tinctura Chloroformi et Morphine Composita, B. P., 1898—Improved Formula.*—W. Lyon considers it desirable that the formula for compound tincture of chloroform and morphine be so constructed as to resemble the 1885 preparation in appearance, and to be given in doses of 20 to 30 drops instead of 10 drop-doses. He finds that the following formula gives a reliable preparation, which does not separate, and is miscible with water: Chloroform, 60 Cc.; morphine hydrochloride, 5 Gm.; diluted hydrocyanic acid, 45 Cc.; tincture of Indian hemp, 30 Cc.; tincture of capsicum, 15 Cc.; oil of peppermint, 1 Cc.; mucilage of gum acacia, 120 Cc.; treacle, 240 Cc.; liquid extract of liquorice, 120 Cc.; glycerin, 210 Cc.; alcohol (90 per cent.), 154 Cc. or sufficient to produce 1 liter. (*P. J.*, June 21, 1902, 581.)

it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Alcohol to obtain *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms] of Tincture." *U. S.*

"*Cimicifuga*, in No. 40 powder, 2 ounces (Imperial) or 100 grammes; Alcohol (60 per cent.), a sufficient quantity. Moisten the powder with one fluid ounce (Imp. meas.) or fifty cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure one pint (Imp. meas.) or one thousand cubic centimetres." *Br.*

This tincture is inferior to the fluidextract, because the medicinal powers of the menstruum are almost equal to those of the drug, although dissimilar in therapeutic action. The strength of the British tincture (1898) was injudiciously decreased 20 per cent., and it is now only half that of the *U. S.* tincture.

Dose, from one to two fluidrachms (3.75 to 7.5 Cc.).

TINCTURA CINCHONÆ. *U. S.*, *Br.*

TINCTURE OF CINCHONA

(tinc-tŭ'ră cin-ŭhō'næ)

Tinctura Cinchonæ Flavæ: Tincture of Yellow Cinchona; Tincture of Peruvian Bark; Teinture (alcoolé) de Quinquina jaune, *Fr. Cod.*; Tinctura Chinæ, *P. G.*; Chinatinktur, *G.*; Tintura di china, *It.*

* "*Cinchona*, in No. 60 powder (yielding not less than 4 percent. of anhydrous ether-soluble alkaloids), two hundred grammes [or 7 ounces av., 24 grains]; Glycerin, seventy-five cubic centimeters [or 2 fluidounces, 257 minims]; Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Mix the Glycerin with six hundred and seventy-five cubic centimeters [or 22 fluidounces, 396 minims] of Alcohol and two hundred and fifty cubic centimeters [or 8 fluidounces, 218 minims] of Water. Moisten the Cinchona with eighty cubic centimeters [or 2 fluidounces, 338 minims] of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, pouring on first the remainder of the menstruum, and then sufficient of a mixture of Alcohol and Water, made in the same proportions as before, until one thousand cubic centimeters [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms] of percolate are obtained. Tincture of Cinchona, when assayed by the process given below, should contain in one hundred cubic centimeters 0.75 Gm. of anhydrous ether-soluble alkaloids of Cinchona." *U. S.*

An assay process was appended to the formula of this tincture in the *U. S. P.* (8th Rev.).

Assay. *U. S.* (8th Rev.).—"Transfer 50 Cc. of Tincture of Cinchona to an evaporating dish, and evaporate it on a water-bath until it measures about 10 Cc., transfer the liquid to a bottle having the capacity of about 180 Cc., rinsing the dish with 10 Cc. of diluted alcohol, then assay the resulting liquid by the method given under *Fluidextractum Cinchonæ* (page 533), with the exception that the multiplication of the product should be by 4 instead of 20; the result will represent the weight in grammes of anhydrous ether-soluble alkaloids contained in one hundred cubic centimeters of Tincture of Cinchona." *U. S.*

"Red Cinchona Bark, in No. 40 powder, 4 ounces (Imperial) or 200 grammes; Alcohol (70 per cent.), a sufficient quantity. Moisten the powdered Bark with four fluid ounces (Imp. meas.) or two hundred cubic centimetres of the Alcohol; set aside for twenty-four hours in a closed vessel; percolate with more of the Alcohol, until fourteen fluid ounces (Imp. meas.) or seven hundred cubic centimetres of percolate have been collected; press the marc; add the expressed liquid to the percolate; set aside for twenty-four hours; filter.

Take ten cubic centimetres of the resulting strong tincture, and determine its proportion of alkaloids by the assay process given under '*Extractum Cinchonæ Liquidum*.' [See page 533.]

Add to the bulk of the strong tincture such a quantity of the Alcohol that one hundred cubic centimetres of the resulting Tincture shall contain one gramme of alkaloids. Ten cubic centimetres, when treated by the assay process described under '*Extractum Cinchonæ Liquidum*,' should yield an amount of alkaloids representing not less than 0.95 gramme nor more than 1.05 grammes, in one hundred cubic centimetres of the Tincture." *Br.*

This tincture is very properly made with a large proportion of bark, as in the bitter tinctures it is important that the alcohol should bear as small a proportion to the tonic principle as possible. Even when strongest, however, it cannot, in ordinary cases, be given in doses sufficiently large to obtain the full effect of the bark, without stimulating too highly. The tincture of the *Br. Pharm.* 1898 is now made from 70 per cent. alcohol instead of the old menstruum 50 per cent., and is assayed so that it has a definite strength (100 Cc. containing 1 Gm. of alkaloids); these are undoubted improvements. (*C. D.*, 1892, 325.) A deposit is apt to form in the tincture when kept, consisting chiefly of cinchoninic red holding probably a portion of the alkaloids in combination. This was found by J. Adams to be perfectly dissolved by heat, though it uniformly reappeared on the cooling of the tincture. The addition of diluted sulphuric acid did not cause its solution, and, even though it was removed by filtering the tincture, the deposition

was afterwards renewed. (*P. J.*, April, 1868, 470.) In reference to a mode of obviating in some measure this tendency to deposition, the reader is referred to the statements of M. Vauffart on the subject of deposition in the tinctures prepared by percolation. A. B. Taylor, in experimenting on this subject, prepared a tincture in which the menstruum consisted of two parts of alcohol, one part of water, and one part of glycerin, and which was kept three months without undergoing deposition. (*A. J. P.*, Jan. 1865, 50.) This suggested the addition of glycerin to the official formula, and there can be no doubt that the tincture has been thereby improved, experience having demonstrated the utility of glycerin in liquid preparations of cinchona. Tincture of cinchona is rarely employed, but may be used as a tonic.

Dose, from one to two fluidrachms (3.75 to 7.5 Cc.).

Off. Prep.—Tinctura Cinchonæ Composita, *Br.*

TINCTURA CINCHONÆ COMPOSITA. U. S., *Br.*

COMPOUND TINCTURE OF CINCHONA

(tinc-tŭ'ra cîn-phō'næ cōm-pōs'it-tā)

Compound Tincture of Peruvian Bark; Huxham's Tincture of Bark; Teinture de Quinquina composée, Elixir fébrifuge d'Huxham, *Fr.*; Tinctura Chinæ Composita, *P. G.*; Zusammengesetzte Chinatinktur, *G.*

* "Red Cinchona (yielding not less than 5 percent. of anhydrous cinchona alkaloids), *one hundred grammes* [or 3 ounces av., 231 grains]; Bitter Orange Peel, *eighty grammes* [or 2 ounces av., 360 grains]; Serpentina, *twenty grammes* [or 309 grains]; Glycerin, *seventy-five cubic centimeters* [or 2 fluidounces, 257 minims]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *six hundred and seventy-five cubic centimeters* [or 22 fluidounces, 396 minims] of Alcohol and *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water. Reduce the Red Cinchona, Bitter Orange Peel and Serpentina to a No. 60 powder, moisten this powder with *eighty cubic centimeters* [or 2 fluidounces, 338 minims] of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, pouring on first the remainder of the menstruum, and then sufficient of a mixture of Alcohol and Water, made in the same proportions as before, to obtain *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

"Dried Bitter-Orange Peel, well bruised, 1 ounce (Imperial) or 50 grammes; Serpentina

Rhizome, in No. 40 powder, ½ ounce (Imp.) or 25 grammes; Cochineal, in powder, 28 grains or 3.2 grammes; Saffron, 55 grains or 6.3 grammes; Tincture of Cinchona, 10 fl. ounces (Imp. meas.) or 500 cubic centimetres; Alcohol (70 per cent.), *a sufficient quantity*. Mix the solid ingredients with *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Alcohol; set aside in a closed vessel for seven days, agitating frequently; strain; press the marc; mix the liquids; add the Tincture of Cinchona, and enough of the Alcohol to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Compound Tincture; set aside for twenty-four hours; filter. 10 cubic centimetres, when treated by the assay process described under 'Extractum Cinchonæ Liquidum' [page 533], should yield not less than 0.045 gramme nor more than 0.055 gramme of alkaloids. 2 cubic centimetres of the Compound Tincture after evaporation should leave a residue which imparts a yellow color to *chloroform*." *Br.*

This is the preparation commonly known by the name of *Huxham's tincture of bark*. It differs from that official in the U. S. P. 1890 only in the alcoholic strength of the menstruum, which is now about in the proportion of 2.7 volumes of alcohol to 1 volume of water; it was formerly 3 volumes of alcohol to 1 volume of water. The use of glycerin is an improvement, precipitation being thus largely prevented. It will be observed that the drugs are not directed in the powdered state, the intention being to mix the drugs together and then to reduce the mixture to a *uniform powder*; in this way the volatile principles in the Serpentina and Orange Peel are retained, and thorough exhaustion by percolation is secured. The process for the British tincture (1898) presents some novel features. Half of the quantity of the tincture is first made from four of the ingredients; this is then mixed with an equal bulk of tincture of cinchona. The reason for this was probably to avoid assaying a mixed product during the process; but the final test has to deal with the finished tincture, and the utility of the whole method is doubtful. The U. S. P. process uses assayed cinchona bark, but omits an assay of the finished tincture because the presence of the soluble principles from bitter orange peel and serpentina renders an assay process impracticable if not useless. Compound tincture of cinchona is an excellent stomachic cordial tonic, too feeble, however, in the principles of cinchona to serve as a substitute for the alkaloids when a full effect is required.

Dose, one to two fluidrachms (3.75 to 7.5 Cc.).

TINCTURA CINNAMOMI. U. S., *Br.*

TINCTURE OF CINNAMON

(tinc-tŭ'ra cîn-nā-mō'mī)

Teinture (alcoolé) de Cannelle, *Fr. Cod.*; Tinctura Cinnamomi, *P. G.*; Zimmtinktur, *G.*; Tintura alcoolica de canela, *Sp.*

* "Saigon Cinnamon, in No. 50 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Glycerin, *seventy-five cubic centimeters* [or 2 fluidounces, 257 minims]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *six hundred and seventy-five cubic centimeters* [or 22 fluidounces, 396 minims] of Alcohol and *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water. Moisten the Saigon Cinnamon with *eighty cubic centimeters* [or 2 fluidounces, 338 minims] of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on first the remainder of the menstruum, and then sufficient of a mixture of Alcohol and Water, made in the same proportions as before, to obtain *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

"Cinnamon Bark, in No. 40 powder, 4 ounces (Imperial) or 200 grammes; Alcohol (70 per cent.), *a sufficient quantity*. Moisten the powder with *four fluid ounces* (Imp. meas.) or two hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

The British tincture (1898) was increased 60 per cent. in the proportion of cinnamon. This tincture was doubled in strength in the U. S. P. (8th Rev.); it has the aromatic and astringent properties of cinnamon, and may be used as an adjuvant to cretaceous mixtures and astringent infusions or decoctions. By long keeping it is prone to gelatinize and become unfit for use. According to Greenish, this can be prevented by using a menstruum composed of six parts of alcohol and two parts of water. (*P. J.*, Feb. 1872, 641.)

Dose, one to four fluidrachms (3.75 to 15 Cc.). It is an agreeable flavoring to other tinctures.

TINCTURA COCCI. Br.

TINCTURE OF COCHINEAL

(tinc-tū'ra cōc'ci)

Teinture (alcoolé) de Cochenille, *Fr. Cod.*; Cochenilletinktur, *G.*

"Cochineal, in powder, 2 ounces (Imperial) or 100 grammes; Alcohol (45 per cent.), 1 pint (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

This is valued chiefly for imparting color to liquid preparations. It may, however, be given internally in nervous affections.

Dose, from twenty minims to a fluidrachm (1.3 to 3.75 Cc.).

TINCTURA COLCHICI SEMINIS.

U. S. (Br.)

TINCTURE OF COLCHICUM SEED

(tinc-tū'ra cōl'phī-cī sēm'j-nīs)

Tinctura Colchici Seminum, *Br.*; *Tinctura Colchici*, *U. S.* 1890; Teinture (alcoolé) de semence de Colchique, *Fr. Cod.*; *Tinctura Colchici*, *P. G.*; Zejtiosentinktur, *G.*; *Tintura alcoholica de colquico*, *Sp.*

* "Colchicum Seed, in No. 50 powder (containing not less than 0.55 percent. of colchicine), *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Water. Moisten the Colchicum Seed with *forty cubic centimeters* [or 1 fluidounce, 169 minims] of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of percolate. Tincture of Colchicum Seed, when assayed by the process given below, should contain in *one hundred cubic centimeters* 0.05 Gm. of colchicine." *U. S.*

Assay. *U. S.* (8th Rev.)—"Transfer 100 Cc. of Tincture of Colchicum Seed to an evaporating dish, and evaporate it on a water-bath until it measures about 10 Cc. Add, if necessary, sufficient alcohol to dissolve any separated substance, and then assay the resulting liquid by the method given under *Fluidextractum Colchici Seminis* (page 535), with the exception that the multiplication of the product by 10 be omitted; the result will represent the weight in grammes of colchicine contained in *one hundred cubic centimeters* of Tincture of Colchicum Seed." *U. S.*

"Colchicum Seeds, in No. 30 powder, 4 ounces (Imperial) or 200 grammes; Alcohol (45 per cent.), *a sufficient quantity*. Moisten the powder with *two and a half fluid ounces* (Imp. meas.) or one hundred and twenty-five cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres. This preparation is made with rather more than one and a half times the proportion of Colchicum Seeds ordered for the corresponding preparation in the British Pharmacopœia of 1855." *Br.*

The strength of this tincture was lowered to 10 per cent. in the U. S. P. (8th Rev.) to

comply with the rule adopted for potent tinctures (see page 1293). An assay process was also appended.

It was at one time supposed that the tincture was quite as effective made from the unbruised as from the bruised seeds, but the opinion has been shown to be erroneous. (*A. J. P.*, xxvi. 120.) See also a paper by N. Rosenwasser, *Ibid.*, 1877, 436. Subsequently L. I. Morris showed that if the whole seeds were *digested* with hot diluted alcohol they could be perfectly exhausted. (*A. J. P.*, 1881, p. 6.) Maisch recommended, as a convenient method of comminuting the seeds, to macerate them for two or three days in a portion of the menstruum, then to remove them and bruise them in a clean iron mortar, taking care that none of the menstruum or of the seeds should be wasted. (*Ibid.*, xxviii. 514.)

This tincture possesses the properties of colchicum, and may be given whenever that medicine is indicated, but the wine, containing less alcohol, is generally preferred.

Dose, from fifteen to thirty minims (0.9 to 1.8 Cc.), to be repeated with caution.

TINCTURA CONII. Br.

TINCTURE OF CONIUM

(tinc-tū'ra cō-nī'i)

Tinctura Conii Fructus. *Br.* 1874: Tincture of Hemlock Fruit; Teinture (alcoolé) de Ciguë (feuille), *Fr. Cod.*; Schierlingstinktur, *G.*

"Conium Fruit, recently reduced to No. 40 powder, 4 ounces (Imperial) or 200 grammes; Alcohol (70 per cent.), a sufficient quantity. Moisten the powder with four fluid ounces (Imp. meas.) or two hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure one pint (Imp. meas.) or one thousand cubic centimetres." *Br.*

This tincture was not admitted to the U. S. P. 1890; the formula of the tincture official in 1880 is appended.¹ The British tincture (1898) was increased 60 per cent. in strength over the tincture of the *Br. Ph.* 1885. A strong odor of conine should be emitted by the tincture upon the addition of an alkali. *Ménière* states that it lets fall, on standing, a yellow milary deposit, resembling drops of oil, the form of which is modified under pressure. According to the experiments of John Harley of London (*P. J.*, Jan. 1867, 414), the British tincture is an uncertain preparation, two fluidounces of it sometimes failing to produce any effect. The

U. S. P. 1880 tincture was, however, about 30 per cent. stronger than the British, and cannot be considered inert if care be taken to select the conium fruit properly.

Commencing *dose*, thirty minims (1.8 Cc.), to be increased if necessary.

TINCTURA CROCI. Br.

TINCTURE OF SAFFRON

(tinc-tū'ra crō'cī)

Teinture (alcoolé) de Safran, *Fr. Cod.*; Safran-tinktur, *G.*

"Saffron, 1 ounce (Imperial) or 50 grammes; Alcohol (60 per cent.), one pint (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

Tincture of saffron was official in the U. S. P. 1890.¹ This tincture possesses all the properties of saffron, but is of little other use than to give color to mixtures.

Dose, from one to three fluidrachms (3.75 to 11.25 Cc.).

TINCTURA CUBEBÆ. Br.

TINCTURE OF CUBEÆ

(tinc-tū'ra cū-bē'bæ)

Tincture of Cubebs; Teinture (alcoolé) de Cubèbe, *Fr. Cod.*; Kubebentinktur, *G.*

"Cubebs, in powder, 4 ounces (Imperial) or 200 grammes; Alcohol (90 per cent.), a sufficient quantity. Moisten the powder with two fluid ounces (Imp. meas.) or one hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure one pint (Imp. meas.) or one thousand cubic centimetres." *Br.*

The U. S. P. 1880 tincture was about 25 per cent. weaker than that of the U. S. P. 1870, a change which was very unfortunate, almost destroying any therapeutic value the preparation may have had. The U. S. P. 1890 tincture, which is double the strength of the former tincture, undoubtedly represents cubeb.² Its usefulness was not sufficient, however, to warrant its being retained in the present Pharmacopœia. The British tincture (1898) is 60 per cent.

¹ "Saffron, one hundred grammes [or 3 ounces av., 231 grains]; Diluted Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluid-ounces, 6½ fluidrachms]. Moisten the Saffron with one hundred cubic centimeters [or 3 fluidounces, 183 minims] of Diluted Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Diluted Alcohol upon it, until one thousand cubic centimeters [or 33 fluid-ounces, 6½ fluidrachms] of Tincture are obtained." *U. S.* 1890.

² "Cubeb, in No. 30 powder, two hundred grammes [or 7 ounces av., 24 grains]; Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with one hundred cubic centimeters [or 3 fluid-ounces, 183 minims] of Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Alcohol upon it, until one thousand cubic centimeters [or 33 fluid-ounces, 6½ fluidrachms] of Tincture are obtained." *U. S.* 1890.

¹ "Conium, in No. 30 powder, one hundred and fifty parts [or four and three-quarter ounces av.]; Diluted Hydrochloric Acid, four parts [or one fluidrachm]; Diluted Alcohol, a sufficient quantity, to make one thousand parts [or two pints]. Moisten the powder with forty-five parts [or two fluidounces] of Diluted Alcohol, previously mixed with the Diluted Hydrochloric Acid, and macerate for twenty-four hours; then pack it moderately in a conical glass percolator, and gradually pour Diluted Alcohol upon it, until one thousand parts [or two pints] of tincture are obtained." *U. S.* 1880.

stronger than the one formerly official, and is now identical with the U. S. P. 1890 preparation.

Dose, one to two fluidrachms (3.75 to 7.5 Cc.).

TINCTURA DIGITALIS. U. S., Br.

TINCTURE OF DIGITALIS

(tinc-tū'ra dig-i-tāl'is)

Tincture of Foxglove; Teinture (alcoolé) de Digitale, *Fr. Cod.*; Tinctura Digitalis, *P. G.*; Fingerhüt-tinktur, *G.*; Tintura di digitale, *It.*; Tintura alcoolica de digital, *Sp.*

* "Digitalis, in No. 60 powder, one hundred grammes [or 3 ounces av., 231 grains]; Diluted Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the Digitalis with forty cubic centimeters [or 1 fluidounce, 169 minims] of Diluted Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

"Digitalis Leaves, in No. 20 powder, 2½ ounces (Imperial) or 125 grammes; Alcohol (60 per cent.), a sufficient quantity. Moisten the powder with two fluid ounces (Imp. meas.) or one hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure one pint (Imp. meas.) or one thousand cubic centimetres." *Br.*

In preparing this tincture, great attention should be paid to the selection of the leaves, according to the rules laid down under the head of *Digitalis*. From a neglect of these it is likely to be weak or inefficient. C. Focke (*Deutsche Aerzte Zeitung*) recommends keeping tincture of digitalis protected from the light. The expressed juice of the leaves, preserved by means of alcohol, prepared as the British *Succi*, would probably be found to be a useful preparation. (See page 1199.) Tincture of digitalis possesses all the virtues of that drug, and affords a convenient method of administering it, especially in mixtures. It is said by Ménière to deposit on standing a green oily matter, and some white lance-shaped crystals soluble in an excess of acid. (*J. P. C.*, Avril, 1861, p. 289.) The present U. S. preparation is weaker (one-third) than that of the U. S. P. 1890.¹

¹ Fat-free tincture of digitalis is recommended by J. W. England (*Proc. Penna. Pharm. Assoc.*, 1899, 158). It is made by exhausting the leaves, freshly ground to a No. 60 powder, with purified petroleum benzol, either by maceration, or by maceration and percolation, as may be most convenient. The residue is then dried to remove all odor of benzol, the best results being obtained by exposure to the sunlight as well as air. The tincture is then made by the

Dose, from ten to thirty minims (0.6 to 1.8 Cc.), repeated two or three times a day, and increased if necessary, but with caution; a fluidrachm, representing about six grains of digitalis, may be given on occasion as a single dose.

TINCTURA ERGOTÆ AMMONIATA. Br.

AMMONIATED TINCTURE OF ERGOT

(tinc-tū'ra ĕr'gō-tæ am-mō-ni-ā'ta)

Tinctura Secalis Cornuti Ammoniata; Teinture Ammoniacale de Seigle Ergoté, *Fr.*; Ammoniakalische Mutterkorn-tinktur, *G.*

"Ergot, in No. 20 powder, 5 ounces (Imperial) or 250 grammes; Solution of Ammonia, 2 fl. ounces (Imp. meas.) or 100 cubic centimetres; Alcohol (60 per cent.), a sufficient quantity. Mix the Solution of Ammonia with eighteen fluid ounces (Imp. meas.) or nine hundred cubic centimetres of the Alcohol; moisten the powder with two fluid ounces (Imp. meas.) or one hundred cubic centimetres of this mixture, and percolate with the remainder; press the marc; mix the expressed liquid with the percolate; add enough of the Alcohol to form one pint (Imp. meas.) or one thousand cubic centimetres of the Tincture; set aside for twenty-four hours; filter." *Br.*

This is a new official tincture of the Br. Ph. 1898; it differs from the tincture recommended by the British Pharmaceutical Conference in the use of solution of ammonia in place of aromatic spirit of ammonia.

Dose, from one-half to one fluidrachm (1.8 to 3.75 Cc.).

TINCTURA FERRI CHLORIDI.

U. S. (Br.)

TINCTURE OF FERRIC CHLORIDE

(tinc-tū'ra fēr'rī chlō'rī-di)

"A hydro-alcoholic solution of Ferric Chloride [$\text{FeCl}_3 = 161.04$] containing not less than 13.28 percent. of the anhydrous salt, corresponding to 4.6 (4.58) percent. of metallic iron." *U. S.*

Tinctura Ferri Perchloridi, Br.; Tincture of Chloride of Iron; Tinctura Ferri Muriatis; Tincture of Perchloride of Iron; Tincture of Muriate of Iron; Tinctura Ferri Sesquichloridi; Teinture de Perchlorure de Fer, *Fr.*; Eisenchlorid-tinktur, *G.*

* "Solution of Ferric Chloride, three hundred and fifty cubic centimeters [or 11 fluidounces, 401 minims]; Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix the Solu-

official process from 100 grammes (original weight of the powder), with this difference that only 980 Cc. of percolate instead of 1000 Cc. are obtained. Ammonia water is then carefully added to neutralization, for which from 10 to 15 Cc. are required, and the final measure is made up with diluted alcohol to 1000 Cc. The product is a deep reddish-brown, almost black liquid, of a not unpleasant odor and pure bitter taste, free from the acidity of the official tincture (see also Scoville's paper, *D. C.*, 1904, 93).

tion with enough Alcohol to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Let the Tincture stand, in a closely covered vessel, protected from light, at least three months; then transfer it to glass-stoppered bottles, and keep it protected from light.”

U. S.

“Strong Solution of Ferric Chloride, 5 fl. ounces (Imperial measure) or 250 cubic centimetres; Alcohol (90 per cent.), 5 fl. ounces (Imp. meas.) or 250 cubic centimetres; Distilled Water, a *sufficient quantity*. Mix the Strong Solution of Ferric Chloride with the Alcohol; add sufficient Distilled Water to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture.” Br.

This tincture does not differ materially from that official in 1880, the change due to making one by weight and the other by volume, and the rounding of the figures, causing a difference in specific gravity,—the U. S. P. 1880 tincture having the sp. gr. 0.980 and the U. S. P. 1890 tincture that of 0.960, the latter thus being slightly weaker. In the U. S. P. (8th Rev.) the quantity of Solution of Ferric Chloride, used in making 1000 Cc. of the tincture, is increased from 250 Cc. to 350 Cc. on account of the reduction in strength of the solution from 13 per cent. of metallic iron to 10 per cent. The strength of the new tincture, in ferric chloride, remains practically the same as the 1890 preparation.

The U. S. formula of 1870 appeared, in respect to the precise method of proceeding, to be copied from that of E. R. Squibb, published in *A. J. P.* (1857, p. 290).¹ Iron wire was chosen as the form of iron to be used, because it is generally the purest. This, which was in very slight excess, was first treated with a portion of the hydrochloric acid, which formed with it ferrous chloride, with the escape of hydrogen, producing effervescence. The action was allowed to go on spontaneously until effervescence ceased, and was then aided by heat, which caused the saturation of the acid used. The solution being filtered, the remainder of the hydrochloric acid was added, and afterwards the nitric acid gradually, the liquid having been heated to the boiling point before the latter addition. The nitric acid was decomposed, with the escape of nitrous fumes producing effervescence, while, through the influence of a portion of its oxygen and the additional portion of hydrochloric acid, the ferrous chloride was converted into ferric chloride, the conversion being completed when the effervescence ceased and the previous green color had been changed to a reddish brown. The precise reactions by which these changes are effected have been explained elsewhere. (See *Ferri Chloridum*, page 494, and *Liquor Ferri Chloridi*, page 713.) In the revision of 1870 the process was divided into two parts, and a new preparation, *Liquor Ferri Chloridi*, intro-

duced. When this is added to the alcohol, the latter reacts gradually with the acid, producing a small proportion of an ether which gives a peculiar flavor to the tincture and probably modifies in some degree its influence on the system. For this reason it is preferable to keep the tincture a year before dispensing, and the official direction is to keep it at least three months.

Properties.—Tincture of ferric chloride is officially described as “a bright, brownish liquid, having a slightly ethereal odor, a very astringent styptic taste, and an acid reaction. Specific gravity: about 1.005 at 25° C. (77° F.). The Tincture yields a brownish-red precipitate with ammonia water, a blue one with potassium ferrocyanide T.S., and a white one, insoluble in nitric acid, with silver nitrate T.S. After the Tincture has been exposed for some time to daylight, it yields a greenish or greenish-blue color with potassium ferrocyanide T.S., showing the presence of some ferrous salt, due to reduction. On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and a diluted portion of the Tincture (1 in 10), the crystal should not become colored brown, nor should there be a brownish-black zone developed around it (absence of *nitric acid*). Evaporate 2.22 Gm. of the Tincture to dryness on a water-bath, add 2 Cc. of hydrochloric acid and 5 Cc. of solution of hydrogen dioxide, and again evaporate the mixture to dryness; dissolve the residue in 10 Cc. of water, pour the solution into a glass-stoppered bottle having a capacity of about 100 Cc., rinsing the vessel with 10 Cc. more of water, add 1 Cc. of hydrochloric acid and 1 Gm. of potassium iodide, and keep the mixture for half an hour at a temperature of 40° C. (104° F.), then cool and add a little starch T.S.; it should require not less than 18.3 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the blue color of the liquid (each Cc. of the volumetric solution used indicating 0.25 percent. of metallic iron).” U. S.² The tincture is decomposed by the alkalies, alkaline earths and their carbonates, astringent vegetable infusions, and mucilage of acacia, which produces with it a brown semi-transparent jelly. All these substances are, therefore, incompatible with it in prescriptions.³

² J. C. Wharton has noticed in the tincture silky asbestos-like crystals, which he believes are due to an action of the acids upon the glass in which the drug is prepared. (*A. J. P.*, xlii. 107.) Dr. Battey believes these crystals to be calcium sulphate. (*Ibid.*, xlii. 207.)

³ *Bestuchef's tincture*, which is much used in Europe, is simply a solution of ferric chloride in a mixture of one measure of ether and three or four measures of alcohol. Fr. Mayer recommends that the ferric chloride should be prepared by passing chlorine through a solution of ferrous chloride, until a solution of potassium ferrocyanide no longer produces a blue precipitate, and then evaporating by a water-bath. In this mode crystals of ferric chloride are obtained, one ounce of which is to be dissolved in twelve ounces of ether mixed with four times its bulk of alcohol. The solution may be rendered colorless, if desired, by exposure to the direct rays of the sun. (*N. Y. J. Pharm.*, 1. 253.) This decolorization, however, is effected by a chemical change which somewhat alters

¹ This process of Squibb was given in a note in the eleventh edition of the U. S. Dispensatory, page 1052.

Uses.—This is one of the most active and certain preparations of iron, usually acceptable to the stomach, and much employed for the purposes to which the chalybeates generally are applied. It is somewhat diuretic, and acts as a slightly stimulant astringent upon the genito-urinary organs. It is very valuable in connection with tincture of cantharides in *gleet*, and is very largely used in *chronic Bright's disease*. In passive hemorrhages from the uterus, kidneys, and bladder it has been thought to act advantageously. It is the standard remedy in *erysipelas*; but in *scarlatina*, *diphtheria*, and *purulent infection of the blood*, experience has shown it to be of very little value, and as a styptic it is inferior to the solution of the sulphate. In acute febrile diseases, as *erysipelas*, the dose should be repeated every two hours. It should be given well diluted, and taken through a glass tube as it is very prone to injure the teeth.

Dose, five to thirty minims (0.3 to 1.8 Cc.), which may be gradually increased.

Off. Prep.—Liquor Ferri et Ammonii Acetatis, U. S.

TINCTURA GALLÆ. U. S.

TINCTURE OF NUTGALL

(tinc-tū'ra gāl'læ)

Tinctura Gallarum, *P. G.*; Tincture of Galls; Teinture (alcoolé) de Noix de Galle, *Fr.*; Gallapfetinktur, *G.*

*“Nutmeg, in No. 40 powder, two hundred grammes [or 7 ounces av., 24 grains]; Glycerin, one hundred cubic centimeters [or 3 fluidounces, 183 minims]; Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with nine hundred cubic centimeters [or 30 fluidounces, 208 minims] of Alcohol. Introduce the Nutgall, without moistening it, into a glass percolator, shaking down the pow-

der character of the preparation. The ferric chloride becomes ferrous chloride by the loss of a portion of its chlorine, which, by abstracting hydrogen from the alcohol, becomes hydrochloric acid; and this reacts with unaltered alcohol to form ethyl chloride.

A. Cushman recommends the following process for the above tincture: He first prepares the crystals of the sesquichloride by dissolving two ounces of iron filings in a mixture of eight fluidounces of hydrochloric acid and four of distilled water, then adding four fluidrachms of nitric acid, evaporating to a pellicle, and setting aside to crystallize. The crystals, having been washed in alcohol, and afterwards redissolved and crystallized, are to be dissolved in a mixture of two parts of alcohol and one of ether, the proportion being an ounce of the crystals to twelve fluidounces of the mixture. After solution, the liquid is to be filtered, and exposed for 48 hours to the direct rays of the sun. (*A. J. P.*, xxix. 461; from *Am. Med. Gaz.*)

Tasteless Tincture of Ferric Chloride.—J. Creuse introduced this preparation. We have used the following formula for it: Solution of Ferric Chloride, U. S. P., 1 fluidounce; Citric Acid, 544 grains; Sodium Carbonate, 1000 grains, or q. s.; Water, distilled, 1 fluidounce; Alcohol, q. s. Dissolve the citric acid in the distilled water, and heat to the boiling point, gradually adding the sodium carbonate until the acid is saturated. Mix this with the iron solution, which will now assume a beautiful green color, and make up the measure to 4 fluidounces with alcohol.

der evenly and compactly, and pour on sufficient of the menstruum to saturate it and leave a stratum above it. Allow the percolation to proceed slowly, pouring on the remainder of the menstruum, and then sufficient Alcohol to obtain one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Tincture.” U. S.

The tincture of galls is powerfully astringent, but is more used as a test than as a medicine. The present official tincture is about one-third stronger than that of the U. S. P. 1870. When long kept, it ceases to evince the reactions of tannic acid, in consequence of the conversion of this into gallic acid.

Dose, from one to three fluidrachms (3.75 to 11.25 Cc.).

TINCTURA GAMBIR COMPOSITA.

U. S. (Br.)

COMPOUND TINCTURE OF GAMBIR

[To replace Tinctura Catechu Composita, Pharm. 1890, Compound Tincture of Catechu]

(tinc-tū'ra gām'bīr cōm-pōs'it-ā)

Tinctura Catechu, *Br.*; Tincture of Catechu; Teinture (alcoolé) de Cachou, *Fr. Cod.*; Tinctura Catechu, *P. G.*; Katechutinktur, *G.*

*“Gambir, in No. 50 powder, fifty grammes [or 1 ounce av., 334 grains]; Saigon Cinnamon, in No. 50 powder, twenty-five grammes [or 386 grains]; Diluted Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Macerate the Gambir and Saigon Cinnamon in a stoppered container, in a moderately warm place, with seven hundred and fifty cubic centimeters [or 25 fluidounces, 173 minims] of Diluted Alcohol during forty-eight hours, with frequent agitation; then filter through purified cotton, or a plain filter, and, when the liquid has drained off completely, pass enough menstruum through the residue to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Tincture.” U. S.

“Catechu, in coarse powder, 4 ounces (Imperial) or 200 grammes; Cinnamon Bark, bruised, 1 ounce (Imp.) or 50 grammes; Alcohol (60 per cent.), 1 pint (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process.” *Br.*

The name of this tincture was changed at the 1880 revision, so that it more accurately indicated its composition than did its former name. In the U. S. P. (8th Rev.) the name was again changed to Tinctura Gambir Composita. This was due to the introduction of gambir in place of catechu (see *Gambir*). The present tincture is one-half the strength of the U. S. P. 1890 compound tincture of catechu. Cinnamon has been present in the tincture of catechu of former Pharmacopœias in the same relatively large proportion,—2 parts of cinnamon to 3 parts of catechu,—and this disproportion has been usually overlooked. The

present tincture contains 2 parts of gambir to 1 part of cinnamon. The British tincture (1898) was increased 60 per cent. in the proportion of catechu, and is now four times the strength of the U. S. tincture. This is a grateful astringent tincture, useful in all cases to which catechu is applicable and in which small quantities of spirit are not objectionable. It may often be advantageously added to cretaceous mixtures in *diarrhæa*. It may be given with sweetened water or some mucilaginous liquid, or in port wine when this is not contraindicated. It sometimes gelatinizes when kept, and becomes unfit for use.

Dose, of the U. S. tincture of gambir, two to four fluidrachms (7.5 to 15 Ce.); of the British tincture of catechu, one-half to two fluidrachms (1.8 to 7.5 Ce.).

TINCTURA GELSEMII. U. S. (Br.)

TINCTURE OF GELSEMIUM

(tinc-tŭ'ra gəl-sēm'ī-i)

Teinture (alcoolé) de Gelsemium, *Fr.*; Gelsemium-tinktur, *G.*

* "Gelsemium, in No. 60 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *six hundred and fifty cubic centimeters* [or 21 fluidounces, 470 minims] of Alcohol with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of Water. Moisten the Gelsemium with *thirty-five cubic centimeters* [or 1 fluidounce, 88 minims] of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

"Gelsemium Root, in No. 40 powder, *2 ounces* (Imperial) or 100 grammes; Alcohol (60 per cent.), *a sufficient quantity*. Moisten the powder with *one fluid ounce* (Imp. meas.) or fifty cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This tincture has proven a valuable addition, and will be preferred to the fluidextract for internal administration, as it is safer, and can be used more satisfactorily in extemporaneous combination. The menstruum of the U. S. P. 1890 and (8th. Rev.) processes is weaker than that formerly official, alcohol having been replaced by alcohol diluted with water in the proportion of 65 to 35. The strength of the

U. S. P. (8th Rev.) is one-third less than that of the U. S. P. 1890. For Farr and Wright's method of estimating this tincture, see *C. D.*, 1892, 263.

Dose, from ten to twenty minims (0.6 to 1.3 Ce.).

TINCTURA GENTIANÆ COMPOSITA.

U. S., Br.

COMPOUND TINCTURE OF GENTIAN

(tinc-tŭ'ra gĕn-tī-ā'næ cōm-pōs'ī-tə)

Teinture (alcoolé) de Gentiane Composée, *Fr.*; Zusammengesetzte Enziantinktur, *G.*

* "Gentian, *one hundred grammes* [or 3 ounces av., 231 grains]; Bitter Orange Peel, *forty grammes* [or 1 ounce av., 180 grains]; Cardamom, *ten grammes* [or 154 grains]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Water. Reduce the Gentian, Bitter Orange Peel and Cardamom to a No. 40 powder, moisten this powder with *sixty cubic centimeters* [or 2 fluidounces, 14 minims] of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for twelve hours; then pack it moderately and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twelve hours; then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

"Gentian Root, cut small and well bruised, *2 ounces* (Imperial) or 100 grammes; Dried Bitter-Orange Peel, well bruised, *¼ ounce* (Imp.) or 37.5 grammes; Cardamom Seeds, bruised, *¼ ounce* (Imp.) or 12.5 grammes; Alcohol (45 per cent.), *1 pint* (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

An improvement has been made in the process for this tincture, in directing the drugs to be mixed and powdered together; the pulverization is facilitated, and the odorous principles of the cardamom and orange peel are absorbed by the gentian. As compared with the U. S. P. 1880 tincture, the menstruum has been strengthened slightly, three volumes of alcohol and two of water being used in place of diluted alcohol, making a more permanent tincture; the proportion of cardamom has been reduced one-half, and that of gentian slightly increased. This is an elegant bitter, much used in *dyspepsia*, and as an addition to tonic mixtures in

debilitated states of the digestive organs or of the system generally. There is, however, much danger of its abuse, especially in chronic cases.

Dose, one or two fluidrachms (3.75 to 7.5 Cc.).

TINCTURA GUAIACI. U. S.

TINCTURE OF GUAIAIC

(tinc-tū'ra gwaī'a-cl)

Tinctura Guaiaci; Teinture (alcoolé) de Résine de Gayac, *Fr.*; Guajak tinktur, *G.*

* "Guaiac, in No. 40 powder, two hundred grammes [or 7 ounces av., 24 grains]; Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Macerate the Guaiac in a stoppered container, in a moderately warm place, with seven hundred and fifty cubic centimeters [or 25 fluidounces, 173 minims] of Alcohol during three days, with frequent agitation; then filter, and when the liquid has drained off, pour on enough Alcohol to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

Although this tincture can be prepared by percolation if care and skill are used, maceration is doubtless preferable.

This tincture is given in *chronic rheumatism* and *gout*, in the dose of from one to three fluidrachms three or four times a day. As it is decomposed by water, it is most conveniently administered in mucilage, sweetened water, or milk, by which the separated guaiac is held in temporary suspension. The following is a form of tincture of guaiac which Dewees found very efficient in the cure of *suppression of the menses* and *dysmenorrhœa*. "Take of the best Guaiac, in powder, four ounces; Carbonate of Soda or of Potassa one drachm and a half; Pimenta, in powder, an ounce; Diluted Alcohol a pint. Digest for a few days." Dewees directed a drachm or two of the spirit of ammonia to be added, *pro re nata*, to four fluidounces of the tincture. (*Treatise on Diseases of Females*, 1826, page 81.) The quantity of alkaline addition is too small to produce any other effect than to render the resin more soluble, while the pimenta can act only as a spice; so that the virtues of the tincture reside in the guaiac, and the official ammoniated tincture is probably equally effectual. Schär recommends tincture of guaiac as a reagent to detect the presence of ozonizing bodies. (*Ph. Rund.*, 1894, 254.)

Dose, one fluidrachm (3.75 Cc.) three times a day.

TINCTURA GUAIACI AMMONIATA.

U. S., Br.

AMMONIATED TINCTURE OF GUAIAIC

(tinc-tū'ra gwaī'a-cl am-mō-nī-ā'ta)

Tinctura Guaiaci Composita; Teinture (alcoolé) de Gayac ammoniacale, *Fr.*; Ammoniakalische Guajak tinktur, *G.*

* "Guaiac, in No. 40 powder, two hundred grammes [or 7 ounces av., 24 grains]; Aromatic Spirit of Ammonia, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Macerate the Guaiac in a stoppered container, in a moderately warm place, with seven hundred and fifty cubic centimeters [or 25 fluidounces, 173 minims] of Aromatic Spirit of Ammonia during three days, with frequent agitation; then filter, and, when the liquid has drained off, pour on enough Aromatic Spirit of Ammonia to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

"Guaicum Resin, in powder, 4 ounces (Imperial) or 200 grammes; Oil of Nutmeg, 30 minims or 3.1 cubic centimetres; Oil of Lemon, 20 minims or 2.1 cubic centimetres; Strong Solution of Ammonia, 1½ fl. ounces (Imp. meas.) or 75 cubic centimetres; Alcohol (90 per cent.), a sufficient quantity. Mix the Strong Solution of Ammonia with sixteen fluid ounces (Imp. meas.) or eight hundred cubic centimetres of the Alcohol; add the Guaicum Resin; set aside in a closed vessel for forty-eight hours, shaking frequently; filter; dissolve the Oil of Lemon and Oil of Nutmeg in the filtrate, and pass sufficient of the Alcohol through the filter to produce one pint (Imp. meas.) or one thousand cubic centimetres of the Tincture." *Br.*

The British Pharmacopœia 1898 improved the process for this tincture by abandoning the distilled aromatic spirit of ammonia used as a menstruum by the former British authority and substituting alcohol containing solution of ammonia and volatile oils, the proportion of oil of lemon having been reduced 60 per cent.

This tincture is celebrated in the treatment of *chronic rheumatism*, and is frequently also used in *amenorrhœa*. It is more stimulating, and is probably more effectual, than the preceding on account of the presence of the alkali. It is precipitated by water, and should be administered emulsified with gum, so that the guaiac be held in suspension.

Dose, from one to two fluidrachms (3.75 to 7.5 Cc.).

TINCTURA HAMAMELIDIS. Br.

TINCTURE OF HAMAMELIS

(tinc-tū'ra hām-a-mēl'i-dīs)

Teinture (alcoolé) de Hamamélis, *Fr.*; Hamamelis tinktur, *G.*; Tintura alcoholica de hamamelis, *Sp.*

"Hamamelis Bark, in No. 20 powder, 2 ounces (Imperial) or 100 grammes; Alcohol (45 per cent.), a sufficient quantity. Moisten the powder with one fluid ounce (Imp. meas.) or fifty cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure one pint (Imp. meas.) or one thousand cubic centimetres." *Br.*

Dose, from thirty to sixty minims (1.8 to 3.75 Cc.).

TINCTURA HYDRASTIS. U. S., Br.

TINCTURE OF HYDRASTIS

(tinc-tū'ra hŷ-drās'tis)

Teinture (alcoolé) de Hydrastis, *Fr.*; Hydrastis-tinktur, *G.*; Tintura alcoholica de hidrastis, *Sp.*

* "Hydrastis, in No. 60 powder (containing not less than 2.5 percent. of hydrastine), two hundred grammes [or 7 ounces av., 24 grains]; Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix Alcohol and Water in the proportion of six hundred and fifty cubic centimeters [or 21 fluidounces, 470 minims] of Alcohol and three hundred and fifty cubic centimeters [or 11 fluidounces, 401 minims] of Water. Moisten the Hydrastis with sixty cubic centimeters [or 2 fluidounces, 14 minims] of the menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, gradually adding menstruum until one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of percolate are obtained. Tincture of Hydrastis, when assayed by the process given below, should contain in one hundred cubic centimeters 0.4 Gm. of hydrastine." *U. S.*

Assay. *U. S.* (8th Rev.).—"Transfer 100 Cc. of Tincture of Hydrastis to an evaporating dish, and evaporate it on a water-bath until the liquid measures about 10 Cc. If any insoluble matter has separated, add sufficient alcohol to dissolve it, and then assay the resulting liquid by the method given under *Fluidextractum Hydrastis* (page 545), using the same details as there directed for 10 Cc. of Fluidextract of Hydrastis, with the exception that the weight of the residual alkaloids must be multiplied by 2 instead of by 20 as there directed, to give the weight in grammes of hydrastine contained in one hundred cubic centimeters of Tincture of Hydrastis." *U. S.*

"Hydrastis Rhizome, in No. 60 powder, 2 ounces (Imperial) or 100 grammes; Alcohol (60 per cent.), a sufficient quantity. Moisten the powder with two fluid ounces (Imp. meas.) or one hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure one pint (Imp. meas.) or one thousand cubic centimetres." *Br.* The British tincture is half the strength of that of the *U. S. P.* (8th Rev.).

This tincture will probably prove useful in combination with other tinctures, or as an addition to extemporaneous mixtures where the fluidextract would not be so eligible.

Dose, from one to two fluidrachms (3.75 to 7.5 Cc.).

TINCTURA HYOSCYAMI. U. S., Br.

TINCTURE OF HYOSCYAMUS

(tinc-tū'ra hŷ-qs-cŷ'a-mī)

Tincture of Henbane; Teinture (alcoolé) de Jusquiamme, *Fr.*; Blisenkrauttinktur, *G.*; Tintura alcoholica de beleno, *Sp.*

* "Hyoscyamus, in No. 60 powder (containing not less than 0.08 percent. of mydriatic alkaloids), one hundred grammes [or 3 ounces av., 231 grains]; Diluted Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the Hyoscyamus with forty cubic centimeters [or 1 fluidounce, 169 minims] of Diluted Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, gradually adding Diluted Alcohol until one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] are obtained. Tincture of Hyoscyamus, when assayed by the process given below, should contain in one hundred cubic centimeters 0.007 Gm. of mydriatic alkaloids." *U. S.*

Assay. *U. S.* (8th Rev.).—"Transfer 100 Cc. of Tincture of Hyoscyamus to an evaporating dish, and evaporate it on a water-bath until it measures about 10 Cc. Add, if necessary, sufficient alcohol to dissolve any separated substance, and then assay the resulting liquid by the method given under *Fluidextractum Belladonnæ Radicis* (page 528), using the same details as there directed for 10 Cc. of Fluidextract of Belladonna Root, with the exception that the multiplication by 10 be omitted; the result will represent the weight in grammes of alkaloids contained in one hundred cubic centimeters of Tincture of Hyoscyamus." *U. S.*

"Hyoscyamus Leaves and flowering tops, in No. 20 powder, 2 ounces (Imperial) or 100 grammes; Alcohol (45 per cent.), a sufficient quantity. Moisten the powder with two fluid ounces (Imp. meas.) or one hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure one pint (Imp. meas.) or one thousand cubic centimetres." *Br.*

The strength of the British tincture (1898) was slightly reduced (20 per cent.) in order to bring it into the class of tinctures having the maximum dose of a fluidrachm. The strength was also reduced in the *U. S. P.* (8th Rev.) from 15 per cent. to 10 per cent. and an assay process appended.

This tincture possesses the activities of hyoscyamus. When it purges, as it sometimes does, it may be united with a very small propor-

tion of tincture of opium. The expressed juice preserved by means of alcohol may be employed for the same purposes as the tincture.¹

Dose, one-half to one fluidrachm (1.8 to 3.75 Cc.).

TINCTURA IODI. U. S., Br.

TINCTURE OF IODINE

(tīnc-tū'ra i-ō'dī)

Tinctura Iodini, *Pharm.* 1870; Teinture (alcoolé) d'Iode, *Fr. Cod.*; Tinctura Iodi, *P. G.*; Jodtinktur, *G.*; Solucion alcoholica de yodo, *Sp.*

* "Iodine, *seventy grammes* [or 2 ounces av., 205 grains]; Potassium Iodide, *fifty grammes* [or 1 ounce av., 334 grains]; Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Triturate the Iodine and Potassium Iodide rapidly, in a mortar, to a coarse powder, and transfer it at once to a graduated bottle. Rinse the mortar with several successive portions of Alcohol, and pour the rinsings into the bottle. Then add Alcohol, shaking occasionally, until the Iodine and Potassium Iodide are dissolved, and the finished Tincture measures *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

"Iodine, ½ ounce (Imperial) or 25 grammes; Potassium Iodide, ½ ounce (Imp.) or 25 grammes; Distilled Water, ½ fl. ounce (Imp. meas.) or 25 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity*. Place the Iodine and Potassium Iodide in a bottle with the Distilled Water; when solution has been effected, add a sufficient quantity of the Alcohol to produce *one pint* (Imp. meas.) or *one thousand cubic centimetres* of the Tincture. If 10 cubic centimetres of the Tincture be diluted with 20 cubic centimetres of water, it should require, for complete decoloration, 19.6 cubic centimetres of the volumetric solution of sodium thiosulphate." *Br.*

The process of the U. S. P. 1890 was an improvement in manipulation over that of the former Pharmacopœias, where the saving of time is an object. The iodine in the quantity directed in the formula makes nearly a saturated solution, and by coarsely powdering it, as directed, the solution is greatly facilitated; when the operator has no necessity for dissolving the iodine rapidly, it may simply be placed in the bottle with the solvent and allowed to dissolve slowly. The British tincture is much weaker than that of the U. S. P., the latter being 2.8 times as strong as the British. An important change was made in the formula of tincture of iodine in the U. S. P. (8th Rev.) by the addition of about 5 per cent. of potassium iodide; this improvement not only permits the dilution of the tincture with water without

precipitating the iodine, so that the tincture can now be administered internally, but it also particularly increases the stability of the tincture.

When tincture of iodine made as in previous pharmacopœias by solution of iodine (alone) in alcohol was allowed to stand subjected to varying conditions for two months, the loss in iodine was as high as 7 per cent.; on the other hand the loss in iodine with tincture containing 5 per cent. of potassium iodide was not appreciable in the same length of time under similar treatment. The addition of potassium iodide also causes the iodine to dissolve rapidly in the alcohol. The compound solution of iodine made with water is retained, and is most suitable for internal administration. (See *Liquor Iodi Compositus*.) The iodine should be thoroughly dried before being weighed out. The tincture should be kept in well-stoppered bottles, in order to prevent the evaporation of the alcohol.² It should never be dispensed in cork stoppered vials because of the destructive action of the iodine on the cork; rubber or glass stoppers should be used.

Properties.—The tincture has a deep brown color. One grain of iodine is contained in about fifteen minims, or thirty drops. "If 5 Cc. of the Tincture be mixed with about 25 Cc. of water and titrated with tenth-normal sodium thiosulphate V.S., about 27.25 Cc. of tenth-normal sodium thiosulphate V.S. should be required for complete decolorization (corresponding to about 6.86 Gm. of Iodine in 100 Cc.)." *U. S.* It is at present less used internally than it formerly was, in consequence of an impression that it is apt to irritate the stomach. Water decomposes the tincture when it contains no potassium iodide and it is supposed that when this is swallowed the iodine is precipitated upon the mucous membrane. Besides, the tincture undergoes a gradual change when long kept, owing, according to Guibourt, to a reaction between the alcohol and the iodine. A portion of the latter is supposed to take hydrogen from the former, producing hydriodic acid, which dissolves another portion of the iodine to form iodized hydriodic acid, while the place of the hydrogen in the alcohol is supplied by iodine, giving rise to ethyl iodide and similar products. The new products have an agreeable odor and are soluble in water; and consequently the tincture gradually loses by time the property of being precipitated on dilution. A. Göpel found the change to be so slow, when the tincture is kept in the dark and at a low temperature, that in three months a specimen thus treated had lost but one per cent. of iodine. (*Ph. Cb.*, No. 13, 1850.) Commaille, in 1859, con-

¹ According to Donovan, the tincture when made of leaves from plants of only one year's growth is inert. (*P. J.*, 1871, p. 907.)

² *Tinctura Iodini Composita*. *U. S.* 1870. *Compound Tincture of Iodine*.—"Take of Iodine half a troyounce; Iodide of Potassium a troyounce; Alcohol a pint. Dissolve the Iodine and Iodide of Potassium in the Alcohol." The compound tincture of iodine may be given internally for all the purposes which iodine is capable of answering. The dose is from fifteen to thirty drops (0.45 to 0.9 Cc.), to be gradually increased if necessary.

firmed the labors of the last-mentioned investigator. Subsequent experiments have, however, given results somewhat at variance with those of Guibourt. Carles found that after exposure in a transparent glass flask to diffuse daylight for ten months, the tincture contained only one-twelfth per cent. of hydriodic acid. He was also unable to find any of the ethyl iodide which, according to Guibourt, is formed simultaneously with the acid. (*P. J.*, 3d ser., v. 88.)

Uses.—Tincture of iodine is now employed externally almost exclusively. Locally used, if undiluted, it acts as a powerful irritant to the skin, producing inflammation, desquamation of the cuticle, etc. Nevertheless, it is much used in this state in *erysipelas*, *chilblains*, and other cases of *cutaneous and subcutaneous inflammation*, and with happy effects. But its application requires some caution, and in *erysipelas* it is better to surround the inflamed surface with a border of the tincture, embracing a portion of both the sound and the diseased skin, so as to prevent the progress of the inflammation, than to attempt a complete cure by covering the whole surface affected. The largest use of tincture of iodine is as a rubefacient in *sprains* and chronic joint affections.

It is useful in rendering the *variolous eruption* abortive. It is most conveniently applied by means of a camel's-hair pencil. Diluted with camphorated tincture of soap, or other alcoholic liquid, it is sometimes employed as an embrocation in *scrofulous tumors* and other affections requiring the use of iodine. It is much used in the radical cure of *hydrocele*, as an injection into the sac, and a similar employment of it has been extended to other serous cavities morbidly distended with fluid, as in *ovarian dropsy*, *ascites*, and *empyema*, but in these latter affections it should be resorted to, if at all, with great caution. In *hydrocele*, Velpeau employed it diluted with double its volume of water. In the other cases referred to, it has been variously diluted with from three to ten times its bulk of water or some demulcent liquid. The *Tinctura Iodii Decolorata* of the German Pharmacopœia 1872 is made by digesting at a gentle heat ten parts, each, of iodine, sodium thiosulphate, and distilled water until solution is effected, adding sixteen parts of spirit of ammonia, shaking for a few moments, then adding seventy-five parts of alcohol, allowing the mixture to stand for three days in a cool place, and filtering. This preparation and all similar ones having this name,¹

are calculated to mislead practitioners, for they contain no free iodine, but are variable mixtures, consisting principally of ammonium iodide; the former German tincture contains in addition some ethyl iodide, triethyl-ammonium iodide, and traces of sodium iodide and sulphate. Luc has found the inhalation of the fumes from slightly warmed tinctures very useful in *coryza*.

Lugol's solution is a much preferable preparation for the internal administration of iodine. Debaugue, an apothecary of Mons, has ascertained that tannic acid has the property of rendering iodine soluble in water, and states that an ounce of syrup of orange-peel in four or six ounces of water will form a clear solution with a quantity of tincture of iodine containing five or six grains of the medicine. (*J. P. C.*, 3e sér., xx. 34.) Owing to the caustic effect of the iodine, and the coagulating action of the alcohol, where it is desired to get an absorption of iodine, as in the case of *enlarged glands*, a solution in glycerin or olive oil is preferable to the tincture. (See *Iodum*, page 663.)

Dose, three to five minims (0.2 to 0.3 Cc.).

TINCTURA IPECACUANHÆ ET OPII.

U. S.

TINCTURE OF IPECAC AND OPIUM

[Fluid Dover's Powder]

(tinc-tū'ra ip-ē-căc-ū-ăn'hæ êt ô'pī-i)

* "Tincture of Deodorized Opium, one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]; Fluidextract of Ipecac, one hun-

and a trace of Iodoform. It is recommended for external use whenever a discutient is required, and has been used for its revulsive effects in inflammatory diseases, as *pneumonia* and *rheumatism*. It is recommended also topically in *erysipelas*, *furuncles*, *sprains*, *bruises*, and *neuralgic affections*. (*Am. J. M. S.*, Oct. 1865, 398.) It is stated that on the addition of ammonia some nitrogen iodide is generally precipitated; and, as this is an explosive compound, caution is necessary. The deposit, however, disappears upon the completion of the decolorization. (*A. J. P.*, July, 1869.) Chas. O. Curtman gives the following formula (*A. J. P.*, xli. 364): Take of iodine one ounce and a quarter; Alcohol thirteen fluidounces; Strong Water of Ammonia three fluidounces. Dissolve the Iodine in the Alcohol, and add the Ammonia. Allow to stand for four weeks, with occasional agitation, so that the precipitate may dissolve. A rapid preparation may be made by using an excess of ammonia, and afterwards adding, cautiously, hydrochloric acid until the reaction is only feebly alkaline. Jos. L. Macmillan finds that 5.3 decigrammes of a solution of sodium hydroxide of sp. gr. 1.07 at 15.55° C. will decolorize 3.6 grammes of the British tincture. (*A. J. P.*, xliii. 360.)

Tincture of Iodides (*Ph. Rev.*, 1899, 306) was proposed by Slesker as follows: Dissolve 48.9 Gm. sodium iodide and 47.3 Gm. ammonium iodide in 155.0 Cc. of water, add 10 Cc. of ammonia water (10 per cent.), and then sufficient alcohol to make 1000 Cc. He afterwards suggested that distilled water be used, and that the alcohol be of assured purity. Ordinary alcohol generally contains matter which causes it to assume a yellowish color. This foreign matter, being derived from barrels, it may be removed by re-distillation; but a simpler method for this purpose is to shake 1000 Cc. of the alcohol with 0.5 to 1.0 Gm., or a sufficient quantity of potassium permanganate in coarse powder, until the alcohol acquires a dark purple color; then strain from the excess of permanganate, allow the alcohol to stand for a few hours, and filter. The filtrate should be perfectly colorless, and will produce a colorless tincture of iodides which keeps well in glass-stoppered bottles.

¹ *Tinctura Iodii Decolorata*. *Colorless Tincture of Iodine*.—Under this name a preparation is described by N. J. Aiken of St. Louis, Mo., which is made by mixing equal measures of Compound Tincture of Iodine and Strong Water of Ammonia. The mixture in time becomes colorless, and, if not so at the end of 24 hours, more ammonia may be added, even to the extent of one-fourth if necessary. When wanted weak, it may be diluted to any desired extent by water or glycerin. In consequence of the chemical changes which take place, it is no longer tincture of iodine, but a hydro-alcoholic solution of potassium and ammonium iodides, with more or less ammonia

dred cubic centimeters [or 3 fluidounces, 183 minims]; Diluted Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Evaporate the Tincture of Deodorized Opium, in a tared dish on a water-bath, until it weighs *eight hundred grammes* [or 28 ounces av., 96 grains]. When it has become cold, add to it the Fluidextract of Ipecac, filter the mixture, and pass enough Diluted Alcohol through the filter to obtain *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture." U. S.

This tincture is intended to represent Dover's powder in a liquid form. Ten minims (0.6 Cc.), the adult dose, represent one grain of powdered opium and one grain of ipecac, equivalent to ten grains of Dover's powder.

Dose, five to ten minims (0.3 to 0.6 Cc.).

TINCTURA JABORANDI. Br.

TINCTURE OF JABORANDI

(tinc-tū'rā jāb-q-rān'di)

Tinctura Pilocarpi; Tincture of Pilocarpus; Tincture (alcoolé) de Jaborandi, *Fr. Cod.*; Jaboranditinktur, *G.*; Tintura alcoholica de jaborandi, *Sp.*

"Jaborandi Leaves, in No. 40 powder, 4 ounces (Imperial) or 200 grammes; Alcohol (45 per cent.), *a sufficient quantity*. Moisten the powder with *two and a half fluid ounces* (Imp. meas.) or one hundred and twenty-five cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This preparation possesses no advantages over the fluidextract, but is undoubtedly efficient. The Br. Pharm. gives the dose as from one-half to one fluidrachm; but, as one drachm represents only eleven grains of the jaborandi, it is evidently too small.

Dose, from two to three fluidrachms (7.5 to 11.25 Cc.).

TINCTURA JALAPÆ. Br.

TINCTURE OF JALAP

(tinc-tū'rā jā-lā'pæ)

Telnture (alcoolé) de Jalap, *Fr. Cod.*; Jalapentinktur, *G.*

"Jalap, in No. 40 powder, 4 ounces (Imperial) or 200 grammes; Alcohol (70 per cent.), *a sufficient quantity*. Moisten the powder with *two fluid ounces* (Imp. meas.) or one hundred cubic centimetres of the Alcohol; pack in a percolator; gradually add more of the Alcohol until *twelve fluid ounces* (Imp. meas.) or six hundred cubic centimetres of percolate has been collected; subject the marc to pressure; add the expressed liquid to the percolate; set aside for twenty-four hours; filter. Determine the amount of Jalap Resin present in ten cubic centimetres of the resulting strong tincture by the process described under 'Jalapæ Resina' [p.

1051], and dilute the remainder of the strong tincture with a sufficient quantity of the Alcohol to produce a Tincture containing 1.5 grammes of the Resin in one hundred cubic centimetres. Treated as described under 'Jalapæ Resina,' 10 cubic centimetres of the Tincture should yield not less than 0.145 nor more than 0.155 gramme of the Resin." *Br.*

This tincture is no longer official in the U. S. Pharmacopœia. The tincture of jalap of the U. S. P. 1870 was made by percolating six troy-ounces of powdered jalap with a mixture of two measures of alcohol and one of water, until two pints of tincture were obtained.

This tincture was increased in strength 60 per cent. at the last revision of the Br. Ph. 1898. It possesses the medicinal virtues of jalap, and is sometimes added to cathartic mixtures.

Dose, one-half to one fluidrachm (1.8 to 3.75 Cc.).

TINCTURA KINO. U. S., Br.

TINCTURE OF KINO

(tinc-tū'rā kī-nō)

Telnture (alcoolé) de Kino, *Fr. Cod.*; Kinentinktur, *G.*

* "Kino, *fifty grammes* [or 1 ounce av., 334 grains]; Purified Talc, *ten grammes* [or 154 grains]; Glycerin, *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims]; Alcohol, *six hundred and fifty cubic centimeters* [or 21 fluidounces, 470 minims]; Water, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, and triturate the Kino and Purified Talc with sufficient of the mixture to produce a thin, smooth magma. Transfer this magma to a flask by the aid of the remainder of the mixture, and, having ascertained the weight of the flask and contents, heat it on a water-bath for about one hour; allow the flask and contents to cool, and restore the original weight by the addition of sufficient Water. Then add the Alcohol, mix, and pass the Tincture through a filter of purified cotton, keeping the funnel well covered. Finally, add sufficient Alcohol through the filter to obtain *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture." U. S.

"Kino, in powder, 2 ounces (Imperial) or 100 grammes; Glycerin, 3 fl. ounces (Imp. meas.) or 150 cubic centimetres; Distilled Water, 5 fl. ounces (Imp. meas.) or 250 cubic centimetres; Alcohol (90 per cent.), *a sufficient quantity*. Mix the Glycerin and the Distilled Water; rub the Kino in a mortar with a sufficient quantity of the mixture to form a smooth paste, gradually adding the remainder of the mixture; transfer to a closed vessel; add *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Alcohol; set aside for twelve hours, frequently agitating; filter through a

plug of cotton wool; pass sufficient of the Alcohol through the filter to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture." *Br.*

Much inconvenience is caused by the tendency of this tincture to gelatinize and gradually lose its astringency. The present official formula is believed to furnish a tincture free from objection. It is probable that different specimens of kino vary in their tendency to gelatinize. Groves states that fresh kino will not gelatinize, and Martindale that the Australian kino is much more prone to do so than the East India drug. The air has some effect, for if this be entirely excluded the tincture will keep for a long time without undergoing the change. It should be introduced, when prepared, into very small bottles, which should be kept well corked and be opened only when wanted for use. J. D. Wood obtains a handsome preparation, which he believes to keep well and not gelatinize, by using a menstruum of 2 parts of alcohol sp. gr. 0.835, and 1 part each of water and glycerin.

L. Meyers Connor gets rid of the gelatinizing property by using magnesium carbonate in making the tincture, but it is very probable that a large part of the kino-tannic acid is removed at the same time. (*A. J. P.*, xlv. 260.) P. F. Smith of Louisville, furnished the following formula: "Take of Kino *one ounce and a half*; Ground Logwood *half an ounce*; Diluted Alcohol *a sufficient quantity*. Moisten the Logwood with a portion of the Diluted Alcohol, and introduce it into a displacement apparatus. Dissolve the Kino by triturating with successive portions of Diluted Alcohol, and percolate the solution through the Logwood until a pint of tincture is obtained." We have used this process and have not noticed gelatinization to take place in any instance. Sugar added in equal proportions with the kino employed has been recommended as a preventive of gelatinization, and R. Rother claims permanence for the following formula. Powder one and a half troyounces of kino and half a troy-ounce of catechu, mix them, add ten fluidounces of water, heat for ten or fifteen minutes with constant stirring, and let the mixture cool. Add water to make the mixture twelve fluidounces, and then add four fluidounces of alcohol. Pour the mixture into a bottle containing sixty grains of filter-paper, shake the whole well at intervals, and strain the tincture after twenty-four hours. (*A. J. P.*, 1886, 333.)

The important change in the process of the U. S. Pharmacopœia (8th Revision) is the employment of heat. This was due to the researches of Edmund White (*P. J.*, 1903, May, 644, and Nov. 702), who with David Hooper believes that the gelatinization of tincture of kino is due to an enzyme or oxydase present in the kino; the activity of this is destroyed by heat. Another improvement in the U. S. P. (8th Rev.) is filtration through purified cotton (instead of paper), and the use

of purified talc. Tincture of kino is used chiefly as an addition to chalk mixtures in *diarrhœa*.

Dose, one to two fluidrachms (3.75 to 7.5 Cc.).

TINGTURA KRAMERIAE. U. S., Br.

TINGTURE OF KRAMERIA

(tinc-tû'ra kṛa-mě'ri-æ)

Tincture of Rhatany; Teinture (alcoolé) de Ratanhia, *Fr. Cod.*; Tinctura Ratanhiæ, *P. G.*; Ratanhiatinktur, *G.*

* "Krameria, in No. 40 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Diluted Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the Krameria with *eighty cubic centimeters* [or 2 fluidounces, 338 minims] of Diluted Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Diluted Alcohol to obtain *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

"Krameria Root, in No. 40 powder, 4 ounces (Imperial) or 200 grammes; Alcohol (60 per cent.), *a sufficient quantity*. Moisten the powder with *two fluid ounces* (Imp. meas.) or one hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This tincture was increased in strength 60 per cent. at the last revision of the British Pharmacopœia (1898); it is stated that the tincture made from Pará rhatany furnishes a clear solution on the addition of water, while that from Peruvian root yields a turbid mixture.

The same precaution should be observed in keeping this tincture as is recommended for tincture of kino. It is a good preparation in cases which admit of the use of small quantities of alcohol.

Dose, one or two fluidrachms (3.75 or 7.5 Cc.).

TINGTURA LACTUCARII. U. S.

TINGTURE OF LACTUCARIUM

(tinc-tû'ra læ-tû-că'ri-i)

Teinture (alcoolé) de Lactucarium, *Fr.*; Lactucariumtinktur, *G.*

* "Lactucarium, *five hundred grammes* [or 17 ounces av., 279 grains]; Glycerin, *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims]; Alcohol, Purified Petroleum Benzin, Diluted Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic*

centimeters [or 33 fluidounces, 6½ fluidrachms]. Beat the Lactucarium in an iron mortar, with clean sand, to a coarse powder, and introduce it into a bottle; add *two thousand cubic centimeters* [or 67 fluidounces, 301 minims] of Purified Petroleum Benzin, cork the bottle tightly, set it aside for forty-eight hours, frequently agitating the mixture. Pour the mixture on a double filter, and allow it to drain. Wash the residue by gradually adding *fifteen hundred cubic centimeters* [or 50 fluidounces, 345 minims] of Purified Petroleum Benzin, and allow the Lactucarium to dry by exposing it to a current of air. When it is dry and free from the odor of Benzin, reduce it to powder, using more sand, if necessary, and pack it moderately in a conical percolator. Mix the Glycerin with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, and *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Alcohol, and moisten the powder with *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of the mixture. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed very slowly, gradually adding, first the remainder of the menstruum, and then Diluted Alcohol, until the Lactucarium is exhausted. Reserve the first *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of the percolate, evaporate the remainder on a water-bath, at a temperature not exceeding 70° C. (158° F.), to *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims], and mix this with the reserved portion. Filter, and add enough Diluted Alcohol through the filter to obtain *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture." U. S.

This tincture was first official in the U. S. 1890. It is based on the formula of J. L. Lemberger, who recommended the extraction of the resinous inert lactucarin by treatment with petroleum benzin. Great care must be observed to use *purified* petroleum benzin, as it is almost impossible to get rid of the odor and taste of petroleum in the finished preparation if the ordinary benzin be used. (See *Syrupus Lactucarii*, page 1229.)

Dose, half to one fluidrachm (1.8 to 3.75 Cc.).

Off. Prep.—*Syrupus Lactucarii*, U. S.

two cubic centimeters [or 32 minims]; Saigon Cinnamon, *twenty grammes* [or 309 grains]; Cloves, *five grammes* [or 77 grains]; Myristica, *ten grammes* [or 154 grains]; Red Saunders, *ten grammes* [or 154 grains]; Alcohol, Water, each, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Reduce the Saigon Cinnamon, Cloves, Myristica and Red Saunders to a No. 50 powder, and macerate this powder for three days in a mixture of *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol and *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, in which liquid the Oils have been dissolved. Then filter, and, when the liquid has drained off completely, pass enough of a mixture of Alcohol and Water, made in the same proportions as before, through the residue on the filter to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture." U. S.

"Oil of Lavender, 45 *minims* or 4.7 cubic centimetres; Oil of Rosemary, 5 *minims* or 0.5 cubic centimetre; Cinnamon Bark, bruised, 75 *grains* or 8.5 grammes; Nutmeg, bruised, 75 *grains* or 8.5 grammes; Red Sanders Wood, 150 *grains* or 17 grammes; Alcohol (90 per cent.), 1 *pint* (Imperial measure) or 1000 cubic centimetres. Prepare by the maceration process, adding the Oils at the completion of the process." Br.

The compound tincture of lavender of the U. S. Pharmacopœia is nearly twice the strength of the British preparation, although it is made with a menstruum weaker in alcohol. When properly prepared it is an excellent preparation to be used for *gastric uneasiness, nausea, and flatulence*.

Dose, from thirty minims to a fluidrachm (1.8 to 3.75 Cc.).

Off. Prep.—*Liquor Potassii Arsenitis*, U. S. (Br.).

TINGTURA LIMONIS CORTICIS.

U. S. (Br.)

TINGTURE OF LEMON PEEL

(tinc-tū'ra lī-mō'nīs cōr'tī-cjs)

Tinctura Limonis, Br.; Tincture of Lemon; Tincture (alcoolé) de Zeste de Citron, Fr.; Citronenschalentinktur, G.

* "Lemon Peel, from the fresh fruit, in thin shavings and cut into narrow shreds, *five hundred grammes* [or 17 ounces av., 279 grains]; Alcohol, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Macerate the Lemon Peel in a stoppered, wide-mouthed container, in a moderately warm place, with *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Alcohol during forty-eight hours, with frequent agitation; then filter through purified cotton, and, when the liquid has drained off

TINGTURA LAVANDULÆ COMPOSITA.

U. S., Br.

COMPOUND TINCTURE OF LAVENDER

[Compound Spirit of Lavender]

(tinc-tū'ra lā-vān'dū-læ cōm-pōs'it-ā)

Spiritus Lavandulæ Compositus, U. S. 1870; *Lavender Drops*; *Téinture* (alcoolé) de Lavande composée, Fr.; *Zusammengesetzte Lavendeltinktur*, G.

* "Oil of Lavender Flowers, *eight cubic centimeters* [or 130 minims]; Oil of Rosemary,

completely, gradually pour on enough Alcohol to make *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms] of Tincture, and filter." *U. S.*

"Fresh Lemon Peel, cut small, 5 ounces (Imperial) or 250 grammes; Alcohol (90 per cent.), 1 pint (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

Tincture of lemon peel is a new official preparation of the U. S. P. (8th Rev.). Spirit of lemon made from oil of lemon was abandoned, because the poor quality of the oil with which it was likely to be made caused it to have a terebinthinate flavor. The 50 per cent. tincture made by macerating fresh lemon peel in alcohol was proposed by Scoville and the present formula produces a very satisfactory preparation.

This tincture was doubled in strength at the 1898 revision of the Br. Pharm., but is now only about one-half the strength of the U. S. tincture. It is made with strong alcohol instead of proof spirit formerly used. It forms a grateful aromatic addition to tonic infusions, etc.

Dose, from one to two fluidrachms (3.75 to 7.5 Cc.).

Off. Prep.—Syrupus Acidi Citrici, *U. S.*; Syrupus Hypophosphitum, *U. S.*

TINCTURA LOBELIAE. U. S.

TINCTURE OF LOBELIA

(tinc-tū'ra lō-bē'li-æ)

Teinture (alcoolé) de Lobélie enfiée, *Fr. Cod.*; Tinctura Lobeliae, *P. G.*; Lobellintinktur, *G.*; Tintura di lobelia, *It.*; Tintura alcoolica de lobelia, *Sp.*

* "Lobelia, in No. 50 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Diluted Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Moisten the Lobelia with *forty cubic centimeters* [or 1 fluidounce, 169 minims] of Diluted Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Diluted Alcohol to obtain *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms] of Tincture." *U. S.*

The strength of this tincture was decreased one-half at the last revision. For method of assay, see *C. D.*, 1893, 454; also *P. J.*, 1895, 141. It possesses the emetic and narcotic properties of lobelia, and is much used in *asthma*. The emetic dose is two fluidrachms (7.5 Cc.), but it frequently acts dangerously. A saturated tincture is strongly recommended by A. Livezey

as a local application in *erysipelas*, and in the *eczematous eruption* of *Rhus poisoning*. (*B. M. S. J.*, lv. 262.)

Dose, as an expectorant, fifteen minims to one fluidrachm (0.9 to 3.75 Cc.); as an emetic, one to two fluidrachms (3.75 to 7.5 Cc.).

TINCTURA LOBELIAE ÆTHEREA. Br.

ETHEREAL TINCTURE OF LOBELIA

(tinc-tū'ra lō-bē'li-æ æ-thē're-æ)

Teinture étherée de Lobélie enfiée, *Fr.*; Ætherische Lobellintinktur, *G.*

"Lobelia, in No. 40 powder, 4 ounces (Imperial) or 200 grammes; Spirit of Ether, *a sufficient quantity*. Moisten the powder with *two fluid ounces* (Imp. meas.) or one hundred cubic centimetres of Spirit of Ether, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres. This preparation is made with rather more than one and a half times the proportion of Lobelia ordered for the corresponding preparation in the British Pharmacopœia of 1885." *Br.*

Dose, from five to fifteen minims (0.3 to 0.9 Cc.).

TINCTURA LUPULI. Br.

TINCTURE OF HOPS

(tinc-tū'ra lū'pū-li)

Teinture (alcoolé) de Houblon, *Fr.*; Hopfentinktur, *G.*

"Hops, 4 ounces (Imperial) or 200 grammes; Alcohol (60 per cent.), 1 pint (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

This tincture might well have been omitted in the 1890 revision of the U. S. Pharmacopœia; it has little to recommend it from either a therapeutical or a pharmaceutical point of view. The strength of the British tincture (1898) has been increased 60 per cent. The menstruum is also slightly stronger in alcohol.

Care should be observed to notice that the British tincture of hops is termed "Tinctura Lupuli," a name very similar to the tincture made from lupulin official in the U. S. P. 1870.¹

¹ *Tinctura Lupulinae. Tincture of Lupulin. Teinture de Lupulin, Fr.; Lupulintinktur, G.*—"Take of Lupulin four *troycounces*; Alcohol *a sufficient quantity*. Pack the Lupulin in a cylindrical percolator, and gradually pour Alcohol upon it until two pints of tincture are obtained." *U. S.* 1870.

This is much superior to the tincture of hops of the first U. S. Pharmacopœia, in the place of which it was introduced into the second edition. In the original preparation, a certain quantity of hops was directed, from which the lupulin was to be separated by beating, and then digested in alcohol. As hops contain a variable proportion of lupulin, the tincture thus made must be of unequal strength,—an objection to which the tincture of hops, even as now prepared, is in some measure liable. Besides, the amount of lupulin contained in any quantity of hops upon which alcohol can conveniently act is too small in proportion to the alcohol to afford a tincture of the

The U. S. P. 1890 tincture of hops was made as follows: "Hops, well dried and in No. 20 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Diluted Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Diluted Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Diluted Alcohol upon it, until *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of Tincture are obtained." U. S. 1890.

By thoroughly drying the hops and rubbing them between the hands, or by cutting and bruising them, they may be brought to a state of division which will in a great measure obviate the disadvantages due to their light and bulky character. Yet it is well known that the narcotic virtues of hops are injured by a thorough drying. As the virtues of hops depend chiefly on the lupulin, and as the quantity of this substance is different in different parcels, the tincture is necessarily unequal in strength, and the tincture of lupulin itself is preferable. According to Mérière, tincture of hops deposits, on standing, a yellow precipitate, and a large quantity of a white crystalline substance, which he thinks may be calcium malate.

Tincture of hops is tonic and narcotic, but little reliance can be placed upon it. It is sometimes useful in the wakefulness, attended with tremors and general nervous derangement, to which habitual drunkards are liable, and which frequently precedes an attack of *delirium tremens*.

Dose, from one to three fluidrachms (3.75 to 11.25 Cc.).

TINCTURA MOSCHI. U. S.

TINCTURE OF MUSK

(tinc-tŭ'ra mōs'phī)

Teinture (alcoolé) de Musc. *Fr. Cod.*; Moschustinktur, *G.*; Tintura di muschio, *It.*; Tintura alcoholica de alimziele, *Sp.*

* "Musk, *five grammes* [or 77 grains]; Alcohol, *forty-five cubic centimeters* [or 1 fluidounce, 250 minims]; Water, *forty-five cubic centimeters* [or 1 fluidounce, 250 minims]; Diluted Alcohol, *a sufficient quantity*, to make *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]. Triturate the Musk with the Water, a little at a time, until a smooth mixture is obtained; transfer this mixture to a bottle and allow it to stand for twenty-four hours; add the Alcohol and macerate the mix-

ture for six days, occasionally shaking it. Then filter through a plain paper filter, and, when the liquid has drained off completely, pass enough Diluted Alcohol through the filter to make *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Tincture." U. S.

due strength. The tincture of lupulin is, therefore, greatly preferable. The dose is one or two fluidrachms (3.7 or 7.5 Cc.), to be given in sweetened water or some mucilaginous fluid. Under the name of *Ammoniated Tincture of Lupulin*, Dye Duckworth proposes as the best preparation a tincture made by macerating for seven days two ounces of lupulin in a pint of aromatic spirit of ammonia, and then filtering. The dose is from half a fluidrachm to a fluidrachm (1.9 to 3.7 Cc.). (*A. J. P.*, xii. 416.)

This tincture was reduced in strength about one-half in the U. S. P. 1890, on account of the greatly increased cost of musk. This change, in our opinion, is ill-advised, and does not secure the main object, as the patient will have to take double the dose, even if the alcohol be therapeutically contraindicated. The process has been arranged so as to make the end-product 100 Cc., as very few pharmacists will require 1000 Cc. of tincture of musk. Musk will yield its virtues to the above menstruum if the process be followed; if wanted for its odor it will be economy to add a minim of solution of potassium hydroxide to the water used to rub the musk into a smooth paste. Care should be especially taken to use pure grain musk in this preparation.

Dose, from thirty minims to two fluidrachms (1.8 to 7.5 Cc.).

TINCTURA MYRRHÆ. U. S., Br.

TINCTURE OF MYRRH

(tinc-tŭ'ra mŷr'r'hæ)

Teinture (alcoolé) de Myrrhe, *Fr. Cod.*; Tinctura Myrrhæ, *P. G.*; Myrrhentinktur, *G.*; Tintura di mirra, *It.*; Tintura alcoholica de mirra, *Sp.*

* "Myrrh, in moderately coarse powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Macerate the Myrrh in a stoppered container, in a moderately warm place, with *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol during three days, with frequent agitation; then filter through purified cotton, or a plain paper filter, and, when the liquid has drained off completely, pour on enough menstruum to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture." U. S.

"Myrrh, in coarse powder, 4 ounces (Imperial) or 200 grammes; Alcohol (90 per cent.), *a sufficient quantity*. Place the Myrrh with *sixteen fluid ounces* (Imp. meas.) or eight hundred cubic centimetres of the Alcohol in a closed vessel; set aside for seven days, with frequent agitation; filter; when the liquid ceases to drop, pass sufficient of the Alcohol through the filter to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture." Br.

The strength of this tincture was increased 60 per cent. at the last revision of the British Pharmacopœia (1898).

Official alcohol is preferable to diluted alcohol as a solvent of myrrh, because it forms a perfectly clear tincture, which is not attainable

with the latter menstruum. The addition of water to the tincture renders it turbid. According to E. B. Shuttleworth (*A. J. P.*, xliii. 369), the gum which is left behind in making the tincture may be utilized for making mucilage. The tincture of myrrh is used solely as a local application to stimulate *indolent and foul ulcers, spongy gums, aphthous sore mouth, and ulcerations of the throat.*

Dose, from fifteen to thirty minims (0.9 to 1.8 Cc.).

TINCTURA NUCIS VOMICÆ. U. S., Br.

TINCTURE OF NUX VOMICA

(tinc-tū'ra nū'cis vōm'ic-æ)

Teinture (alcoolé) de Noix vomique, *Fr. Cod.*; Tinctura Strychni, *P. G.*; Brechnusstinktur, Krähenaugentinktur, *G.*; Tintura di noce vomica, *It.*; Tinctura alcoholica de nuez vomica, *Sp.*

* "Extract of Nux Vomica (containing 5 percent. of strychnine), *twenty grammes* [or 309 grains]; Alcohol, Water, each, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the Extract of Nux Vomica in a sufficient quantity of a mixture of Alcohol and Water, made in the proportion of *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol and *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, to make the solution measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms], and filter through a well-covered filter. Tincture of Nux Vomica, when assayed by the process given below, should contain in *one hundred cubic centimeters* 0.1 Gm. of Strychnine." *U. S.*

"Liquid Extract of Nux Vomica, 2 *fl. ounces* (Imperial measure) or 100 cubic centimetres; Distilled Water, 3 *fl. ounces* (Imp. meas.) or 150 cubic centimetres; Alcohol (90 per cent.), a *sufficient quantity*. Mix the Liquid Extract of Nux Vomica with the Distilled Water; add sufficient of the Alcohol to produce *twelve fluid ounces* (Imp. meas.) or six hundred cubic centimetres of the Tincture; filter. Treated by the assay process given under 'Extractum Nucis Vomicae Liquidum,' 100 cubic centimetres should yield not less than 0.24 nor more than 0.26 gramme of Strychnine, corresponding to about ½ grain in 1 fluid drachm or ¼ grain in 110 minims. This preparation contains about twice the proportion of Strychnine present in the Tincture of Nux Vomica of the British Pharmacopœia of 1885." *Br.*

Assay. *U. S.* (8th Rev.)—"Transfer 100 Cc. of Tincture of Nux Vomica to a porcelain dish, evaporate it to dryness on a water-bath, and assay the resulting extract by the method given under *Extractum Nucis Vomicae* (page 482), using the same details as there directed for 2 Gm. of Extract of Nux Vomica, with the exception that the multiplication by 50 be omitted; the result will represent the weight

in grammes of strychnine contained in *one hundred cubic centimeters* of Tincture of Nux Vomica." *U. S.*

The object of the *U. S.* (8th Rev.) process is to secure a more reliable and definite tincture than was possible under the process official prior to 1890; for this reason 2 per cent. of the standardized extract is directed to be dissolved in a mixture of 3 volumes of alcohol and 1 volume of water. On account of the very tough structure of nux vomica, percolation is accomplished usually with varying results. The amount of extract present in the percolate is to some extent a measure of its activity; hence, if a weighed portion of the percolate be evaporated to dryness, and the percentage of dry extract is noted, it is easy to calculate the amount present in the whole quantity. The strength of tincture of nux vomica *U. S. P.* (8th Rev.) is theoretically about one-fourth weaker than the tincture of the *U. S. P.* 1890. It is probable, however, that as the assay process is now based on the tincture containing 0.1 Gm. of strychnine instead of 0.3 Gm. total alkaloids in 100 Cc., that the difference in strength will be practically less than this.

The British Pharmacopœia standardizes the liquid extract (see p. 551), and makes its tincture from it of such strength that 100 Cc. shall contain 0.25 Gm. of strychnine; the menstruum used is slightly more alcoholic than that of the *Br. Ph.* 1885, and the tincture is two and a half times as strong as the *U. S.* (8th Rev.) tincture. R. Rother (*A. J. P.*, Jan. 1883) after experimenting with various substances, found that sodium chloride aided greatly in softening the bassorin-like substance in which the alkaloidal principles of nux vomica are embedded, and he proposes its use by adding it to the menstruum of diluted alcohol in the proportion of 120 grains to the pint (see *U. S. D.*, 16th ed., p. 1527). The alcoholic extract, or strychnine, is preferable to the tincture, when the pill form is practicable.

Dose, of the tincture, ten to twenty minims (0.6 to 1.3 Cc.), to be increased if necessary.

TINCTURA OPII. U. S., Br.

TINCTURE OF OPIUM LAUDANUM

(tinc-tū'ra ō'pī-i)

Tinctura Thebæica, Tinctura Meconii, Tinctura Extracti Opii; Teinture d'Extrait d'Opium, *Fr. Cod.*; Teinture (alcoolé) d'Opium, Teinture thébæique, *Fr.*; Tinctura Opii Simplex, *P. G.*; Einfache Opiumtinktur, *G.*; Tintura di oppio, *It.*; Tintura alcoholica de opio, *Sp.*

* "Granulated Opium (containing 12 to 12.5 percent. of crystallizable morphine), *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, Water, Diluted Alcohol, each, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Heat *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of water to boiling, and pour it on the Granulated Opium contained

in a tared vessel, weigh, and stir occasionally during twelve hours; then restore the original weight by the addition of cold Water, add *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Alcohol, pour the mixture into a bottle, and continue the maceration for forty-eight hours, occasionally shaking. Transfer the mixture to a percolator, return the first portion of the percolate until it runs through clear, and, when the liquid ceases to drop, continue the percolation slowly, pouring on sufficient Diluted Alcohol until *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] are obtained." U. S.

The official requirements are that "Tincture of Opium, when assayed by the process given below, should contain in *one hundred cubic centimeters* not less than 1.2 nor more than 1.25 Gm. of crystallizable morphine." U. S.

Assay.—U. S. (8th Rev.). "Tincture of Opium, *one hundred cubic centimeters*; Ammonia Water, *three and one-half cubic centimeters*; Alcohol, Ether, Water, Lime Water, each, *a sufficient quantity*. Transfer 100 Cc. of Tincture of Opium to an evaporating dish and evaporate it on a water-bath to about 20 Cc., add 40 Cc. of water, mix thoroughly, and set the liquid aside for one hour, occasionally stirring to disintegrate the resinous flakes adhering to the dish. Then filter the liquid and wash the filter and residue with water, until all soluble matter is extracted (indicated by an almost colorless filtrate), and collect the washings separately. First evaporate the washings, in a tared dish, to a small volume, then add the first filtrate and evaporate the whole to a weight of 14 Gm. Determine the morphine in this extract by the method given under Opium (page 903, eighteenth line from the top, beginning with the word "Rotate"), using the same details as there directed for 10 Gm. of Opium, with the exception that the final multiplication by 10 be omitted. The result will represent the weight in grammes of crystallized morphine yielded by *one hundred cubic centimeters* of Tincture of Opium." U. S.

"Opium, 3 ounces (Imperial) or 150 grammes; Alcohol (90 per cent.), Distilled Water, of each *a sufficient quantity*. Rub the Opium to a paste with *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of Distilled Water, previously heated to at least 200° F. (93.3° C.); set aside for six hours; add *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Alcohol; mix thoroughly; set aside in a covered vessel for twenty-four hours; strain; press; mix the liquids; set aside for twenty-four hours; filter.

Determine the proportion of morphine in the resulting strong tincture by the following process: Pour 80 cubic centimetres of the liquid into a porcelain dish; evaporate on a water-bath until the volume is reduced to 30 cubic centimetres; mix the residual liquid in a mortar with 3 grammes of freshly slaked lime; dilute the mixture with water to 85 cubic centimetres;

set aside for half an hour, stirring occasionally. Filter off 50 cubic centimetres of the liquid (representing 50 cubic centimetres of the strong tincture) through a plaited filter, having a diameter of about one decimetre, into a wide-mouthed stoppered bottle, having a capacity of two hundred cubic centimetres; add 5 cubic centimetres of alcohol (90 per cent.) and 30 cubic centimetres of ether; shake the mixture; add 2 grammes of ammonium chloride; shake well and frequently during half an hour; set aside for 12 hours for the morphine to separate. Counterbalance two small filters; place one within the other in a small funnel in such a way that the triple fold of the inner filter shall be superposed upon the single fold of the outer filter; wet them with ether; remove the ethereal layer of the liquid in the bottle as completely as possible by means of a small pipette, and transfer it to the filter; pour into the bottle 15 cubic centimetres of ether; rotate the contents and set the bottle aside; transfer the separated ethereal layer carefully, by means of the pipette, to the filter; wash the filter with a total amount of 10 cubic centimetres of ether added slowly, and in portions; let the filter dry in the air; pour upon it the liquid in the bottle, in portions, in such a way as to transfer the granular crystalline morphine as completely as possible to the filter. When all the liquid has passed through, wash the remainder of the morphine from the bottle with *morphinated water*, until the whole has been removed. Wash the crystals with *morphinated water* until the washings are free from color; allow the filter to drain; dry it, first by gentle pressure between sheets of bibulous paper, afterwards at a temperature between 131° and 140° F. (55° and 60° C.), finally at 230° F. (110° C.) for 2 hours. Weigh the crystals in the inner filter, counterbalancing by the outer filter. Take 0.3 gramme of the crystals, and titrate with *decinormal volumetric solution of sulphuric acid*, as directed under Opium.

Add to the weight of anhydrous morphine, indicated by the titration, 0.05 gramme (or 0.1 gramme for every 100 cubic centimetres of the original filtrate, should more than 50 cubic centimetres have been used for the estimation), a proportion representing the average loss of morphine during the process.

Having ascertained the proportion of morphine, calculated as anhydrous, present in the 50 cubic centimetres of strong tincture, the remainder is to be diluted with sufficient of a mixture of Alcohol (90 per cent.) and Distilled Water, in equal volumes, to produce a Tincture of Opium containing 0.75 gramme of morphine, calculated as anhydrous, in 100 cubic centimetres. Treated by the foregoing process, Tincture of Opium should yield an amount of morphine, reckoned as anhydrous, corresponding to not less than 0.70 gramme, nor more than 0.80 gramme, in 100 cubic centimetres. This preparation contains, on an average, the soluble matter of 32.8 grains of Opium (con-

taining 10 per cent. of morphine, calculated as anhydrous) in 1 fluid ounce, or about 1 grain of such Opium in 15 minims. Tincture of Opium may be prepared with any variety of opium containing a known percentage of morphine, calculated as anhydrous, provided that the percentage be not less than seven and a half, and provided that the resulting Tincture of Opium respond to the foregoing quantitative test." *Br.*

The proportion of opium in these formulas is not quite the same, the U. S. P. tincture containing about twelve grains more of opium in the fluidounce than the British. The *Br. Pharm.* 1898 does not direct opium *in powder*, but relies upon an assay to bring the product to a uniform strength. The drying and granulating of the opium are clearly useful provisions, as they insure greater uniformity in the strength of the tincture. Crude opium contains variable proportions of water, and laudanum prepared from a moist specimen will be weaker than that prepared from an equal weight of the dried. The granulation insures the previous drying of the drug, and is thus useful independently of the greater facility which it gives to the action of the menstruum; it is, however, often neglected. Deviation from the official strength in so important a preparation is certainly a great evil. There can be little doubt, we think, that the present U. S. formula insures a more complete exhaustion of the opium than did the former simple procedure of maceration for six days, while the saving in time is apparent. Granulated opium is preferred to powdered opium because of the greater facility of extraction. Opium in fine powder cannot be readily percolated with diluted alcohol, but if it be mixed with an equal weight of an insoluble powder like purified talc there will be no difficulty; percolation will necessarily be slow, but this is just what is required to secure thorough exhaustion.¹

In the United States and Great Britain this tincture is universally known by the name of *laudanum*. As this term was formerly applied to other preparations of opium, and still continues to be so applied on the continent of Europe, the tincture is sometimes distinguished by the epithet *liquidum*, which, however, is seldom used in this country. *Tinctura Thebaica* is another title by which the preparation is known.

About two-thirds of the opium used in the preparation of the tincture are dissolved, the residue consisting chiefly of inert matter. Allowing the opium to be wholly exhausted of its active principles, one grain would be represented by very nearly 10.5 minims, according to the U. S. formula (8th Rev.); but a small quantity of morphine has been detected in the

residuary matter, so that the tincture is rather weaker than the proportion of opium employed would indicate. This difference, however, is too slight to be of any practical importance. In general practice, laudanum very rarely fully comes up to the official standard, and a large proportion of that in the market is far below it. This is especially the case with the cheap laudanums which are so extensively sold to country stores.

The tincture of opium is used for all the purposes to which opium itself is applied. (See *Opium*.) The dose, equivalent to a grain of opium, is about eleven minims (0.65 Cc.), or twenty-two drops. It should be recollected that a fluidrachm or teaspoonful of laudanum (60 minims) will yield, on an average, about 120 drops. Laudanum, when long kept, with occasional exposure to the air, becomes thick from the evaporation of a portion of the alcohol and the deposition of solid matter. If given in this state, it often acts with unexpected energy, and death has resulted in infants from doses which would have been entirely safe if the tincture had been clear. *Denarcotized laudanum* may be prepared by substituting the denarcotized opium for the opium itself.

Dose, five to ten minims (0.3 to 0.6 Cc.).

Off. Prep.—Linimentum Opii, *Br.*; Tinctura Camphoræ Composita, *Br.*; Tinctura Opii Ammoniata, *Br.*

TINCTURA OPII AMMONIATA. *Br.*

AMMONIATED TINCTURE OF OPIUM

(tinc-tū'ra ō'pī-i am-mo-nī-ā'tā)

Scotch Paregoric; Tincture d'Opium ammoniacale, *Fr.*; Ammoniakalische Opiumtinktur, *G.*

"Tincture of Opium, 3 *fl. ounces* (Imperial measure) or 150 cubic centimetres; Benzoic Acid, 180 *grains* or 20.6 grammes; Oil of Anise, 1 *fl. drachm* (Imp. meas.) or 625 cubic centimetres; Solution of Ammonia, 4 *fl. ounces* (Imp. meas.) or 200 cubic centimetres; Alcohol (90 per cent.), a *sufficient quantity*. Dissolve the Oil of Anise and the Benzoic Acid in *twelve fluid ounces* (Imp. meas.) or six hundred cubic centimetres of the Alcohol; add the Tincture of Opium and the Solution of Ammonia; mix well; filter; add enough of the Alcohol to form *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture. This preparation contains the soluble matter of nearly 0.62 grain of Opium (containing 10 per cent. of morphine, reckoned as anhydrous) in 1 fluid drachm, or of nearly 5 grains of such Opium in 1 fluid ounce." *Br.*

This is an old preparation of the Edinburgh Pharmacopœia, formerly used in Scotland under the name of Paregoric Elixir. It differs, however, both in composition and in strength, from the very popular preparation known as Paregoric in the United States. As ammonia precipitates morphine from its solu-

¹ *Tinctura Opii Murtatica*.—Under this name is sometimes prescribed a preparation made by the following formula: Powdered Opium *one ounce*; Muriatic Acid *one fluidounce*; Distilled Water *fifteen fluidounces*. Macerate for 14 days, filter, and add sufficient water to make a pint.

tions, it was doubted whether the tincture contained any of that alkaloid, but if the ammonia be in sufficient excess it will redissolve the morphine. At best, however, the preparation is of doubtful propriety, for if the ammoniacal addition should not happen to have the requisite strength, or if the ammonia should escape or become carbonated by exposure, the strength of the tincture might be affected. Influenced, we presume, by considerations of this kind, the editors of the first British Pharmacopœia rejected the preparation altogether. But popular preference, although local, led to its readmission into the Br. Pharmacopœia, though in a slightly modified form, strong solution of ammonia and rectified spirit being substituted for the Edinburgh spirit of ammonia, which is not official in the Br. Pharmacopœia.

Dose, from thirty minims to a fluidrachm (1.8 to 3.75 Ce.).

TINCTURA OPII CAMPHORATA.

U. S. (Br.)

CAMPHORATED TINCTURE OF OPIUM PAREGORIC

(tinc-tū'ra ō'pī-i cām-phō-rā'ta)

Tinctura Camphoræ Composita, Br.; Compound Tincture of Camphor; Elixir parégorique, Fr. Cod.; Teinture (alcoolé) d'Opium Camphrée, Fr.; Tinctura Extracti Opii Camphorata, Elixir Paregoricum, Tinctura Opii benzoica, P. G.; Benzoësaurehaltige Opiumtinktur, G.

* "Powdered Opium, four grammes [or 62 grains]; Benzoic Acid, four grammes [or 62 grains]; Camphor, four grammes [or 62 grains]; Oil of Anise, four cubic centimeters [or 65 minims]; Glycerin, forty cubic centimeters [or 1 fluidounce, 169 minims]; Diluted Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Place all the ingredients in a stoppered container and macerate for three days with frequent agitation; then filter the mixture through a well-covered paper filter, adding sufficient Diluted Alcohol through the filter to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Tincture." U. S.

"Tincture of Opium, 585 minims or 60.9 cubic centimetres; Benzoic Acid, 40 grains or 4.6 grammes; Camphor, 30 grains or 3.4 grammes; Oil of Anise, 30 minims or 3.1 cubic centimetres; Alcohol (60 per cent.), a sufficient quantity. Dissolve the Benzoic Acid, Camphor, and Oil of Anise in eighteen fluid ounces (Imperial measure) or nine hundred cubic centimetres of the Alcohol; add the Tincture of Opium and a sufficient quantity of the Alcohol to produce one pint (Imp. meas.) or one thousand cubic centimetres of the Tincture; filter if necessary. This Compound Tincture of Camphor contains in each fluid drachm a proportion of Tincture of Opium equivalent to 1-30th grain of Morphine Hydrochloride, or to ¼ grain of Opium (containing 10 per cent.

of anhydrous morphine); or to nearly 0.5 milligramme (0.00046 gramme) of anhydrous morphine in each cubic centimetre." Br.

This is the well-known *paregoric*. It is a very pleasant anodyne, much used to allay cough, to relieve nausea and slight pains in the stomach and bowels, to check diarrhœa, and, in infantile cases, to procure sleep. Half a fluidounce of the U. S. or British tincture contains rather less than a grain of powdered opium. The substitution of glycerin for the honey of the U. S. P. 1870 is an improvement which aids in retaining the transparency of the filtered tincture. Licorice was omitted in 1840, in consequence of giving the dark color of laudanum and thus leading to mistake.

Dose, for an infant, from five to twenty minims (0.3 to 1.3 Ce.); for an adult, from one to four fluidrachms (3.75 to 15 Ce.).¹

TINCTURA OPII DEODORATI. U. S.

TINCTURE OF DEODORIZED OPIUM

(tinc-tū'ra ō'pī-i dē-ō-dō-rā'ti)

Deodorized tincture of opium, U. S. 1880; Teinture (alcoolé) d'Opium sans odeur, Fr.; Desodorirte Opiumtinktur, G.

* "Granulated Opium (containing 12 to 12.5 percent. of crystallizable morphine), one hundred grammes [or 3 ounces av., 231 grains]; Purified Petroleum Benzin, seventy-five cubic centimeters [or 2 fluidounces, 257 minims]; Alcohol, two hundred cubic centimeters [or 6 fluidounces, 366 minims]; Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Heat five hundred cubic centimeters [or 16 fluidounces, 435 minims] of Water to boiling, and pour it on the Granulated Opium contained

¹ The following formulas were adopted by the Philadelphia College of Pharmacy in 1833 for the preparation of the old compound tinctures of opium so much used under the names of *Bateman's drops* and *Godfrey's cordial*. So long as these nostrums are employed, it is important that they should be prepared in a uniform manner and of a certain strength, as serious consequences may happen from diversity in the formulas when so active a substance as opium is the chief ingredient. Such diversity has existed to a very great extent; so much so that in one formula for Bateman's drops the quantity of opium was seven and a half grains to the pint, while in another it exceeded one hundred grains. It was in order to remedy this evil that the College was induced to adopt the formulas here presented.

"*Bateman's Pectoral Drops*.—Take of Diluted Alcohol 4 gallons, Red Saunders, rasped, 2 oz. tr. Digest for twenty-four hours, filter, and add of Opium in powder, 2 oz. tr. Catechu, in powder, 2 oz. tr., Camphor, 2 oz. tr. Oil of Anise 240 m. Digest for ten days." This preparation is about equal in strength to the camphorated tincture of opium or paregoric elixir of the U. S. Pharmacopœia, containing about two grains of opium to the fluidounce.

"*Godfrey's Cordial*.—Take of Tincture of Opium 24 fld. oz., Molasses (from the sugar refiners) 16 pints, Alcohol 2 pints, Water 26 pints, Potassium Carbonate 20 oz. av., Oil of Sassafras 4 fld. dr. Dissolve the Potassium Carbonate in the Water, add the Molasses, and heat over a gentle fire till they simmer; take off the scum which rises, and add the Laudanum, Alcohol, and Oil of Sassafras, having previously mixed them well together. This preparation contains the strength of rather more than one grain of opium in a fluidounce." (A. J. P., v. 26 and 27.) Death has been produced by it in the infant. (P. J., 3d ser., i. 199.)

in a suitable vessel, stirring the mixture frequently during twenty-four hours. Then transfer the mixture to a percolator, return the first portion of the percolate until it runs through clear, and, when the liquid ceases to drop, continue the percolation with Water until the Opium is exhausted. Concentrate the percolate by evaporation on a water-bath until it measures *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims], and, when cooled, shake it frequently and vigorously for ten minutes with *sixty-five cubic centimeters* [or 2 fluidounces, 95 minims] of the Purified Petroleum Benzin. Separate the Benzin, repeat the shaking out for a few minutes with the remainder of the Benzin, and, having carefully and completely separated this second portion of Benzin, evaporate the remaining liquid in a warm place spontaneously, until the odor of Benzin has disappeared, removing the last traces by the heat of a water-bath. Mix the deodorized liquid so obtained with *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Water, filter the mixture through a paper filter, and, having mixed the Alcohol with the filtrate, wash the filter with sufficient Water to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture." U. S.

Assay. U. S. (8th Rev.).—"If 100 Cc. of Tincture of Deodorized Opium be assayed by the process given under *Tinctura Opii* (page 1279), it should yield not less than 1.2 nor more than 1.25 Gm. of crystallized morphine." U. S.

This is an excellent preparation of opium, calculated to supersede various extra-official *elixirs* or *solutions*, which have had more or less use, based upon the real advantages they afforded, in offering liquid preparations of opium exempt from certain noxious ingredients in the crude drug and in the official tinctures which rendered them so offensive to some constitutions, and in some conditions of disease, as almost to forbid their use. A liquid extract is first made from granulated opium in which are left behind all the ingredients of opium insoluble in water; and this, being well shaken with purified benzin, is further deprived of all the principles soluble in this fluid, including narcotine and the noxious odorous matter which is probably one of the most offensive and least useful constituents of opium. The purified benzin is then entirely separated, and, the residue having been dissolved in water, the solution is filtered, and mixed with enough alcohol to preserve it. It had been repeatedly recommended by several pharmacists to replace the ether used in the U. S. P. 1890 process with petroleum benzin, which removes the narcotine just as well as does the ether, and has the merit of being much cheaper. The objection, however, was that benzin almost invariably leaves a trace of a taste and an odor like those of petroleum, and hence it is not fitted for use in a remedy used almost exclusively internally, but the employment of purified petroleum benzin

in the U. S. P. (8th Rev.) should obviate this objection. Patch found that acetone, which had been suggested as a substitute for ether, was open to the same objection as petroleum benzin. The following simplified process was proposed by E. C. Federer as a substitute for the official one. Macerate the dried and powdered drug in twice its weight of water at about 138° F. (a mixture of 1 part of water at about 50° to 75° F. with 1 part at about 210° F.), overnight, or about 12 hours, in a moderately warm place not above from 80° to 90° F., in a partially closed flask. Pour the mass into a wetted double precipitate filter: when the liquid ceases to pass, rinse out the flask with 1 part more of the water at about 138° F., and pass this through the mass. Repeat this once, and, if necessary, again repeat, so as to obtain from 4 to 5 parts of moderately concentrated liquor; the residue will under these circumstances become exhausted. Cool the percolate to as near 32° F. as possible, and filter, placing a piece of ice in the filter to keep the temperature down. If necessary, repass the first portion until the liquid comes through clear; when the last portion has passed, wash the filter with sufficient ice-water to obtain a filtrate of 8 parts; lastly, add alcohol 2 parts. Federer states that a permanent, bright, clear tincture results, practically free from narcotine and thoroughly deodorized. (*D. C.*, 1887, 77.)

Frederick T. Gordon (*A. J. P.*, 1900, 576.) recommends an improved process for preparing tincture of deodorized opium in which he proposes paraffin in place of ether for deodorizing the aqueous extract of opium. The opium, in a granulated condition, is extracted with water practically as directed by the Pharmacopœia. The first 300 Cc. of percolate from 100 Gm. of drug are received, the subsequent portions are evaporated to 200 Cc., and the two portions, being mixed, are heated to 180° F. Then 150 Gm. of paraffin U. S. P. are added, and when this has melted the mixture is shaken thoroughly for five or ten minutes and set aside to cool. When the paraffin has hardened, the crust is broken and the aqueous opium solution poured out, the under side of the paraffin crusts being washed with a little water and the washings added to the decanted liquid, which is brought to 800 Cc. To this, 200 Cc. of alcohol are added and finally enough water to make 1000 Cc. of finished product. The paraffin removes the narcotine and odorous matter, but none of the morphine (the latter existing in the opium, as is well known, as meconate, and this is insoluble in the melted paraffin.) A. E. Ebert (*A. J. P.*, 1902, 157) prefers gasolin to benzin and objects to the use of paraffin, or paraffin oils because of their liability to dissolve some of the morphine; he recommends a *concentrated liquid opium* to be used in making the various galenical opium preparations.

Dose, five to ten minims (0.3 to 0.6 Cc.).

Off. Prep.—*Tinctura Ipecacuanhæ et Opii*, U. S.

TINCTURA PHYSOSTIGMATIS. U. S.**TINCTURE OF PHYSOSTIGMA**

(tinc-tŭ'ra phŭ-sŏ-stig'mă-tîs)

Teinture (alcoolé) de fève du Calabar, *Fr.*; Kalabar-bohnentinktur, *G.*

* "Physostigma, in No. 50 powder (containing 0.15 percent. of ether-soluble alkaloids), *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the Physostigma, with *forty cubic centimeters* [or 1 fluidounce, 169 minims] of Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Alcohol to obtain *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture. Tincture of Physostigma, when assayed by the process given below, should contain in *one hundred cubic centimeters* 0.014 Gm. of the ether-soluble alkaloids from Physostigma." *U. S.*

Assay. *U. S.* (8th Rev.)—"Transfer 100 Cc. of Tincture of Physostigma to a porcelain dish, evaporate it to dryness on a water-bath, and assay the resulting extract by the method given under *Extractum Physostigmatis* (page 486), using the same details as there directed for 1 Gm. of Extract of Physostigma, with the exception that the product must be multiplied by 2 instead of 200; the result will represent the weight in grammes of ether-soluble alkaloids from Physostigma contained in *one hundred cubic centimeters* of Tincture of Physostigma." *U. S.*

This tincture was reduced from a 15 per cent. strength (*U. S. P.* 1890) to a 10 per cent. tincture in the *U. S. P.* (8th Rev.) and an assay process appended. This tincture of Calabar Bean is much weaker than that proposed by Fraser, which was nearly as strong as a fluidextract,—five minims representing three grains of the drug.

Dose, of the official tincture, from twenty to forty minims (1.3 to 2.5 Cc.).

TINCTURA PODOPHYLLI. Br.**TINCTURE OF PODOPHYLLUM**

(tinc-tŭ'ra pŏd-o-phŭll'i)

Teinture (alcoolé) de Résine de Podophyllum, *Fr.*; Podophyllintinktur, *G.*

"Podophyllum Resin, 320 grains or 36.5 grammes; Alcohol (90 per cent.), *a sufficient quantity*. Add the Podophyllum Resin to *eighteen fluid ounces* (Imperial measure) or nine hundred cubic centimetres of the Alcohol,

and set aside for twenty-four hours, occasionally agitating; filter; pass sufficient of the Alcohol through the filter to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture. This Tincture contains twice the proportion of Podophyllum Resin ordered for the corresponding preparation in the British Pharmacopœia of 1885." *Br.*

The introduction of this tincture is of doubtful utility.

Dose, five to fifteen minims (0.3 to 0.9 Cc.).

TINCTURA PRUNI VIRGINIANÆ. Br.**TINCTURE OF VIRGINIAN PRUNE**

(tinc-tŭ'ra prŭ'nĭ vĭr-jĭn-l'ă-næ)

Teinture (alcoolé) d'Ecorce de Cerisier, *Fr.*; Wild-kirschenrindentinktur, *G.*

"Virginian Prune Bark, in No. 20 powder, 4 ounces (Imperial) or 200 grammes; Alcohol (90 per cent.), 12½ fl. ounces (Imp. meas.) or 625 cubic centimetres; Distilled Water, 7½ fl. ounces (Imp. meas.) or 375 cubic centimetres. Mix the powder with the Distilled Water; set aside in a closed vessel for twenty-four hours; add the Alcohol, and complete the maceration process." *Br.*

This is a new official tincture of the *Br. Pharm.* 1898; its utility is doubtful, and its new English name is more than unfortunate. The use of a little glycerin to retard precipitation would be advisable.

Dose, from one-half to one fluidrachm (1.8 to 3.75 Cc.).

TINCTURA PYRETHRI. U. S., Br.**TINCTURE OF PYRETHRUM**

(tinc-tŭ'ra pŭ-rĕ'thrĭ)

Tincture of Pellitory; Teinture (alcoolé) de Pyréthre (racine), *Fr. Cod.*; Bertramwurzelinktur, *G.*

* "Pyrethrum, in No. 50 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the Pyrethrum with *eighty cubic centimeters* [or 2 fluidounces, 338 minims] of Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Alcohol to obtain *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

"Pyrethrum Root, in No. 40 powder, 4 ounces (Imperial) or 200 grammes; Alcohol (70 per cent.), *a sufficient quantity*. Moisten the powder with *three fluid ounces* (Imp. meas.)

or one hundred and fifty cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This tincture is a powerful local irritant, and is an ingredient in several well-known mouth and tooth washes. For its uses, which are purely external, see *Pyrethrum*.

TINCTURA QUASSIÆ. U. S., Br.

TINCTURE OF QUASSIA

(tinc-tŭ'ra quas'si-æ)

Teinture (alcoolé) de Quassie Amère, *Fr.*; Quassia-tinktur, *G.*

* "Quassia, in No. 50 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Alcohol, Water, each, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of Alcohol with *six hundred and fifty cubic centimeters* [or 21 fluidounces, 470 minims] of Water. Moisten the Quassia with *sixty cubic centimeters* [or 2 fluidounces, 14 minims] of this menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

"Quassia Wood, rasped, 2 ounces (Imperial) or 100 grammes; Alcohol (45 per cent.), 1 pint (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

The strength of this tincture was doubled in the U. S. P. (8th Rev.) and is twice that of the present British tincture. It may be employed as an addition to tonic infusions or mixtures.

Dose, one-half to one fluidrachm (1.8 to 3.75 Cc.).

TINCTURA QUILLAJÆ. U. S. (Br.)

TINCTURE OF QUILLAJA

(tinc-tŭ'ra quil-lă-jæ)

Tinctura Quillaiz, *Br.*; Teinture (alcoolé) d'Écorce de Quillaja, *Fr.*; Seifenrindentinktur, *G.*

* "Quillaja, in No. 20 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Alcohol, *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims]; Water, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Boil the Quillaja in a covered vessel with *eight*

hundred cubic centimeters [or 27 fluidounces, 24 minims] of Water for fifteen minutes, strain while hot, and wash the residue on the strainer with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, previously heated to boiling. Then evaporate the strained liquid to *six hundred cubic centimeters* [or 20 fluidounces, 138 minims], allow it to cool, add the Alcohol, and set it aside for twelve hours. Decant the clear liquid, filter it through paper, then pour the residue on the filter, and, when the liquid ceases to drop, wash the filter with sufficient Water to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

"Quillaia Bark, in No. 20 powder, 1 ounce (Imperial) or 50 grammes; Alcohol (60 per cent.), a *sufficient quantity*. Moisten the powder with *half a fluid ounce* (Imp. meas.) or twenty-five cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This tincture, which was made official in the U. S. P. 1890 for the first time, is almost exclusively used as an emulsifying agent. Its medicinal activity, however, limits its use. (See *Quillaja*, p. 1035.) The British tincture is only one-fourth the strength of the U. S. preparation.

Dose, from one-half to one fluidrachm (1.8 to 3.75 Cc.).

TINCTURA QUININÆ. Br.

TINCTURE OF QUININE

(tinc-tŭ'ra quj-nī'næ)

Teinture (alcoolé) de Quinine, *Fr.*; Chinintinktur, *G.*

"Quinine Hydrochloride, 175 grains or 20 grammes; Tincture of Orange, 1 pint (Imperial measure) or 1000 cubic centimetres. Dissolve the Quinine Hydrochloride in the Tincture of Orange." *Br.*

Quinine sulphate was replaced in this preparation by the hydrochloride in the 1885 Br. Pharmacopœia, because, as pointed out by Wright (*Y. B. P.*, 1884, 537), the sulphate was not always soluble in the proportion of tincture of orange peel ordered.

Dose, a fluidrachm (3.75 Cc.) (about equal to one and one-tenth grains of quinine hydrochloride).

TINCTURA QUININÆ AMMONIATA.

Br.

AMMONIATED TINCTURE OF QUININE

(tinc-tŭ'ra quj-nī'næ am-mō-nī-ā'ta)

Teinture Ammoniacale de Quinine, *Fr.*; Ammoniakhaltige Chinintinktur, *G.*

"Quinine Sulphate, 175 grains or 20 grammes; Solution of Ammonia, 2 fl. ounces (Impe-

rial measure) or 100 cubic centimetres; Alcohol (60 per cent.), 18 *fl. ounces* (Imp. meas.) or 900 cubic centimetres. Mix the Solution of Ammonia with the Alcohol; add the Quinine Sulphate; shake until a clear solution is produced; set aside for three days; filter." *Br.*

Dose, one fluidrachm (3.75 Ce.), representing about one and one-tenth grains of quinine sulphate.

TINCTURA RHEI. U. S. (Br.)

TINCTURE OF RHUBARB

(tinc-tŭ'ra rhē'ī)

Tinctura Rhei Composita, *Br.*; Compound Tincture of Rhubarb; Teinture (alcoolé) de Rhubarbe, *Fr. Cod.*; Rhubarbertinktur, *G.*; Tintura di rabarbaro, *It.*

* "Rhubarb, two hundred grammes [or 7 ounces av., 24 grains]; Cardamom, forty grammes [or 1 ounce av., 180 grains]; Glycerin, one hundred cubic centimeters [or 3 fluidounces, 183 minims]; Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with five hundred cubic centimeters [or 16 fluidounces, 435 minims] of Alcohol, and four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Water. Reduce the Rhubarb and Cardamom to a No. 40 powder, and moisten this powder with ninety cubic centimeters [or 3 fluidounces, 21 minims] of this menstruum; transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for twelve hours; then pack it moderately and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on first the remainder of the menstruum, and then sufficient of a mixture of Alcohol and Water, made in the same proportions as before, to obtain one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

"Rhubarb Root, in No. 20 powder, 2 ounces (Imperial) or 100 grammes; Cardamom Seeds, bruised, ½ ounce (Imp.) or 12.5 grammes; Coriander Fruit, bruised, ½ ounce (Imp.) or 12.5 grammes; Glycerin, 2 *fl. ounces* (Imp. meas.) or 100 cubic centimetres; Alcohol (60 per cent.), a sufficient quantity. Moisten the solid ingredients with two fluid ounces (Imp. meas.) or one hundred cubic centimetres of the Alcohol; proceed with the percolation process until a volume of eighteen fluid ounces (Imp. meas.) or nine hundred cubic centimetres of liquid has been obtained; agitate; set aside for forty-eight hours; filter; mix with the Glycerin." *Br.*

This tincture was doubled in rhubarb and cardamom strength in the U. S. P. (8th Rev.).

The tincture of rhubarb on standing lets fall a yellow deposit. This has been shown by James T. King (*A. J. P.*, xlii.) to be in most cases largely composed of chrysophanic acid. He proposed to remedy this by the use of a stronger alcohol, or, as recommended by J. B. Moore (*A. J. P.*, xlv. 306), by the substitution of glycerin for a portion of the alcohol. We have not found that either of these plans entirely prevents precipitation, although glycerin is an aid in this direction.¹

Dose, from one to two fluidrachms (3.75 to 7.5 Ce.).

TINCTURA RHEI AROMATICA. U. S.

AROMATIC TINCTURE OF RHUBARB

(tinc-tŭ'ra rhē'ī ār-q-măt'ī-cə)

Teinture (alcoolé) de Rhubarbe aromatique, *Fr.*; Aromatische Rhubarbertinktur, *G.*

* "Rhubarb, two hundred grammes [or 7 ounces av., 24 grains]; Saigon Cinnamon, forty grammes [or 1 ounce av., 180 grains]; Cloves, forty grammes [or 1 ounce av., 180 grains]; Myristica, twenty grammes [or 309 grains]; Glycerin, one hundred cubic centimeters [or 3 fluidounces, 183 minims]; Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with five hundred cubic centimeters [or 16 fluidounces, 435 minims] of Alcohol and four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Water. Reduce the Rhubarb, Saigon Cinnamon, Cloves, and Myristica to a No. 40 powder, and moisten this powder with ninety cubic centimeters [or 3 fluidounces, 21 minims] of this menstruum; transfer it to a percolator, and, without pressing the powder, allow it to stand for twelve hours; then pack it moderately and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close

¹ *Tinctura Rhei Dulcis*, *U. S.* 1890. *Sweet Tincture of Rhubarb*.—"Rhubarb, one hundred grammes [or 3 ounces av., 231 grains]; Glycyrrhiza, forty grammes [or 1 ounce av., 180 grains]; Anise, forty grammes [or 1 ounce av., 180 grains]; Cardamom, ten grammes [or 154 grains]; Glycerin, one hundred cubic centimeters [or 3 fluidounces, 183 minims]; Alcohol, Water, Diluted Alcohol, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix the Rhubarb Glycyrrhiza, Anise, and Cardamom, and reduce the mixture to a moderately coarse (No. 40) powder. Mix the Glycerin with five hundred cubic centimeters [or 16 fluidounces, 435 minims] of Alcohol and four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Water. Moisten the powder with one hundred and fifty cubic centimeters [or 5 fluidounces, 35 minims] of the menstruum, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour on the remainder of the menstruum. When the liquid has disappeared from the surface, gradually pour Diluted Alcohol upon it, until one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Tincture are obtained." *U. S.* 1890.

This is a tincture which has been frequently used in Philadelphia and other sections of our country; it is preferable to the simple tincture for administration to children, on account of its more agreeable taste. The dose is from two to three fluidrachms (7.5 to 11.25 Ce.).

the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on first the remainder of the menstruum, and then sufficient of a mixture of Alcohol and Water, made in the same proportions as before, to obtain *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

This is the tincture which is used in making the aromatic syrup of rhubarb. It is preferable to separate the preparations, as it is occasionally desirable to prescribe the tincture without the admixture with syrup, while the pharmacist will always prefer to make the tincture in quantity and keep it on hand, since it is permanent, and add to it syrup to make the aromatic syrup when needed.

Dose, for an adult, from one-half to one fluidrachm (1.8 to 3.75 Cc.).

Off. Prep.—Syrupus Rhei Aromaticus, *U. S.*

TINCTURA SANGUINARIÆ. U. S.

TINCTURE OF SANGUINARIA

[Tincture of Blood Root]

(tinc-tŭ'ra sân-gu'ñā-rî-æ)

Teinture (alcoolé) de Sanguinaire, *Fr.*; Blutwurzeltinktur, *G.*

* "Sanguinaria, in No. 60 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Acetic Acid, *twenty cubic centimeters* [or 325 minims]; Alcohol, Water, each, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *six hundred cubic centimeters* [or 20 fluidounces, 128 minims] of Alcohol with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Water. Moisten the Sanguinaria with the Acetic Acid and *thirty cubic centimeters* [or 1 fluidounce, 7 minims] of this menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

This tincture was reduced from 15 per cent. (*U. S. P.* 1890) to 10 per cent. in the *U. S. P.* (8th Rev.).

A precipitate will generally be found deposited upon the sides and bottoms of bottles containing this tincture. *W. J. McConn (A. J. P., 1884, p. 505)* recommended the addition of an alkaline citrate, preferably potassium citrate, as a preventive. He found sanguinarine in the precipitate. The official menstruum now contains 2 per cent. of acetic acid, with a view of preventing precipitation. This tincture is

emetic in the *dose* of from three to four fluidrachms (11.25 to 15 Cc.); but it is rather intended to act as an expectorant or an alterative, for which purpose from fifteen to sixty minims (0.9 to 3.75 Cc.) may be given.

TINCTURA SCILLÆ. U. S., Br.

TINCTURE OF SQUILL

(tinc-tŭ'ra scil'la)

Teinture (alcoolé) de Scille, *Fr. Cod.*; Meerzwiebel-tinktur, *G.*; Tinctura alcoholica de scilla, *Sp.*

* "Squill, in No. 20 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, Water, each, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water. Macerate the Squill with *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of the menstruum, in a closed vessel, in a moderately warm place for three days, occasionally stirring, and express strongly. Repeat this operation with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of menstruum, macerating one day before expression; and, finally, macerate the residue for six hours in sufficient menstruum to make the united expressed liquids measure about *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Express as before, mix the expressed liquids, filter through paper, and pass sufficient menstruum through the filter to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

"Squill, bruised, 4 ounces (Imperial) or 200 grammes; Alcohol (60 per cent.), 1 pint (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

Tincture of Squill was reduced from the strength of 15 per cent. (*U. S. P.* 1890) to 10 per cent. *U. S. P.* (8th Rev.). This tincture yields a grayish, rose-colored, very bitter and acrid deposit, consisting of silky tufts. (*Ménière.*) The tincture possesses all the virtues of squill, and may be given whenever the spirituous menstruum is not objectionable.

Dose, as an expectorant or a diuretic, from ten to twenty minims (0.6 to 1.3 Cc.) (from twenty to forty drops).

TINCTURA SENEGÆ. Br.

TINCTURE OF SENEGA

(tinc-tŭ'ra sên'ê-gæ)

Teinture (alcoolé) de Polygala de Virginie, *Fr.*; Senegatinktur, *G.*

"Senega Root, in No. 40 powder, 4 ounces (Imperial) or 200 grammes; Alcohol (60 per cent.), a *sufficient quantity*. Moisten the powder with *four fluid ounces* (Imp. meas.) or two hundred cubic centimetres of the Alcohol, and

complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

The Br. Pharm. 1898 increased the strength of this preparation 60 per cent. The tincture is efficient, but it is hardly needed while recourse can be had to the fluidextract or the syrup.

Dose, from thirty minims to two fluidrachms (1.8 to 7.5 Cc.).

TINCTURA SENNÆ COMPOSITA. Br.

COMPOUND TINCTURE OF SENNA

(tinc-tū'ra sēn'næ cōm-pōs'ī-tā)

Elixir Salutis: Teinture (alcoolé) de Séné composée, Teinture de Séné aromatique, *Elixir de Salut, Fr.*; Zusammengesetzte Sennatinktur, *G.*

"Senna, broken small, 4 ounces (Imperial) or 200 grammes; Raisins of commerce, freed from seeds, 2 ounces (Imp.) or 100 grammes; Caraway Fruit, bruised, $\frac{1}{2}$ ounce (Imp.) or 25 grammes; Coriander Fruit, bruised, $\frac{1}{2}$ ounce (Imp.) or 25 grammes; Alcohol (45 per cent.), 1 pint (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

The Br. Pharm. 1898 increased the proportion of senna in this preparation 60 per cent.

This tincture is the *elixir salutis* of the old Pharmacopœias. It is a warm cordial purgative, useful in *costiveness* attended with flatulence, and in *atonic gout*, especially when occurring in intemperate persons. It is also added to cathartic infusions and mixtures. Tincture of senna yields a yellow deposit, disposed in plates, containing starch and white crystals of calcareous salts. (Ménière.)

Dose, from two to four fluidrachms (7.5 to 15 Cc.).

TINCTURA SERPENTARIÆ. U. S., Br.

TINCTURE OF SERPENTARIA

(tinc-tū'ra sēr-pen-tā'ri-æ)

Tincture of Serpentry: Teinture (alcoolé) de Serpentinaire de Virginie, *Fr.*; Schlangenzwurzeltinktur, *G.*

* "Serpentaria, in No. 50 powder, two hundred grammes [or 7 ounces av., 24 grains]; Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix six hundred and fifty cubic centimeters [or 21 fluidounces, 470 minims] of Alcohol with three hundred and fifty cubic centimeters [or 11 fluidounces, 401 minims] of Water. Moisten the Serpentinaire with sixty cubic centimeters [or 2 fluidounces, 14 minims] of this menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower ori-

fice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

"Serpentary Rhizome, in No. 40 powder, 4 ounces (Imperial) or 200 grammes; Alcohol (70 per cent.), a sufficient quantity. Moisten the powder with four fluid ounces (Imp. meas.) or two hundred cubic centimeters of the Alcohol, and complete the percolation process. The resulting Tincture should measure one pint (Imp. meas.) or one thousand cubic centimeters." *Br.*

Tincture of Serpentinaire was doubled in strength in the U. S. P. (8th Rev.). This tincture is little other than a feebly aromatic, alcoholic stimulant. The Br. Pharm. 1898 increased the strength of this preparation 60 per cent., and it is now of the same strength as the U. S. P. tincture.

Dose, thirty minims to two fluidrachms (1.8 to 7.5 Cc.).

TINCTURA STRAMONII. U. S., Br.

TINCTURE OF STRAMONIUM

(tinc-tū'ra strā-mō'nī-i)

Tincture of Stramonium Leaves: Teinture (alcoolé) de Stramoline (feuille), *Fr. Od.*; Stechapfel-blättertinktur, *G.*

* "Stramonium, in No. 60 powder (containing not less than 0.35 percent. of mydriatic alkaloids), one hundred grammes [or 3 ounces av., 231 grains]; Diluted Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the Stramonium with forty cubic centimeters [or 1 fluidounce, 169 minims] of Diluted Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for three hours; then pack it firmly and pour on enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, gradually pouring on Diluted Alcohol until one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] are obtained. Tincture of Stramonium, when assayed by the process given below, should contain in one hundred cubic centimeters 0.03 Gm. of mydriatic alkaloids from Stramonium." *U. S.*

Assay. *U. S.* (8th Rev.).—"Transfer 100 Cc. of Tincture of Stramonium to an evaporating dish, and evaporate it on a water-bath until it measures about 10 Cc. Add, if necessary, sufficient alcohol to dissolve any separated substance, and then assay the resulting liquid by the method given under *Fluidextractum Belladonna Radicis* (page 528), using the same details as there directed for 10 Cc. of Fluid-

extract of Belladonna Root, with the exception that the multiplication by 10, as there directed, be omitted; the result will represent the weight in grammes of alkaloids contained in *one hundred cubic centimeters* of Tincture of Stramonium." U. S.

"Stramonium Leaves, in No. 20 powder, 4 ounces (Imperial) or 200 grammes; Alcohol (45 per cent.), a sufficient quantity. Moisten the powder with *four fluid ounces* (Imp. meas.) or two hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." Br.

This tincture is now made from Stramonium leaves instead of the seeds as directed by the U. S. P. 1890, and the strength made 10 per cent. instead of 15 per cent., as in the U. S. P. 1890, and an assay has been appended. The Br. Pharm. 1898 increased the strength of this preparation 60 per cent., but changed the form of the drug from seed to leaves. The British tincture is now double the strength of the U. S. P. (8th Rev.) tincture.

Dose, from ten to twenty minims (0.6 to 1.3 Cc.); of the British tincture, five to fifteen minims (0.3 to 0.9 Cc.).

TINCTURA STROPHANTHI. U. S., Br.

TINCTURE OF STROPHANTHUS

(tinc-tū'ra strō-phăn'thī)

Teinture (alcoolé) de Strophanthus Kombé, Fr. Cod.; Tinctura Strophanthi, P. G.; Strophanthusinktur, G.; Strophanthussamentinktur, G.; Tintura di strofanto, It.; Tintura alcoholica de estrofanto, Sp.

"NOTE.—The strength of this tincture has been increased from 5 Gm. of Strophanthus in 100 Cc. to 10 Gm. of Strophanthus in 100 Cc." U. S.

"Strophanthus, in No. 60 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, Water, each, a sufficient quantity, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *six hundred and fifty cubic centimeters* [or 21 fluidounces, 470 minims] of Alcohol with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of Water. Moisten the Strophanthus with *fifty cubic centimeters* [or 1 fluidounce, 331 minims] of this menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture." U. S.

"Strophanthus Seeds, in No. 30 powder, ½ ounce (Imperial) or 25 grammes; Alcohol (70

per cent.), a sufficient quantity. Pack the powder in a percolator; moisten it with *one fluid drachm* (Imp. meas.) or six cubic centimetres of the Alcohol; set aside for forty-eight hours; pour on successive quantities of the Alcohol, allowing percolation to proceed slowly, until a total volume of *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of percolate has been obtained; filter; add a sufficient quantity of the Alcohol to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Tincture. This preparation is made with half the proportion of Strophanthus Seeds ordered for the corresponding preparation in the British Pharmacopœia of 1885 (Additions 1890)." Br.

Tincture of Strophanthus was doubled in strength in the U. S. P. (8th Rev.) (the U. S. P. 1890 tincture being 5 per cent.), and is now about four times the strength of the British tincture. The Br. Pharm. 1885 preparation was based on Fraser's formula, as improved by Wm. Martindale;¹ but the 1898 revision practically adopted the process of the U. S. tincture and dropped the method of previous treatment with ether to remove the fatty oil. Undoubtedly the simplest way of overcoming this difficulty is to add sufficient water to the alcoholic menstruum to prevent the solution of the oil, which is thus thrown out with the residue. Warrington subjects the tincture to a temperature of 32° F., and filters out the fatty deposit. (West. Drug., 1892, 448.) Strophanthus seeds are reduced to powder with great difficulty. E. R. Squibb bruises them (after drying perfectly) in an iron mortar with broken glass. (Ephem., vol. iii. 1252.) Made by either process, the tincture is usually slightly cloudy when first prepared, but on standing soon becomes of a bright amber color. Petroleum benzin has been used in place of ether in Fraser's process for extracting the fixed oil, but it has only the advantage of economy, communicating a petroleum-like taste and odor to the tincture.

Uses.—This is an efficient and popular preparation, which fully represents the crude drug. (See Strophanthus.)

¹ Tincture of Strophanthus (Fraser's process). Strophanthus Seeds, deprived of their comose appendices, reduced to powder, and dried, 1 ounce; Ether, freed from spirit and from water, 10 fluidounces; Rectified Spirit (alcohol), a sufficiency to obtain 1 pint, or 20 fluidounces. Remove entirely the stalks and comose appendices from the seeds, reduce the seeds to a moderately fine powder, dry the powder by exposing for twelve hours to a temperature of 100° or 120° F., and weigh. Pack in a percolator, add ether until the whole of the powder is saturated and a small quantity of the ether has dropped into the receiver; arrest the percolation for twenty-four hours, and then continue percolating slowly until the whole of the ether has been used. If the last ether percolate should not be almost colorless, use more ether. Remove the powder from the percolator, expose to the air, and break up any lumps after the ether has sufficiently evaporated; continue the exposure, heating the powder, if necessary, to 100° or 120° F., until all the ether has evaporated, when a uniform, nearly white, dry powder may be easily obtained. Repack the powder in the percolator, add enough of rectified spirit to moisten it thoroughly, arrest the further flow of the spirit, macerate for forty-eight hours, and pass rectified spirit slowly through until 20 fluidounces of tincture have been obtained.

Dose, from five to ten minims (0.3 to 0.6 Cc.); of the British tincture ten to thirty minims (0.6 to 1.8 Cc.).

TINGTURA SUMBUL. Br.

TINGTURE OF SUMBUL

(tīnc-tū'rā sūm'būl)

Teinture (alcoolé) de Sumbul, *Fr.*; Moschuswurzel-tinktur, Sumbultinktur, *G.*

"Sumbul Root, bruised, 2 ounces (Imperial) or 100 grammes; Alcohol (70 per cent.), 1 pint (Imp. meas.) or 1000 cubic centimetres. Prepare by the maceration process." *Br.*

Tincture of Sumbul was not introduced into the U. S. P. (8th Rev.). The process of the U. S. P. 1890 is appended.¹

This tincture is very little if at all employed in this country; for its properties, see *Sumbul*.

Dose, from twenty minims to a fluidrachm (1.3 to 3.75 Cc.).

TINGTURA TOLUTANA. U. S., Br.

TINGTURE OF TOLU

(tīnc-tū'rā tō-lō-tā'nā)

Tincture of Balsam of Tolu; Teinture (alcoolé) de Baume de Tolu, *Fr. Cod.*; Tolu balsamtinktur, *G.*

* "Balsam of Tolu, two hundred grammes [or 7 ounces av., 24 grains]; Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Macerate the Balsam of Tolu in eight hundred cubic centimeters [or 27 fluidounces, 24 minims] of Alcohol, shaking frequently until dissolved; then filter through paper, and wash the filter with sufficient Alcohol to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

"Balsam of Tolu, 2 ounces (Imperial) or 100 grammes; Alcohol (90 per cent.), a sufficient quantity. Place the Balsam of Tolu in sixteen fluid ounces (Imp. meas.) or eight hundred cubic centimetres of the Alcohol; set aside in a closed vessel; agitate occasionally; when the Balsam is dissolved, filter; pass sufficient of the Alcohol through the filter to produce one pint (Imp. meas.) or one thousand cubic centimetres of the Tincture." *Br.*

This tincture was doubled in strength in the U. S. P. (8th Rev.). The British tincture (1898) was reduced 20 per cent. in the proportion of balsam and is half the strength of the U. S. P. (8th Rev.) tincture.

The tincture of tolu has the properties of the balsam, and may be employed as an addition to expectorant mixtures in chronic bronchitis, but the proportion of alcohol is too large to allow of its advantageous use in some cases. It is used in preparing the syrup of tolu. In smaller quantities it is often employed to flavor cough mixtures. It is decomposed by water.

Dose, one-half to two fluidrachms (1.8 to 7.5 Cc.).

Off. Prep.—Syrupus Tolutanus, *U. S.*

TINGTURA VALERIANÆ. U. S.

TINGTURE OF VALERIAN

(tīnc-tū'rā vā-lē-rī-ā'næ)

Teinture (alcoolé) de Valériane, *Fr. Cod.*; Tinctura Valerianæ, *P. G.*; Baldriantinktur, *G.*; Tintura di valeriana, *It.*

* "Valerian, in No. 60 powder, two hundred grammes [or 7 ounces av., 24 grains]; Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix seven hundred and fifty cubic centimeters [or 25 fluidounces, 173 minims] of Alcohol with two hundred and fifty cubic centimeters [or 8 fluidounces, 218 minims] of Water. Moisten the Valerian with sixty cubic centimeters [or 2 fluidounces, 14 minims] of this menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum to obtain one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

The proportion of alcohol was increased in the U. S. 1890 tincture, to prevent precipitation, and this strength has been retained in the present revision. It is now three parts of alcohol to one part of water. The tincture possesses the properties of valerian, but cannot be given in some cases, so as to produce the full effects of the root, without stimulating too highly, in consequence of the large proportion of spirit. It deposits on standing a black, very cohesive precipitate, with starch, and a yellow extractive matter. (Ménière.)

Dose, one to four fluidrachms (3.75 to 15 Cc.).

TINGTURA VALERIANÆ AMMONIATA. U. S., Br.

AMMONIATED TINCTURE OF VALERIAN

(tīnc-tū'rā vā-lē-rī-ā'næ ām-mō-nī-ā'tā)

Tinctura Valerianæ Composita; Teinture de Valériane ammoniacale, *Fr.*; Ammoniakalische Baldriantinktur, *G.*

¹ "Sumbul, in No. 30 powder, one hundred grammes [or 3 ounces av., 231 grains]; Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix Alcohol and Water in the proportion of six hundred and fifty cubic centimeters [or 21 fluidounces, 470 minims] of Alcohol to three hundred and fifty cubic centimeters [or 11 fluidounces, 401 minims] of Water. Moisten the powder with one hundred cubic centimeters [or 3 fluidounces, 183 minims] of the menstruum, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it until one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Tincture are obtained." *U. S.* 1890.

* "Valerian, in No. 60 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Aromatic Spirit of Ammonia, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Moisten the Valerian with *sixty cubic centimeters* [or 2 fluidounces, 14 minims] of Aromatic Spirit of Ammonia, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough Aromatic Spirit of Ammonia to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Aromatic Spirit of Ammonia to obtain *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms] of Tincture." U. S.

"Valerian Rhizome, in No. 40 powder, 4 ounces (Imperial) or 200 grammes; Oil of Nutmeg, 30 minims or 3.1 cubic centimetres; Oil of Lemon, 20 minims or 2.1 cubic centimetres; Solution of Ammonia, 2 fl. ounces (Imp. meas.) or 100 cubic centimetres; Alcohol (60 per cent.), 18 fl. ounces (Imp. meas.) or 900 cubic centimetres. Mix the liquid ingredients, and prepare by the maceration process." Br.

The proportion of valerian was increased 60 per cent. in the Br. Pharm. 1898, and the aromatic spirit of ammonia replaced by alcohol, solution of ammonia, and volatile oils.

The ammonia in this preparation is thought to assist the solvent powers of the alcohol, while it co-operates with the valerian in medicinal action. The quantity of valerian was very judiciously increased one-third in the U. S. revision of 1880. The tincture is employed as an antispasmodic in *hysteria* and other *nervous diseases*.

Dose, from thirty minims to a fluidrachm (1.8 to 3.75 Cc.), in sweetened water, milk, or some mucilaginous fluid.

TINCTURA VANILLÆ. U. S.

TINCTURE OF VANILLA

(tinc-tû'ra vā-nîl'æ)

Teinture (alcoolé) de Vanille, Fr.; Vanilletinktur, G.

* "Vanilla, cut into small pieces and bruised, *one hundred grammes* [or 3 ounces av., 231 grains]; Sugar, in coarse powder, *two hundred grammes* [or 7 ounces, 24 grains]; Alcohol, Water, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Mix *six hundred and fifty cubic centimeters* [or 21 fluidounces, 470 minims] of Alcohol with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of Water. Macerate the Vanilla in *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of the mixture for twelve hours;

then drain off the liquid and set it aside. Transfer the Vanilla to a mortar, beat it with the Sugar into a uniform powder, then pack it in a percolator and pour upon it the reserved liquid. When this has disappeared from the surface, continue the percolation by gradually pouring on sufficient menstruum to make *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms] of Tincture." U. S.

This tincture will be easily recognized as the so-called *fluidextract of vanilla*. The object of the preliminary maceration of the cut vanilla is to soften it, so that it may be easily disintegrated when beaten up with the sugar; if the details of the above process be carefully carried out and the alcohol be deodorized, a very satisfactory preparation will result. It is used as a flavoring agent, also to make *vanilla syrup*, by adding one ounce of the tincture to sufficient syrup to make one pint. For a paper on flavoring extracts by Scoville, see *Bull. Pharm.*, 1902, 153, 188.

TINCTURA VERATRI. U. S.

TINCTURE OF VERATRUM

[Tinctura Veratri Viridis, Pharm. 1890]

(tinc-tû'ra vē-rā'trî)

Tincture of Green Hellebore; Tincture of American Hellebore; Teinture (alcoolé) de Vêratre, Fr.; Tinctura Veratri, P. G.; Nieswurzeltinktur, G.

"NOTE.—The strength of this tincture has been reduced from 40 Gm. of Veratrum Viride in 100 Cc. to 10 Gm. of Veratrum in 100 Cc." U. S.

* "Veratrum, in No. 60 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Moisten the Veratrum with *forty cubic centimeters* [or 1 fluidounce, 169 minims] of Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Alcohol to obtain *one thousand cubic centimeters* [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms] of Tincture." U. S.

The U. S. tincture of American hellebore of 1890 was of the same strength as Norwood's tincture, which, when prepared by its author, was supposed to be saturated. This may be true of certain ingredients of the root, though probably not in reference to the active principle or principles which it may contain. The strength of this tincture was reduced by the U. S. P. (8th Rev.) from 40 per cent. to 10 per cent. in order to have it conform with the recommendations of the Brussels Congress con-

cerning potent tinctures (see *Tincturæ*). This action will probably result in increasing the use of the fluidextract, which is a better preparation.

Dose, of U. S. tincture, ten to thirty minims (0.6 to 1.8 Cc.).

TINCTURA ZINGIBERIS. U. S., Br.

TINCTURE OF GINGER

(tinc-tū'rā zīŋ-gīb'ē-rīs)

Telnture (alcoolé) de Gingembre, *Fr. Cod.*; Tinctura Zingiberis, *P. G.*; Ingwertinctur, *G.*

* "Ginger, in No. 50 powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Alcohol, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the Ginger with *sixty cubic centimeters* [or 2 fluidounces, 14 minims] of Alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient Alcohol to obtain *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Tincture." *U. S.*

"Ginger, in No. 40 powder, *2 ounces* (Imperial) or 100 grammes; Alcohol (90 per cent.), *a sufficient quantity*. Moisten the powder with *two fluid ounces* (Imp. meas.) or one hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

The strength of this tincture was reduced at the 1880 revision one-third, to bring it into the 20 per cent. class; this is not a disadvantage, however, in view of the introduction of the fluidextract, and the dose is not now inconveniently large.

The tincture of the British Pharmacopœia, though more than twice as strong as was that of the London and Edinburgh Colleges, is still too weak in the proportion of ginger. In consequence of the mucilaginous matter contained in ginger, the tincture made with diluted alcohol or proof spirit is apt to be turbid. Alcohol or rectified spirit is, therefore, properly preferred. Official Jamaica ginger only should be used; for, while a darker-colored preparation is made when the inferior varieties are substituted, the apparent increase in strength is due to coloring matter, and not to the presence of a larger amount of volatile oil or resin.

The tincture of ginger is a useful carminative, and may often be beneficially added to tonic and purgative infusions or mixtures in debilitated states of the alimentary canal. It is in this country largely used for the preparation of a syrup of ginger, for which purpose, however, the fluidextract is official, and

is better even than the strong tincture of the Br. Pharmacopœia 1885, which was dropped at the 1898 revision.

Dose, eight to forty minims (0.5 to 2.5 Cc.).

Off. Prep.—Acidum Sulphuricum Aromaticum, *U. S., Br.*; Liquor Sennæ Concentratus, *Br.*; Pilula Scammonii Composita, *Br.*

TINCTURÆ. U. S.

TINCTURES

(tinc-tū'ræ)

Telntures (Alcooliques) Alcoolés, *Fr.*; Tincturen, *G.*; Tinture alcooliche, *It.*; Tinturas alcoholicas, *Sp.*

Tinctures, in the pharmaceutical sense of the term, are alcoholic solutions of medicinal substances, prepared by maceration, digestion, or percolation. Solutions in spirit of ammonia and ethereal spirit are embraced under the same denomination, but are severally distinguished by the titles of *ammoniated tinctures* and *ethereal tinctures*. The advantages of alcohol as a menstruum are that it dissolves principles which are sparingly or not at all soluble in water, and contributes to their preservation when dissolved, while it leaves behind some inert substances which are dissolved by water. In no instance, however, is absolute alcohol employed. The U. S. Pharmacopœia directs it of the sp. gr. 0.816 at 15.6° C. (60° F.), the British, 0.834. When of these densities it contains water, and is capable of dissolving more or less of substances which are insoluble in anhydrous alcohol, while its solvent power in relation to bodies soluble in that fluid is sufficient for all practical purposes. Diluted alcohol or proof spirit is often preferable to official alcohol, as it is capable of extracting a larger proportion of those active principles of plants which require an aqueous menstruum, while at the same time it is strong enough to prevent spontaneous decomposition, and has the advantages of being cheaper and less stimulating, although a few tinctures when prepared with proof spirit or diluted alcohol undergo some deterioration in time, in consequence of acetous fermentation taking place in the alcoholic fluid. The best preventive is to keep them in full and well-closed bottles, at a low temperature. The diluted alcohol of the different Pharmacopœias is not of the same strength; that of the United States consists of equal volumes of official alcohol and water, and has the sp. gr. of about 0.936 at 15.6° C. (60° F.), while the British has four official diluted alcohols,—70, 60, 45, and 20 per cent. Alcohol or rectified spirit is preferred as a solvent when the substance to be extracted or dissolved is nearly or quite insoluble in water, as in the instances of resins, guaiac, camphor, and the essential oils. The presence of water is here injurious, not only by diluting the menstruum, but also by exercising an affinity for the alcohol which interferes with its solvent power. Thus, water added to an alcoholic solution of one

of these bodies produces a precipitate by abstracting the alcohol from it. Diluted alcohol or proof spirit is employed when the substance is soluble both in alcohol and in water; or when one or more of the ingredients are soluble in the one fluid and one or more in the other, as in the case of vegetable bodies which contain extractive or tannin, or the natural salts of the alkaloids, or gum united with resin or essential oil. As these include the greater number of medicines from which tinctures are prepared, diluted alcohol is most frequently used. In the preparation of the tinctures, the drug should be dry, and properly comminuted by being bruised, sliced, or pulverized. It is usually better in a moderately fine than in a very fine powder; the proper degree depends, however, upon the ease with which the menstruum extracts the soluble principles.

Tinctures were at one time universally prepared by maceration or digestion. Our own Pharmacopœia formerly directed maceration at ordinary temperatures, and extended the period to two weeks. The latter plan was preferable, as it was more convenient and equally effectual, the lower temperature being compensated by the longer maceration. In several instances in which maceration is ordered in the Pharmacopœia, it is still continued for seven days, but the period is very properly altered to suit the character of the substance acted on, and sometimes continued no longer than is necessary for its solution, when it is wholly soluble, as in the tinctures of iodine and tolu. When circumstances require that the tincture should be speedily prepared, digestion may be resorted to. Care should always be taken to keep the vessels well stoppered, in order to prevent the evaporation of the alcohol. The materials should be frequently shaken during the digestion or maceration, and this caution is especially necessary when the substance acted on is in the state of powder. The tincture should not be used until the maceration is completed, when it should be separated from the dregs either by simply filtering it through paper, or, when force is requisite, by expressing it through linen, and filtering.

The plan of preparing tinctures by percolation has been extensively adopted, and has been found to answer well when skilfully executed. In the present edition of our Pharmacopœia, percolation has been adopted as the rule, maceration being directed in some instances in which it was deemed preferable. The British Pharmacopœia, preferring maceration or digestion in several instances, has adopted percolation as a rule, but, as if unprepared to trust this process alone, has combined with it a preliminary maceration of forty-eight hours, and a final expression, so as to separate the last remains of the tincture from the dregs. Perhaps these modifications may be desirable in instances where the operator is not sufficiently skilful, but percolation, properly managed, is of itself adequate to all

the desired purposes, even to the removal of almost the last drop of impregnated menstruum from the dregs, and in our Pharmacopœia it is taken for granted that the apothecary has acquired the requisite skill. Where the operator cannot trust himself in this respect, it would be better to recur to the old method of maceration for safety. The reader will find rules for the proper management of the process of percolation at page 462. It has been objected to this process that it yields tinctures of variable strength, according to the skill with which it is conducted; but, from numerous experiments performed, in reference to this point, by H. Buignet of Paris, it appears that the tinctures made by percolation are quite as equable in strength as those prepared by maceration, while they uniformly contain more of the soluble matter of the drug in proportion to the quantity of menstruum. The same writer states that he has constantly found three parts of alcohol, used in this method, to one of the material acted on, sufficient to exhaust drugs almost wholly of their soluble matter. He has derived no advantage from the preliminary maceration usually practised. Fairthorne (*A. J. P.*, 1881, p. 308), in the preparation of hydro-alcoholic tinctures, preferred to macerate the ingredients for twenty-four hours alone in the alcohol, then filter, and mix the filtrate with the required quantity of water and percolate the dregs with the mixture. This plan might be of service in the case of a few drugs which are difficult to exhaust of their activity, but it would involve a useless expenditure of labor and time if used in the majority of official tinctures, and precipitation would be more common. It has been contended in opposition to percolation, applied to the preparation of tinctures, that the menstruum is apt to load itself with substances which, after the preparation of the tincture, are deposited, carrying down with them more or less of the active matter, but Vauflart asserts that more than twenty years of observation has demonstrated to him that tinctures by displacement, properly filtered, deposit no more at the end of a certain period than do those prepared by maceration. Besides, upon the same authority, this tendency to deposition may be easily obviated by mixing all the liquids proceeding from the percolation, and allowing the mixture to stand for a day before filtering. The tinctures thus obtained are, he states, richer than those furnished by ordinary maceration, and time produces in them only insignificant changes. (*J. P. C.*, 4e sér., iv. 411, 1866.) Finally, all agree that the percolated tinctures are apt to contain more of the soluble matter of the drug, and the objections resolve themselves altogether into a question of skill on the part of the operator.

The method of making tinctures by diluting fluidextracts, except in a few special cases, is not to be recommended. The menstruum directed for the fluidextract is most frequently not

identical with that used for the tincture, and precipitation of active constituents often ensues when this easy method is employed. Owing to the larger dose of the tinctures, and consequently less degree of concentration, a larger proportion of water can be used in their menstrua than in fluidextracts, and this is a distinct advantage, as tinctures are frequently prescribed in combination with aqueous solutions.

Another mode of exhausting medicines by spirit has been proposed by H. Burton. It consists in suspending in the solvent, immediately under its surface, the solid matter contained loosely in a bag. The liquid in contact with the bag, becoming heavier by impregnation with the matters dissolved, sinks to the bottom; its place is supplied with a fresh portion, which in its turn sinks, and thus a current is established, which continues until the solid substance is exhausted or the liquid saturated. During the maceration the bag should be occasionally raised above the surface of the liquor in the bottle, allowed to drain, and then again immersed. It is asserted that the period of maceration is much shortened in this way. For this mode of preparing tinctures Samuel Gale has proposed the use of a cylindrical stoneware vessel with a diaphragm capable of being supported at different heights by projections from the inner surface of the jar, with corresponding notches in the diaphragm, to permit its easy passage to the lower ledges. The material is to be placed upon the diaphragm and kept covered with the menstruum. (*A. J. P.*, xxii. 381.)

Tinctures prepared by adding alcohol to the expressed juices of plants have been long in use on the continent of Europe, and have been brought into notice in Great Britain. They are sometimes called in England *preserved vegetable juices*. The tinctures of some of the narcotic plants might no doubt be advantageously prepared in this way, as those of conium, hyoscyamus, and belladonna. See *Succus*. Squire and Bentley have paid attention to these preparations. According to Squire, the leaves only of the plants should be used, and, in the case of biennial plants, those exclusively of the second year, and they should be preferably collected when the plant is in full flower. Bentley recommends the following mode of preparation. To the expressed juice, after it has stood for 24 hours and deposited its feculent matter, alcohol sp. gr. 0.838 is to be added in the proportion of one part by measure to four parts of the juice, and after another period of 24 hours the liquor is to be filtered. This proportion of alcohol has been found sufficient for the preservation of the juice, while it causes the precipitation of the suspended mucilaginous matter. But, though these preserved juices are often energetic, yet it is obvious that tinctures prepared from the fresh plant must be still more so, as they contain necessarily not only the soluble active matter of the juice, but also that which, when the juice is expressed, is left in the solid residue of the plant.

Tinctures should be kept in bottles accurately stoppered, in order to prevent evaporation, which might in some instances be attended with serious inconvenience, by increasing their strength beyond the official standard.

Medicines which act in small doses are most conveniently administered in tinctures, as the proportion of alcohol in which they are dissolved is insufficient to produce an appreciable effect. Those which must be given in large doses should be cautiously employed in this form, lest the injury done by the menstruum should more than counterbalance their beneficial operation. This remark is particularly applicable to chronic cases, in which the use of tinctures is apt to lead to the formation of habits of intemperance. The tinctures of the weaker medicines are more frequently given as adjuvants of other remedies than with the view of obtaining their own full effects upon the system.

In the revision of the Pharmacopœia of 1890, wherever practicable, the proportion of drug to finished tincture was made either 20, 15, 10, or 5 per cent. by volume. Progressive pharmacy demands greater uniformity and simplicity in the processes, and hence in the U. S. P. (8th Rev.) practically all of the tinctures have been brought into two classes, 20 and 10 per cent. The potent tinctures which were mainly 15 per cent. in the U. S. P. 1890 have been reduced to 10 per cent. in order to comply with the recommendations of the Conference for the unification of the strength of Potent Remedies which met in Brussels in 1902. These changes caused considerable outcry at first among physicians and pharmacists, but gradually as time has progressed the wisdom of the Committee of Revision in taking this step has been justified. The tinctures from the following drugs were reduced in strength in the U. S. P. (8th Rev.): Aconite, Belladonna leaf, Benzoin (compound), Cannabis Indica, Catechu (now Gambir), Colchicum seed, Digitalis, Gelsemium, Hyoscyamus, Kino, Lobelia, Nux Vomica (slightly), Opium (slightly), Opium, deodorized (slightly), Physostigma, Sanguinaria, Squill, Stramonium, and Veratrum. The strengths of the following were increased: Calumba, Cantharides, Capsicum, Cardamom, Cinnamon, Orange (sweet), Quassia, Rhubarb, Serpentina, Strophanthus, Tolu. Assay processes are in the U. S. P. (8th Rev.) for the following tinctures: Aconite, Belladonna leaves, Cinchona, Colchicum Seed, Hydrastis, Hyoscyamus, Nux Vomica, Opium, Opium (deodorized), Physostigma and Stramonium.

TINCTURÆ HERBARUM RECENTIUM. U. S.

TINCTURES OF FRESH HERBS

(tinc-tū'ræ hēr-bā'rūm rē-cēn'ti-ūm)

Alcoolatures, *Fr. Cod.*; Tincturen von frischen Pflanzen, *G.*

"Tinctures of Fresh Herbs, when not otherwise directed, are to be prepared according to

the following formula: *The Fresh Herb, cut, bruised, or crushed, *five hundred grammes* [or 17 ounces av., 279 grains]; Alcohol, *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Macerate the Herb with the Alcohol in a closed vessel in a moderately warm place during fourteen days, with occasional stirring; then strongly express the liquid and filter it through paper." *U. S.*

This is a general formula introduced for the guidance of the pharmacist in securing some degree of uniformity in this class of tinctures. Tinctures from fresh herbs are coming into use to some extent, and the fresh herb is to be preferred to the dried drug where a very volatile or easily dissociated substance is the active principle. It is evident that the relative strength must vary, however, with the degree of freshness of the drug and the amount of water contained in it, which depends upon the time of collection, the state of the weather when the herb was gathered, and the amount of subsequent exposure to the atmosphere: hence an absolutely uniform relation cannot be obtained. It is asserted that the fresh tinctures of thuja and gelsemium are more active than the tinctures from the dried drug. (*Proc. A. Ph. A.*, 1878, 755.) F. J. B. Quinlan preserves medicinal plants in a fresh state for a reasonable period in the following manner. The herbs in a perfectly fresh state are bruised to a pulp in a mortar, placed in a glass bottle, and well tamped down; the stopper is then forced in so as to exclude every particle of air, and the top encased by beeswax softened by heat. The bottles are then buried in the ground at a depth of three feet. So treated, belladonna, conium, and other herbs have been kept for four months perfectly sweet and fit for pharmaceutical purposes, and it is probable that bottled herbs will keep in this manner for six or even eight months, and perhaps longer. (*Y. B. P.*, 1883, p. 491.)

TRAGACANTHA. *U. S.*, *Br.*

TRAGACANTH

(trä-g-ăn'thă)

"A gummy exudation from *Astragalus gummifer* Labillardière, or from other species of *Astragalus* (Fam. *Leguminosæ*)." *U. S.* "A gummy exudation obtained by incision from *Astragalus gummifer*, *Labill.*, and some other species of *Astragalus*, *Linn.* Known in commerce as Syrian tragacanth." *Br.*

Gummi Tragacanthæ vel Astragalorum; Gomme Adragante, *Fr. Cod.*; Tragacantha, *P. G.*; Tragant, *Tragant*, *G.*; Gomma adragante, *Dragante*, *It.*; Gomo tragacanto, *Sp.*

Numerous species belonging to this genus yield a gummy matter having the properties of tragacanth. The drug known in commerce by that name was at first erroneously supposed to be obtained from *A. Tragacantha* of Linnaeus (*A. massiliensis* of Lamarek), which

grows in Southern Europe and Northern Africa and is now said to yield no gum. It was afterwards ascribed, on the authority of Tournefort, to a species (*A. creticus* of Lamarek) which grows in Crete and Ionia, and on that of Olivier, to *A. verus*, which inhabits Asia Minor, Armenia, and Northern Persia. Labillardière described a species by the name of *A. gummifer* which he found growing on Mount Libanus in Syria, and from which tragacanth exudes, though not that of commerce.

Sieber denies that any of the above-mentioned species yields the official tragacanth, which he ascribes to *A. aristatus*, growing in Anatolia especially upon Mount Ida, where the gum is most abundantly collected. This plant, however, is not the *A. aristatus* of Villars, which, according to Sibthorp, furnishes tragacanth in Greece. (Mérat and De Lens.) Lindley received two specimens of plants, said to be those which furnish tragacanth in Turkestan, one of which proved to be *A. gummifer* of Labillardière which was said to yield a white variety, and the other a new species, which he called *A. strobiliferus*, and which was said to yield a red and inferior product. The fact seems to be that the commercial drug is collected from various sources; and it is affirmed that all the species of *Astragalus* with thorny petioles are capable of producing it. These form a natural group, and so closely resemble one another that botanists have found some difficulty in distinguishing them. They are very abundant on the mountains of Asia Minor, and, according to information received by M. J. Léon Soubeiran from Balansa, a scientific traveller who derived his knowledge from personal observation, the gum-producing species are closely analogous to the *A. creticus* of Lamarek. It is in the *Anti-Taurus* range that the gum is chiefly collected. Transverse incisions are made, near the base of the stem, into the medullary part, which alone yields juice. This exudes very slowly, flowing at night, and ceasing during the day; two weeks usually elapse before the pieces are large enough for collection. The shape of the pieces is influenced by the rapidity of the exudation, and the lines on their surface indicate the daily concretion. The section *Tragacantha* of the genus *Astragalus* includes the principal species which yield gum tragacanth.

According to Haussknecht, tragacanth is yielded by the following species of *Astragalus*: *A. adscendens*, Boiss. et Hausskn. (Southern Persia); *A. leioclados*, Boiss. (in Middle and Western Persia, by Ispahan and Hamadan); *A. brachycalyx*, Fisch. (Kurdistan and Luristan); *A. gummifer*, Labill. (widely distributed from Lebanon to Armenia and in the northern regions of the Euphrates and Tigris); *A. microcephalus*, Willd. (the same as *A. gummifer*, Labill., and also in Asia Minor); *A. pycnocladus*, Boiss. et Hausskn. (particularly in Western Persia); *A. stromatodes*, Bge. (in

Achyr Dagh, in Northern Syria); *A. kurdicus*, Boiss. (Aintab). Other species that yield a tragacanth gum are *A. heratensis*, Bge., of the Khorasan Mountains, which yields a gum known as "kutira," and *A. Parnassi*, Boiss., var. *cyllenea*, found on the mountains of Peloponnesus.

Properties.—Tragacanth is odorless and nearly tasteless. It occurs either in flaky, leaf-like pieces, irregularly oblong or roundish, or in tortuous vermicular filaments, rounded or flattened, rolled up or extended, of a whitish, yellowish-white, or slightly reddish color, marked by parallel lines or ridges, somewhat translucent, and resembling horn in appearance. In commerce certain varieties of tragacanth are recognized and usually known by the name of the locality from which they have been produced or through which they have entered commerce. The ordinary tragacanth, tragacanth in sorts, sometimes known as *traganton*, occurs in irregular pieces; Smyrna tragacanth appears usually in broad thick flakes, yellowish or brownish; Syrian tragacanth, in thin, ribbon-like, white flakes, is said really to be obtained in Kurdistan and Persia. Tragacanth is officially described as "in ribbon-shaped bands varying in size and from 1 to 3 Mm. thick, or in irregular pieces of the same, long and linear, straight or spirally twisted; externally whitish, marked by more or less pronounced longitudinal or excentric lines or ridges; translucent, horny, fracture short, tough, rendered more easily pulverizable by a heat of 50° C. (122° F.). On treating Tragacanth with 50 parts of water, it swells and gradually forms a cloudy, gelatinous mass, which, on warming with solution of sodium hydroxide on a water-bath, becomes yellow and is tinged blue on the addition of iodine T.S.; the addition of alcohol to the fluid portion causes a precipitate, but the liquid is not colored blue by iodine T.S." *U. S.*

It is hard and more or less fragile, but difficult of pulverization, unless exposed to a freezing temperature, or thoroughly dried, and powdered in a heated mortar at the temperature of 50° C. (122° F.). Its sp. gr. is 1.384. Introduced into water, it absorbs a certain proportion of that liquid, swells very much, and forms a soft adhesive paste, but does not dissolve. If agitated with an additional quantity of water, this paste forms a uniform mixture; but in the course of one or two days the greater part separates, and is deposited, leaving a portion dissolved in the supernatant fluid. Tragacanth is wholly insoluble in alcohol. It appears to be composed of two different constituents, one soluble in water and resembling gum arabic, the other swelling in water, but not dissolving. To separate the soluble from the insoluble part requires agitation with separate portions of water; the solutions are to be decanted and filtered, and the process is to be continued until water ceases to dissolve anything.

Von Sandersleben reported the discovery that when heated with dilute acids tragacanth acquired reducing properties, and formed, along with much syrup, *arabinose*, which crystallized. (Tollens, *Handbuch der Kohlenhydrate*, 1888, 218.) The explanation of this observation, now generally accepted, is that in tragacanth, like some other gums, part of the arabic acid is present in soluble form, mostly combined with bases, while another part is present in insoluble form, and is known as *iraganthin*. This latter, however, under the influence of certain enzymes, is converted into the soluble form. (Lippmann, *Chemie der Zuckerarten*, 2te Auf., 1895, 925.) C. O'Sullivan states that tragacanth consists of *cellulose*, the portion insoluble in boiling water, cold dilute acids, and alkalies; also *soluble gum*, yielding a series of gum acids of the nature of *geddic acid*, and which are called *polyarabinontrigalactan-geddic acids*; *starch granules*; *bassorin*, which yields *a-tragacanthan-xylan-bassoric acid*, *xylan-bassoric acid* and *bassoric acid*. (*Proc. Chem. Soc.*, 1901.) Examined by Kützing by means of the microscope, tragacanth was found to consist of organized cells. (See *A. J. P.*, xxv. 37.) In conformity with this statement is the remarkable fact, discovered by Hugo von Mohl and confirmed by Wigand, that tragacanth is not a secretion of the plant, but the result of the transformation of the cells of the pith and those of the medullary rays which traverse the ligneous part of the stem and older branches. (*Ibid.*, xxxi. 243.)

It is stated by S. H. Maltass that tragacanth is adulterated, in the Levant, with worthless gums brought from Armenia and Caramania, which, as they are originally of a dark color and destitute of the flaky form of the genuine gum, are broken into small fragments and whitened by means of lead carbonate before being mixed with the tragacanth. Hanbury states, in confirmation of this, that he has detected lead in the *small tragacanth* imported into London. (*P. J.*, xv. 20.)

Uses.—Tragacanth is demulcent, but, on account of its difficult solubility, is not often given internally. The great viscosity which it imparts to water renders it useful for the suspension of heavy insoluble powders, and it is also employed in pharmacy to impart consistence to troches, for which it answers better than does gum arabic, and in making emulsions, although for these purposes it is inferior to acacia.

Off. Prep.—*Confectio Sulphuris, Br.*; *Emulsum Chloroformi, U. S.*; *Glycerinum Tragacanthæ, Br.*; *Mistura Cretæ, Br.*; *Mistura Guaiaci, Br.*; *Mucilago Tragacanthæ, U. S., Br.*; *Pilulæ Ferri Carbonatis, U. S. (Br.)*; *Pilula Quinina Sulphatis, Br.*; *Pulvis Opii Compositus, Br.*; *Pulvis Tragacanthæ Compositus, Br.*; *Trochisci Acidi Tannici, U. TRITICUM. U. S.

TRITICUM [Couch Grass]

(trīt'ī-cūm)

"The dried rhizome of *Agropyron repens* (Linné) Beauvois (Fam. *Gramineæ*), gathered in the spring." U. S.

Agropyrum, Br. *Add.*; *Rhizoma Graminis*; *Radix Graminis*; Couch-grass, Quick-grass, Quitch, Dog-grass, Scotch-grass, Twitch-grass, Witch-grass, Quick-ens; Chiendent officinal ou Petit chiendent, *Fr. Cod.*; Queckenwurz, Grasswurz, *G.*; Grama (*Rizoma de*), *Sp.*

This grass, originally a native of Europe, now abounds in meadows and cultivated grounds in the Northern United States, where it is often very troublesome as a weed. It is specifically characterized by its creeping root-stock, by its awns being absent or not more than half the length of the flower, and by its rough, flat leaves. It is probable that the rhizome of a number of other grasses share the medicinal properties of *Agropyron repens*. Of these the Scotch or Bermuda grass, *Capriola Dactylon* (L.), Kuntze, is probably as effective as the official species.

Properties.—Triticum is officially described as follows: "Of horizontal growth, subcylindrical, 1 to 2 Mm. in diameter, usually cut into sections 5 to 8 Mm. long; externally brownish-yellow to straw-colored, nearly smooth; hollow in the centre; odor slight; taste distinctly sweet." U. S.

Uses.—Triticum is never exhibited for the purpose of affecting the general system, but only for its influence upon the genito-urinary organs. It is much used by some surgeons in irritable bladder, and also in cystitis. It is one of the least stimulant of the remedies of its class, and may be employed very freely. In Europe its decoction is said to be used to a considerable extent as a diluent and slightly nutritious drink. It may be taken *ad libitum*, or the fluidextract may be given in doses of a fluidrachm (3.75 Ce.) every three hours in five or six ounces of water.

TRITURATIO ELATERINI. U. S. (Br.)

TRITURATION OF ELATERIN

(trīt-ù-rā'tī-ō ēl-ā-tē-rī'nī)

Pulvis Elaterini Compositus, Br.; Compound Powder of Elaterin; Trituration d'Elatérine, *Fr.*; Elaterintrituration, *G.*

*"Elaterin, *ten grammes* [or 154 grains]; Sugar of Milk, in moderately fine powder, *ninety grammes* [or 3 ounces av., 76 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Mix them thoroughly by trituration." U. S.

"Elaterin, 5 grains or 1 gramme; Milk Sugar, 195 grains or 39 grammes. Triturate in a mortar until a fine powder is produced." Br.

The Br. Pharm. 1898 added the Compound Powder of Elaterin to the list of powders. It is identical with the Trituration of Elaterin, except in strength. The U. S. P. trituration contains 10 per cent. of elaterin, the British powder 2½ per cent.

This is probably the best representative of the class of triturations that could be selected for introduction into the national authority. Elaterium is at best a substance of variable quality, while the active principle is a definite product, and accurate dosage can be secured more effectually through the use of this trituration than by the employment of commercial elaterium.

Dose, from one-fourth to five-eighths of a grain (0.016 to 0.04 Gm.). The dose of the British powder is from one to four grains (0.065 to 0.26 Gm.).

TRITURATIONES. U. S.

TRITURATIONS

(trīt-ù-rā-tī-ō'nēs)

Triturations, *Fr.*; Triturationen, *G.*

"Unless otherwise directed, Triturations are to be prepared according to the following formula. *Take of the Substance, *ten grammes* [or 154 grains]; Sugar of Milk, in moderately fine powder, *ninety grammes* [or 3 ounces av., 76 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Weigh the Substance and the Sugar of Milk, separately; then place the Substance, previously reduced, if necessary, to a moderately fine powder, in a mortar; add about an equal measure of Sugar of Milk, mix well by means of a spatula, and triturate the powders thoroughly together. Then add fresh portions of Sugar of Milk, from time to time, until the whole is added, and continue the trituration after each addition until the Substance is intimately mixed with the Sugar of Milk and reduced to a fine powder." U. S.

This general formula has been introduced into the Pharmacopœia in order that a definite and uniform method be authorized of making a class of powders which has come into use in various sections of our country. While the necessity of giving recognition to the class may be questioned by many, the importance of securing uniformity in composition is evident.

TROCHISCI.

TROCHES

(trō-phis'ei)

Tabellæ; Lozenges; Tablettes, *Fr. Cod.*; Pastilli, Rotulæ, *P. G.*; Pastillen, Plätzchen, Tabletten, *G.*; Pastiglie, *It.*; Tabletās, *Sp.*

Troches or lozenges are small, dry, solid masses, usually of a flattened shape, consisting for the most part of powders incorporated with sugar and mucilage. They are designed

to be held in the mouth and dissolved slowly in the saliva, and are, therefore, adapted for the administration of those medicines only which do not require to be given in large quantities and which are destitute of any very disagreeable flavor.

Lozenges were formerly much more used and more skilfully prepared in Europe than in this country, but at present those manufactured here are fully equal to the imported lozenges. Tragacanth, from the greater tenacity of its mucilage, is better suited for their formation than gum arabic. The following directions for preparing them are taken from the *Dictionnaire des Drogues*. A mucilage of tragacanth is first prepared with cold water and strained. With this the powders, including sugar, are thoroughly mixed by rubbing upon a marble slab, and are thus formed into a paste, which is spread out by means of a roller upon the surface of the marble, previously powdered over with a mixture of sugar and starch. The thickness of the mass is rendered uniform by a frame upon which the ends of the roller rest. The upper surface is now dusted with sugar and starch, and the mass is divided into small cakes by means of a punch. These cakes are placed upon paper, and, having been exposed to the air for twelve hours, are carried into a drying room moderately heated. When perfectly dry, they are thrown upon a sieve to separate the sugar and starch, and are then enclosed in boxes. Lozenges may be prepared from almost any medicine which it is advisable to administer in this form. The following typical formula may be found useful.

Take citric acid, in powder, a drachm; powdered sugar eight ounces; oil of lemon twelve minims; mucilage of tragacanth a sufficient quantity. Form them in the manner above directed into troches of twelve grains each. Lozenges are sometimes made by saturating blank lozenges with aromatic spirits. Currant paste or jelly has come into use of late years largely as a basis for troches.¹

¹ *Currant Paste Lozenges*.—These lozenges have been largely employed. They were introduced by Morell Mackenzie, Senior Physician to the London Hospital for Diseases of the Throat, and differ from ordinary lozenges in the use as a basis of currant paste (or jelly), of which they contain from 70 to 80 per cent.; this may usually be obtained from wholesale confectioners or grocers.

Trochisci Acidi Benzoici.—Benzolic Acid, in powder, 175 grains; Tragacanth, in powder, 70 grains; Refined Sugar, in powder, 280 grains; Red Currant Paste, as much as is sufficient. Mix the dry ingredients; then add the Red Currant Paste until the whole mass weighs 1 pound; divide into 350 lozenges of 20 grains each, and dry them in a hot-air chamber at a moderate heat. Each lozenge contains about one-half grain of Benzoic Acid, and is marked B. A. Dose, one lozenge every four hours. If used as a "voice lozenge," one should be taken a quarter of an hour before using the voice.

Trochisci Acidi Carbolic.—Pure Carbolic Acid, 350 grains; Gum Acacia, in powder, 220 grains; Refined Sugar, in powder, 5468 grains (12½ ounces); Mucilage of Gum Acacia, 1 ounce; Distilled Water, as much as is sufficient. Mix the Carbolic Acid with the powders, add the Mucilage and Water to form a mass weighing 1 pound, and divide into 350 lozenges and dry them in a hot-air chamber at a moderate heat. Each lozenge contains about one grain of Carbolic

Lozenges of a cylindrical shape are extensively used, having a basis of licorice, gum, and sugar, and the manufacture of these is now an im-

Acid, and is marked C. A. Dose, one lozenge four or five times daily. Use, antiseptic and stimulant.
Trochisci Acidi Tannici.—Tannic Acid, in powder, 525 grains; Tragacanth, in powder, 70 grains; Refined Sugar, in powder, 280 grains; Black Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici*.) Each lozenge contains 1½ grains of Tannic Acid, and is marked T. Dose, one lozenge every three or four hours.

Trochisci Aconiti.—Tincture of Aconite (B. P. 1885) 175 minims; Tragacanth, in powder, 70 grains; Refined Sugar, in powder, 280 grains; Black Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici*.) Each lozenge contains the equivalent of half a minim of Tincture of Aconite (B. P. 1885) (or five-eighths of a minim, U. S. P. 8th Rev.), and is marked A. C. Dose, one lozenge every half-hour or hour. Use, in tonsillitis and febrile affections of the throat.

Trochisci Althææ.—Powdered decorticated Marsh-mallow Root, 400 grains; Refined Sugar, in powder, ¼ pound; Gum Acacia, in powder, ½ pound; Orange Flower Water and White of Egg, as much as is sufficient to make into 350 soft lozenges. Macerate the Marsh-mallow Root in a sufficient quantity of Orange Flower Water for 12 hours, strain, then add the Gum Acacia and Sugar; dissolve, and evaporate to the consistence of honey with constant stirring; add gradually the White of Egg beaten up with more Orange Flower Water. Evaporate, with stirring, till the paste will not adhere to the hand; then divide into lozenges. Dose, one lozenge every half-hour or hour. Use, emollient. Valuable after excision of tonsils or uvula.

Trochisci Ammonii Chloridi.—Ammonium Chloride, in powder, 700 grains; Tragacanth, in powder, 140 grains; Refined Sugar, in powder, 280 grains; Black Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici*.) Each lozenge contains about 2 grains of Ammonium Chloride, and is marked M. A. Dose, one lozenge every three hours.

Trochisci Boracis.—Borax, in powder, 1050 grains; Tragacanth, in powder, 140 grains; Refined Sugar, in powder, 280 grains; Black Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici*.) Each lozenge contains 3 grains of Borax, and is marked B. O. Dose, one lozenge every three or four hours.

Trochisci Catechu.—Pale Catechu, 700 grains; Tragacanth, in powder, 70 grains; Refined Sugar, in powder, 280 grains; Black Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici*.) Each lozenge contains 2 grains of Catechu, and is marked C. T. Dose, one lozenge every three hours. Use, astringent, but less powerful than the Tannic Acid Troches.

Trochisci Cubebe.—Cubebs, in powder, 200 grains; Extract of Liquorice, 122 grains; Tragacanth, in powder, 70 grains; Refined Sugar, 200 grains; Black Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici*.) Each lozenge contains about one-half grain of Cubebs, and is marked C. B. Dose, one lozenge every three or four hours. Use, very serviceable in diminishing excessive secretion of mucus from pharynx, larynx, or trachea. These lozenges closely resemble the *Brown's Bronchial Troches*, but Black Currant Paste is employed, and less gum and sugar.

Trochisci Gualacis.—Gualacum Resin, in powder, 700 grains; Tragacanth, in powder, 70 grains; Refined Sugar, in powder, 280 grains; Black Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici*.) Each lozenge contains 2 grains of Gualacum, and is marked G. Dose, one lozenge every two hours in acute inflammation; three times a day in chronic affections. Use, a specific for arresting crescent inflammation of the tonsils, and useful both in acute and subacute inflammation of the pharynx, and in acute follicular disease of the tonsils, etc.

Trochisci Kino.—Kino, in powder, 700 grains; Tragacanth, in powder, 70 grains; Refined Sugar, in powder, 280 grains; Black Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici*.) Each lozenge contains 2 grains of Kino, and is marked K. Dose, one lozenge every three or four hours. Use, astringent; rather less powerful than Rhatany.

Trochisci Kramerie.—Extract of Rhatany, in powder, 1050 grains; Tragacanth, in powder, 70 grains; Refined Sugar, in powder, 280 grains; Red Currant Paste, as much as is sufficient. Mix and divide into

portant industry. Franklin C. Hill devised an improved machine for making Licorice and Wistar's Lozenges. (See *A. J. P.*, 1874, 401.) For Slocum's and Harrison's improved forms of lozenge boards, rollers, etc., see *A. J. P.*, 1879, 589; 1880, 255. A. D. Marcy figured an instrument for shaping troches in *N. R.*, Feb. 1882.

The Br. Pharmacopœia 1898 adopted four bases for lozenges, as follows: fruit basis, rose basis, simple basis, and tolu basis. It will be noticed that in the British formulas the quantity of active ingredients for each lozenge is stated and the kind of basis indicated. This is done merely to avoid repetition.

PREPARATION WITH FRUIT BASIS.

"Take five hundred times the quantity of the drug ordered for one lozenge; mix it intimately with *fifteen and a half ounces* (Imperial) or four hundred and thirty-nine and a half grammes of Refined Sugar, in fine powder, and *three hundred grains* or nineteen and a half grammes of Gum Acacia, in powder. Make the mixture into a paste with *one fluid*

ounce and a quarter (Imp. meas.) or thirty-five and a half cubic centimetres of Mucilage of Gum Acacia and *two ounces* (Imp.) or fifty-six and three-quarter grammes of the black-currant paste of commerce previously softened with boiling Distilled Water, adding any additional Distilled Water that may be necessary. Divide the mass into five hundred equal lozenges. Dry them in a hot-air chamber at a moderate temperature." *Br.*

PREPARATION WITH ROSE BASIS.

"Take five hundred times the quantity of the drug ordered for one lozenge; mix it intimately with *seventeen and a half ounces* (Imperial) or four hundred and ninety-six grammes of Refined Sugar, in fine powder, and *three hundred grains* or nineteen and a half grammes of Gum Acacia, in powder. Make the mixture into a paste with *five fluid drachms* (Imp. meas.) or seventeen and a half cubic centimetres of Mucilage of Gum Acacia and a sufficient quantity of the official Rose Water. Divide the mass into five hundred lozenges. Dry them in a hot-air chamber at a moderate temperature." *Br.*

PREPARATION WITH SIMPLE BASIS.

"Take five hundred times the quantity of the drug ordered for one lozenge; mix it intimately with *seventeen and a half ounces* (Imperial) or four hundred and ninety-six grammes of Refined Sugar, in fine powder, and *three hundred grains* or nineteen and a half grammes of Gum Acacia, in powder. Make the mixture into a paste with *one fluid ounce and a quarter* (Imp. meas.) or thirty-five and a half cubic centimetres of Mucilage of Gum Acacia and a sufficient quantity of Distilled Water. Divide the mass into five hundred equal lozenges. Dry them in a hot-air chamber at a moderate temperature." *Br.*

PREPARATION WITH TOLU BASIS.

"Take five hundred times the quantity of the drug ordered for one lozenge; dissolve what salts of alkaloids may be ordered in *three fluid drachms* (Imperial measure) or ten and a half cubic centimetres of Distilled Water; mix the solution intimately with *seventeen ounces* (Imp.) or four hundred and eighty-two grammes of Refined Sugar, in fine powder, and *three hundred grains* or nineteen and a half grammes of Gum Acacia, in powder. Thoroughly incorporate with the mixture any other drugs ordered for the lozenges, and *three fluid drachms* (Imp. meas.) or ten and a half cubic centimetres of Tincture of Balsam of Tolu. Make into a paste with *one fluid ounce and a quarter* (Imp. meas.) or thirty-five and a half cubic centimetres of Mucilage of Gum Acacia and any additional Distilled Water that may be necessary. Divide the mass into five hundred equal lozenges. Dry them in a hot-air chamber at a moderate temperature." *Br.*

350 lozenges. (See *Trochisci Acidi Benzoici*.) Each lozenge contains 3 grains of Extract of Rhatany, and is marked R. Dose, one lozenge every three or four hours. Use, a very useful astringent. Rhatany does not disagree with the stomach, as is often the case with Tannic Acid, nor does it cause constipation to the same extent as Kino or Catechu.

Trochisci Lactuce.—Extract of Lettuce, 350 grains; Tragacanth, in powder, 100 grains; Refined Sugar, in powder, 280 grains; Black Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici*.) Each lozenge contains 1 grain of Extract of Lettuce, and is marked L. Dose, one lozenge every hour or two. Use, soothing and mildly sedative.

Trochisci Potassii Chloratis.—Potassium Chlorate, in powder, 1050 grains; Tragacanth, in powder, 140 grains; Refined Sugar, in powder, 280 grains; Black Currant Paste, sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici*.) Each lozenge contains 3 grains of Potassium Chlorate, and is marked P. Dose, one lozenge every three or four hours. Use, stimulant and antiseptic. Useful in thrush and aphthous ulceration.

Trochisci Potassii Citratis.—Potassium Citrate, in powder, 1050 grains; Tragacanth, in powder, 140 grains; Refined Sugar, in powder, 280 grains; Red Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici*.) Each lozenge contains 3 grains of Potassium Citrate, and is marked C. P. Dose, one lozenge every three or four hours. Use, topical sialagogue.

Trochisci Potassii Tartratis Acidæ.—Acid Potassium Tartrate, 1050 grains; Tragacanth, in powder, 140 grains; Refined Sugar, in powder, 280 grains; Red Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici*.) Each lozenge contains 3 grains of Acid Potassium Tartrate, and is marked T. P. Dose, one lozenge every two or three hours. Use, topical sialagogue.

Trochisci Pyllethri.—Pellitory Root, in powder, 350 grains; Tragacanth, in powder, 70 grains; Refined Sugar, in powder, 280 grains; Black Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici*.) Each lozenge contains 1 grain of Pellitory, and is marked P. Y. Dose, one lozenge every two or three hours. Use, a very valuable sialagogue.

Trochisci Sedativi.—Extract of Opium, in powder, 35 grains; Tragacanth, in powder, 100 grains; Refined Sugar, in powder, 280 grains; Black Currant Paste, as much as is sufficient. Prepare and divide into 350 lozenges. (See *Trochisci Acidi Benzoici*.) Each lozenge contains one-tenth grain of Extract of Opium, and is marked S. Dose, one lozenge every three or four hours. Use, sedative, for irritative coughs and painful conditions of the pharynx. (From the *Pharmacopœia of the Hospital for the Diseases of the Throat*, 4th edition.)

The following official troches of the U. S. P. 1890 were not retained in the U. S. P. (8th Rev.): Trochisci Cretæ, Ferri, Ipecacuanhæ, Menthæ Piperitæ, Morphinæ et Ipecacuanhæ, Zingiberis. Troches of Catechu were replaced by Troches of Gambir.¹

¹ *Trochisci Cretæ*. U. S. 1890. *Troches of Chalk*.—"Prepared Chalk, twenty-five grammes [or 386 grains]; Acacia, in fine powder, seven grammes [or 108 grains]; Spirit of Nutmeg, three cubic centimeters [or 49 minims]; Sugar, in fine powder, forty grammes [or 1 ounce av., 180 grains]; Water, a sufficient quantity, to make one hundred troches. Rub the powders with the Spirit of Nutmeg until they are thoroughly mixed; then, with Water, form a mass, to be divided into one hundred troches." U. S. 1890.

These troches contain each about four grains (0.25 Gm.) of chalk, and are used as a gentle, astringent antacid in *diarrhæa*. They deserve to be used more frequently than they have been, being well adapted for children.

Trochisci Ferri. U. S. 1890. *Troches of Iron*.—"Ferric Hydrate, dried at a temperature not exceeding 80° C. (176° F.), thirty grammes [or 1 ounce av., 25 grains]; Vanilla, cut into slices, one gramme [or 15 grains]; Sugar, in fine powder, one hundred grammes [or 3 ounces av., 231 grains]; Mucilage of Tragacanth, a sufficient quantity, to make one hundred troches. Rub the Vanilla, first, with a portion of the Sugar to a uniform powder, and afterwards with the Ferric Hydrate and the remainder of the Sugar, until they are thoroughly mixed. Then, with Mucilage of Tragacanth, form a mass, to be divided into one hundred troches." U. S. 1890.

Each lozenge contains about five grains (0.3 Gm.) of ferric hydrate, and from one to six may be given, according to the effects desired. (See *Ferri Oxidum Hydratum*.)

Trochisci Ipecacuanhæ. U. S. 1890. *Troches of Ipecac*.—"Ipecac, in No. 60 powder, two grammes [or 31 grains]; Tragacanth, in fine powder, two grammes [or 31 grains]; Sugar, in fine powder, sixty-five grammes [or 2 ounces av., 128 grains]; Syrup of Orange, a sufficient quantity, to make one hundred troches. Rub the powders together until they are thoroughly mixed; then, with Syrup of Orange, form a mass, to be divided into one hundred troches." U. S. 1890.

Trochisci Menthæ Piperitæ. U. S. 1890. *Troches of Peppermint*.—"Oil of Peppermint, one cubic centimeter [or 16 minims]; Sugar, in fine powder, eighty grammes [or 2 ounces av., 360 minims]; Mucilage of Tragacanth, a sufficient quantity, to make one hundred troches. Rub the Oil of Peppermint and the Sugar together until they are thoroughly mixed; then, with Mucilage of Tragacanth, form a mass, to be divided into one hundred troches." U. S. 1890.

Useful in slight gastric or intestinal pains, nausea, and flatulence.

Trochisci Morphinæ et Ipecacuanhæ. U. S. 1890. *Troches of Morphine and Ipecac*.—"Morphine Sulphate, sixteen centigrammes [or 2½ grains]; Ipecac, in No. 60 powder, fifty centigrammes [or 8 grains]; Sugar, in fine powder, sixty-five grammes [or 2 ounces av., 128 grains]; Oil of Gaultheria, two-tenths of a cubic centimeter [or 3 minims]; Mucilage of Tragacanth, a sufficient quantity, to make one hundred troches. Rub the powders together until they are thoroughly mixed; then add the Oil of Gaultheria (equivalent to about 4 drops), and incorporate it with the mixture. Lastly, with Mucilage of Tragacanth, form a mass, to be divided into one hundred troches." U. S. 1890.

Expectorant and anodyne, useful especially in *allaying cough*. The U. S. 1890 lozenges contained one-fortieth of a grain (0.0016 Gm.) of morphine salt, and one-twelfth of a grain (0.005 Gm.) of ipecac.

Trochisci Zingiberis. U. S. 1890. *Troches of Ginger*.—"Tincture of Ginger, twenty cubic centimeters [or 325 grains]; Tragacanth, in fine powder, four grammes [or 62 grains]; Sugar, in fine powder, one hundred and thirty grammes [or 4 ounces av., 256 grains]; Syrup of Ginger, a sufficient quantity, to make one hundred troches. Mix the Tincture of Ginger with the Sugar, and, having exposed the mixture to the air until dry, reduce it to a fine powder. To this add the Tragacanth, and mix thoroughly. Lastly, with Syrup of Ginger, form a mass, to be divided into one hundred troches." U. S. 1890.

Each lozenge contains three minims (0.2 Cc.) of the tincture, and they may be taken as required, being especially calculated to relieve gastric pains resulting from flatulence.

TROCHISCUS ACIDI BENZOICI. Br.

BENZOIC ACID LOZENGE

(trō-phis'cūs āç'i-dī bēn-zō'i-ci)

Tablettes de l'Acide Benzoïque, *Fr.*; Benzoësapastillen, *G.*

"Benzoic Acid, $\frac{1}{2}$ grain or 0.0324 gramme. Mix with the Fruit Basis to form a Lozenge." *Br.* (See p. 1298.)

TROCHISCUS ACIDI CARBOLICI. Br.

PHENOL LOZENGE

(trō-phis'cūs āç'i-dī cār-bō'l'i-ci)

Tablettes de l'Acide Phénique, *Fr.*; Phenolpastillen, *G.*

"Phenol, 1 grain or 0.0648 gramme. Mix with the Tolu Basis to form a Lozenge." *Br.* (See p. 1298.)

TROCHISCI ACIDI TANNICI. U. S. (Br.)

TROCHES OF TANNIC ACID.

(trō-phis'ci āç'i-dī tān-nī-ci)

Trochiscus Acidii Tannici, *Br.*; Tannin Lozenges; Tablettes de Tannin, *Fr.*; Tanninpastillen, *G.*

* "Tannic Acid, six grammes [or 93 grains]; Sugar, in fine powder, sixty-five grammes [or 2 ounces av., 128 grains]; Tragacanth, in fine powder, two grammes [or 31 grains]; Stronger Orange Flower Water, a sufficient quantity, to make one hundred troches. Rub the powders together until they are thoroughly mixed; then, with Stronger Orange Flower Water, form a mass, to be divided into one hundred troches." U. S.

"Tannic Acid, $\frac{1}{2}$ grain or 0.0324 gramme. Mix with the Fruit Basis to form a Lozenge." *Br.* (See p. 1298.)

These are useful in *relaxation of the uvula*, and in *chronic angina*, being allowed slowly to dissolve in the mouth. Each U. S. troche contains about one grain (0.065 Gm.) of the acid.

TROCHISCI AMMONII CHLORIDI. U. S.

TROCHES OF AMMONIUM CHLORIDE

(trō-phis'ci ām-mō'nī-i çhlō'rī-dī)

Tablettes de Chlorhydrate d'Ammoniaque, *Fr.*; Chlorammoniumpastillen, *G.*

* "Ammonium Chloride, in fine powder, ten grammes [or 154 grains]; Extract of Glycyrrhiza, in fine powder, twenty grammes [or 309 grains]; Tragacanth, in fine powder, two grammes [or 31 grains]; Sugar, in fine powder, forty grammes [or 1 ounce av., 180 grains]; Syrup of Tolu, a sufficient quantity, to make one hundred troches. Rub the powders together until they are thoroughly mixed; then, with Syrup of Tolu, form a mass, to be divided into one hun-

dred troches." U. S. Each troche contains about one and a half grains (0.096 Gm.) of ammonium chloride.

These troches are largely used in congested conditions of the pharynx and larynx.

TROCHISCUS BISMUTHI COMPOSITUS.

Br.

COMPOUND BISMUTH LOZENGE

(trɔ-phis'cūs biş-mū'thī cəm-pōş'i-tūs)

Troches of Bismuth; Tablettes de Sous-nitrate de Bismuth, *Fr. Cod.*; Wismuthpastillen, *G.*

"Bismuth Oxycarbonate, 2 grains or 0.1296 gramme; Heavy Magnesium Carbonate, 2 grains or 0.1296 gramme; Precipitated Calcium Carbonate, 4 grains or 0.2592 gramme. Mix with the Rose Basis to form a Lozenge." *Br.* (See p. 1298.)

These may be used to obtain the effects of bismuth subcarbonate on the stomach, as well as of the magnesium and calcium carbonates as an antacid, two or more being administered for a dose. They may also be found useful in chronic inflammation of the throat and œsophagus.

TROCHISCI CUBEÆ. U. S.

TROCHES OF CUBE

(trɔ-phis'cī cū-bē'bæ)

Tablettes de Cubèbe, *Fr.*; Kubebenpastillen, *G.*

* "Oleoresin of Cubebe, two grammes [or 31 grains]; Oil of Sassafras, one cubic centimeter [or 16 minims]; Extract of Glycyrrhiza, in fine powder, twenty-five grammes [or 386 grains]; Acacia, in fine powder, twelve grammes [or 185 grains]; Syrup of Tolu, a sufficient quantity, to make one hundred troches. Rub the powders together until they are thoroughly mixed; then add the Oleoresin and the Oil, and incorporate them with the mixture. Lastly, with Syrup of Tolu, form a mass, to be divided into one hundred troches." U. S.

Each lozenge contains one-fourth of a minim (0.02 Gm.) of the oleoresin of cubebe, being about one-fourth the strength of the lozenge of 1870, and one-half the strength of the 1890 troches. The preparation is intended chiefly for effect upon the fauces and other parts of the upper alimentary passages, and may be used advantageously in some cases of chronic cough, and in ulceration or chronic inflammation of the fauces.

TROCHISCUS EUCALYPTI GUMMI. Br.

EUCALYPTUS GUM LOZENGE

(trɔ-phis'cūs eū-ēā-lŷp'tī gūm'ni)

Tablettes de Kino d'Eucalypte, *Fr.*; Eucalyptus-kino-pastillen, *G.*

"Eucalyptus Gum, 1 grain or 0.0648 gramme. Mix with the Fruit Basis to form a Lozenge." *Br.* (See p. 1298.)

TROCHISCUS FERRI REDACTI. Br.

REDUCED IRON LOZENGE

(trɔ-phis'cūs fēr'rī rē-dāc'ti)

Tablettes de Fer Réduit par l'Hydrogène, Tablettes de Fer, *Fr.*; Eisenpastillen, *G.*

"Reduced Iron, 1 grain or 0.0648 gramme. Mix with the Simple Basis to form a Lozenge." *Br.* (See p. 1298; also page 518.)

From one to five of the lozenges may be taken for a dose.

TROCHISCI GAMBIR. U. S. (Br.)

TROCHES OF GAMBIR

[To replace Trochisci Catechu, *Pharm.*, 1890, Troches of Catechu]

(trɔ-phis'cī gām'bīr)

Trochiscus Catechu, *Br.*, Catechu Lozenge; Tabellæ cum Catechu; Tablettes de Cachou, *Fr. Cod.*; Katechupastillen, *G.*

* "Gambir, in fine powder, six grammes [or 93 grains]; Sugar, in fine powder, sixty-five grammes [or 2 ounces av., 128 grains]; Tragacanth, in fine powder, two grammes [or 31 grains]; Stronger Orange Flower Water, a sufficient quantity, to make one hundred troches. Rub the powders together until they are thoroughly mixed; then, with Stronger Orange Flower Water, form a mass, to be divided into one hundred troches." U. S.

"Catechu, 1 grain or 0.0648 gramme. Mix with the Simple Basis to form a Lozenge." *Br.* (See p. 1298.)

These, like the troches of tannic acid, are useful in prolapsus of the uvula, and in other forms of relaxation of the fauces, and may also be used, in the number of three or more at a dose, to obtain the effects of catechu or gambir on the *primæ viæ* and on the system. Each troche contains about one grain (0.06 Gm.) of gambir, and the taste is not disagreeable.

TROCHISCI GLYCYRRHIZÆ ET OPII. U. S.

TROCHES OF GLYCYRRHIZA AND OPIUM

(trɔ-phis'cī glŷc-ŷr-rhī'zæ èt ɔ'pī-i)

Licorice and Opium Lozenges; Tablettes d'Opium, Tablettes de Régilisse opiacées, *Fr.*; Opiumpastillen, *G.*

* "Extract of Glycyrrhiza, in fine powder, fifteen grammes [or 231 grains]; Powdered Opium, one-half gramme [or 8 grains]; Acacia, in fine powder, twelve grammes [or 185 grains]; Sugar, in fine powder, twenty grammes [or 309 grains]; Oil of Anise, two-tenths of a cubic centimeter [or 3 minims]; Water, a sufficient quantity, to make one hundred troches. Rub the powders together until they are thoroughly

mixed; then add the Oil of Anise (equivalent to about 4 drops), and incorporate it with the mixture. Lastly, with Water, form a mass, to be divided into *one hundred troches*." *U. S.*

The British Pharm. 1898 no longer recognizes lozenges containing licorice and opium; the Br. 1885 process is appended.¹

A preparation similar to the above is much used in Philadelphia and elsewhere under the name of *Wistar's cough lozenges*. Sometimes morphine sulphate is substituted in equivalent proportion for the opium, and occasionally a little tartar emetic is added; but these modifications of the official formula are not admissible without a change of title. Each *U. S.* troche contains about one-twelfth of a grain of powdered opium. These troches are demulcent and anodyne, and useful in allaying *cough*.

TROCHISCUS GUAIIACI RESINÆ. Br.

GUAIIACUM RESIN LOZENGE

(trq-ghis'cūs guai'q-cī rē-ſī'næ)

Tablettes de Résine de Gayac, *Fr.*; Guajakharzpastillen, *G.*

"Guaiacum Resin, 3 *grains* or 0.1944 gramme. Mix with the Fruit Basis to form a Lozenge." *Br.* (See p. 1298.)

TROCHISCUS IPECACUANHÆ. Br.

IPECACUANHA LOZENGE

(trq-ghis'cūs ip-q-cāc-ū-ān'hæ)

Tablettes d'Ipécacuanha, *Fr. Cod.*; Brechwurzelpastillen, *G.*; Pastiglie d'ipécacuanha, *It.*

"Ipecacuanha Root, in powder, $\frac{1}{2}$ *grain* or 0.0162 gramme. Mix with the Fruit Basis to form a Lozenge." *Br.* (See p. 1298.)

These are useful expectorant lozenges in *catarrhal complaints*.

TROCHISCI KRAMERIÆ. U. S. (Br.)

TROCHES OF KRAMERIA

(trq-ghis'cī krā-mē'ri-æ)

Trochiscus Krameria, *Br.*; *Krameria Lozenge*, *Rhatany Lozenge*; *Tablettes de Ratanhia*, *Fr.*; *Ratanhiapastillen*, *G.*

* "Extract of *Krameria*, six *grammes* [or 93 grains]; Sugar, in fine powder, *sixty-five gram-*

mes [or 2 ounces av., 128 grains]; *Tragacanth*, in fine powder, *two grammes* [or 31 grains]; *Stronger Orange Flower Water*, a *sufficient quantity*, to make *one hundred troches*. Rub the powders together until they are thoroughly mixed; then, with *Stronger Orange Flower Water*, form a mass, to be divided into *one hundred troches*." *U. S.*

"Extract of *Krameria*, 1 *grain* or 0.0648 gramme. Mix with the Fruit Basis to form a Lozenge." *Br.* (See p. 1298.)

These are astringent troches, which may be used in *chronic angina*.

TROCHISCUS KRAMERIÆ ET COCAINÆ. Br.

KRAMERIA AND COCAINE LOZENGE

(trq-ghis'cūs krā-mē'ri-æ èt cō-cā-ī'næ)

Tablettes de Ratanhia et de Cocaine, *Fr.*; *Ratanhia-und Cocain-pastillen*, *G.*

"Extract of *Krameria*, 1 *grain* or 0.0648 gramme; *Cocaine Hydrochloride*, one-twentieth *grain* or 0.00324 gramme. Mix with the Fruit Basis to form a Lozenge." *Br.* (See p. 1298.)

TROCHISCUS MORPHINÆ. Br.

MORPHINE LOZENGE

(trq-ghis'cūs mōr-phī'næ)

Tablettes de Chlorhydrate de Morphine, *Tablettes de Morphine*, *Fr.*; *Morphinpastillen*, *G.*

"Morphine Hydrochloride, one-thirty-sixth *grain* or 0.0018 gramme. Mix with the Tolu Basis to form a Lozenge." *Br.* (See p. 1298.)

Useful for alleviating *cough*, and for other purposes which are answered by minute doses of morphine, of the hydrochloride of which each lozenge contains about one-thirty-sixth of a grain (0.0018 Gm.).

TROCHISCUS MORPHINÆ ET IPECACUANHÆ. Br.

MORPHINE AND IPECACUANHA LOZENGE

(trq-ghis'cūs mōr-phī'næ èt ip-q-cāc-ū-ān'hæ)

Tablettes de Morphine et d'Ipécacuanha, *Fr.*; *Morphinpastillen mit Brechwurzel*; *Morphin- und Brechwurzel-pastillen*, *G.*

"Morphine Hydrochloride, one-thirty-sixth *grain* or 0.0018 gramme; *Ipecacuanha Root*, in powder, one-twelfth *grain* or 0.0054 gramme. Mix with the Tolu Basis to form a Lozenge." *Br.* (See p. 1298; also p. 790.)

Expectorant and anodyne, useful especially in *allaying cough*. The lozenges contain one-thirty-sixth of a grain (0.0018 Gm.) of morphine salt, and one-twelfth of a grain (0.0054 Gm.) of ipecacuanha.

¹ *Trochisci Opii*, *Br.* 1885. *Opium Lozenges*. "Take of Extract of Opium *seventy-two grains*; Tincture of Tolu *half a fluid ounce*; Refined Sugar, in powder, *sixteen ounces* [avoirdupois]; Gum Acacia, in powder, *two ounces* [av.]; Extract of Liquorice *six ounces* [av.]; Distilled Water a *sufficiency*. Add the Extract of Opium, first softened by means of a little Water, and the Tincture of Tolu, to the Extract of Liquorice heated in a water-bath. When the mixture is reduced to a proper consistence, remove it to a slab, add the Sugar and Gum previously rubbed together, and mix thoroughly. Divide the mass into 720 lozenges, and dry these in a hot-air chamber with a moderate heat. Each lozenge contains one-tenth of a grain of Extract of Opium, equivalent to one-fiftieth of a grain of morphine." *Br.* 1885.

TROCHISCI POTASSII CHLORATIS.

U. S. (Br.)

TROCHES OF POTASSIUM CHLORATE

(trō-ghis'ci pō-tās'si-i ēhlō-rā'tis)

Trochiscus Potassii Chloratis, *Br.*, Potassium Chlorate Lozenge, Chlorate of Potash Lozenges; Tablettes de Chlorate de Potasse, *Fr. Cod.*; Kalium-chloratpastillen, Pastillen von Chlorsaurem Kali, *G.*; Pastiglie di clorato di potassio, *It.*; Tabletás de clorato potásico, *Sp.*

* "Potassium Chlorate, in fine powder, fifteen grammes [or 231 grains]; Sugar, in fine powder, sixty grammes [or 2 ounces av., 51 grains]; Tragacanth, in fine powder, three grammes [or 46 grains]; Water, a sufficient quantity, to make one hundred troches. Mix the Sugar with the Tragacanth by trituration, in a mortar; then transfer the mixture to a sheet of paper, and by means of a bone spatula mix with it the Potassium Chlorate, being careful, by avoiding trituration or pressure, to prevent the mixture from igniting or exploding. Lastly, with Water, form a mass, to be divided into one hundred troches." *U. S.*

"Potassium Chlorate, 3 grains or 0.1944 gramme. Mix with the Rose Basis to form a Lozenge." *Br.* (See p. 1298.)

In the U. S. P. (8th Rev.) the size of these troches was reduced one-half as compared with those of the U. S. P. 1890.

These lozenges are very largely employed, and are locally useful in cases of sore throat.

TROCHISCI SANTONINI. U. S. (Br.)

TROCHES OF SANTONIN

(trō-ghis'ci sán-tō-ní'ni)

Trochiscus Santonini, *Br.*, Santonin Lozenge, *Br.*; Tablettes de Santonine, *Fr. Cod.*; Pastilli Santonini, *P. G.*; Santoninpastillen, *G.*; Pastiglie di santonina, *It.*; Tabletás de santonina, *Sp.*

* "Santonin, in fine powder, three grammes [or 46 grains]; Sugar, in fine powder, ninety grammes [or 3 ounces av., 76 grains]; Tragacanth, in fine powder, three grammes [or 46 grains]; Stronger Orange Flower Water, a sufficient quantity, to make one hundred troches. Rub the powders together until they are thoroughly mixed; then, with Stronger Orange Flower Water, form a mass, to be divided into one hundred troches. Troches of Santonin should be kept in dark, amber-colored vials." *U. S.*

"Santonin, 1 grain or 0.0648 gramme. Mix with the Simple Basis to form a Lozenge." *Br.* (See p. 1298.)

The United States process is faulty in the direction that the santonin should be in fine powder. The longer the absorption of santonin is delayed in the intestines the more prolonged and consequently the more effective is its vermifugal influence. As soon as it is absorbed it ceases to act upon the worm, and becomes a more or less deleterious substance in the system.

A dose of santonin in crystals which is not poisonous may become somewhat toxic when given in fine powder. The proportion of crystals in the lozenge mass ($2\frac{1}{2}$ per cent.) is not sufficient to prevent the formation of a good lozenge from a pharmaceutical point of view. Each U. S. lozenge contains about half a grain (0.033 Gm.) of santonin. (See *Santoninum*, p. 1085.)

Dose, for a child (two years old) from one to two lozenges.

TROCHISCI SODII BICARBONATIS.

U. S. (Br.)

TROCHES OF SODIUM BICARBONATE

(trō-ghis'ci só'di-i bí-cār-bō-nā'tis)

Trochiscus Sodii Bicarbonatis, Sodium Bicarbonate Lozenge, *Br.*; Trochisci Natri Bicarbonici; Tablettes de Bicarbonate de Soude, *Fr. Cod.*; Pastilles de Vichy, Pastilles digestives, *Fr.*; Natronpastillen, Natriumbicarbonatpastillen, *G.*; Pastiglie di bicarbonato di sodio, *It.*; Tabletás de bicarbonato sódico, *Sp.*

* "Sodium Bicarbonate, eighteen grammes [or 278 grains]; Sugar, in fine powder, fifty-four grammes [or 1 ounce av., 396 grains]; Myristica, bruised, one gramme [or 15 grains]; Mucilage of Tragacanth, a sufficient quantity, to make one hundred troches. Triturate the Myristica with the Sugar, gradually added, until they are reduced to a fine powder, and mix this intimately with the Sodium Bicarbonate; then, with the Mucilage of Tragacanth, form a mass, to be divided into one hundred troches." *U. S.*

"Sodium Bicarbonate, 3 grains or 0.1944 gramme. Mix with the Rose Basis to form a Lozenge." *Br.* (See p. 1298.)

The U. S. troche contains about three grains (0.18 Gm.) of the alkaline salt. Antacid and antilithic, useful in heartburn and in uric acid gravel. From one to six may be given for a dose.

TROCHISCUS SULPHURIS. *Br.*

SULPHUR LOZENGE

(trō-ghis'cūs sūl'phū-ris)

Tablettes de Soufre, *Fr. Cod.*; Schwefelpastillen, *G.*

"Precipitated Sulphur, 2500 grains or 162 grammes; Acid Potassium Tartrate, in powder, 500 grains or 32.4 grammes; Refined Sugar, in powder, 4000 grains or 259.2 grammes; Gum Acacia, in powder, 500 grains or 32.4 grammes; Tincture of Orange, 500 minims or 29.5 cubic centimetres; Mucilage of Gum Acacia, 500 minims or 29.5 cubic centimetres. Mix the Tincture of Orange with the powders; add the Mucilage of Gum Acacia to form a suitable mass. Divide into five hundred Lozenges. Dry them in a hot-air chamber at a moderate temperature. Each Lozenge contains five grains or 0.324 gramme of Precipitated Sulphur." *Br.*

These lozenges were first introduced into the "Additions" to the British Pharmacopœia 1885.

Dose, from one to six lozenges. (See *Sulphur Præcipitatum*, p. 1202.)

ULMUS. U. S.

ELM [Slippery Elm]

(ûl'mûs)

"The dried bark of *Ulmus fulva* Michaux (Fam. *Ulmaceæ*), deprived of its periderm." *U. S.*

Cortex Ulmi Interior, Ulmi Cortex; Elm Bark; Orme Fauve, *Fr. Cod.*; Ecorce d'Orme, *Fr.*; Ulmenrinde, *Rüsterlinde, G.*

Ulmus fulva, Michaux, *Flor. Bor. Amer.* (1803), i. 172.—*U. rubra*, Michx. f., *Hist. Arb. Am.*, iii. 278.—*U. pubescens*, Walt., *Fl. Car.* (1788), 112.—The slippery elm, called also red elm, is a lofty tree, fifty or sixty feet in height, with a trunk fifteen or twenty inches in diameter. The bark of the trunk is brown, that of the branches rough and whitish. The leaves are oblong-ovate, acuminate, nearly equal at the base, unequally serrate, pubescent, and very rough on both sides, four or five inches in length by two or three in breadth, and supported on short footstalks. The buds, a fortnight before their development, are covered with a dense russet down. The flowers, which appear before the leaves, are sessile, and in clusters at the extremities of the young shoots. The bunches of flowers are surrounded by scales, which are downy like the buds. The calyx is also downy. There is no corolla. The stamens are five, short, and of a pale rose color. The fruit is a membranaceous capsule or samara, enclosing in the middle one round seed, destitute of fringe.¹ The family *Urticaceæ* has been subdivided by Engler and Prantl into three distinct natural orders: 1, the *Ulmaceæ*, including *Ulmus*, etc.; 2, the *Moraceæ*, including *Morus*, *Humulus*, *Cannabis*, etc.; 3, the *Urticaceæ* proper, including *Urtica*, etc.

This species of elm is indigenous, growing in all parts of the United States north of the Carolinas, but most abundantly west of the Alleghany Mountains. It flourishes in open, elevated situations, and requires a firm, dry soil. From the white elm (*U. americana*) it is distinguished by its rough branches, its larger, thicker, and rougher leaves, its downy buds, and the character of its flowers and seeds. Its period of flowering is in April. The inner bark, separated from the cortex, is the part used. Large quantities are collected in the Lower Peninsula of Michigan.

It is in long, nearly flat pieces, from one to two lines thick, of a fibrous texture, a tawny

color which is reddish on the inner surface, a peculiar sweetish, not unpleasant odor, and a highly mucilaginous taste when chewed. "In flat pieces varying in length and width, 3 to 4 Mm. thick; outer surface light brown, with occasional dark brown patches of the periderm; inner surface yellowish-brown; fracture fibrous and somewhat mealy; odor slight but distinct; taste mucilaginous. Ground Elm contains a few nearly spherical starch grains from 0.005 to 0.010 Mm. in diameter." *U. S.* By grinding, it is reduced to a light, grayish fawn-colored powder. It abounds in mucilaginous matter, which it readily imparts to water. The mucilage is precipitated by solutions of lead acetate and subacetate, but not by alcohol. It contains a variety of tannin which colors iron solutions green, in amount about 6.5 per cent. according to Rink, or, according to Davy, a little less than 3 per cent.

Much of the bark brought into the market is of inferior quality, imparting comparatively little mucilage to water. It has the characteristic odor of the genuine bark, but is much less fibrous and more brittle, breaking abruptly when bent, instead of being capable, like the better kinds, of being folded lengthwise without breaking. To what this inferiority is owing, whether to difference in the species or the age, or to circumstances in the growth of the tree producing it, we are unable to state. Ground elm bark is often adulterated, usually with substances containing starch. Pure elm bark contains only a trace of starch.²

C. W. Wright of Cincinnati, in a communication to the *Western Lancet*, states that slippery elm bark has the property of preserving fatty substances from rancidity, and that this fact was known to the Indians, who prepared bear's fat by melting it with the bark, in the proportion of a drachm of the latter to a pound of the former, keeping them heated together for a few minutes, and then straining off the fat. Wright tried the same process with butter and lard, and found them to remain perfectly sweet for a long time. (*A. J. P.*, xxiv.)

Uses.—Elm bark is an excellent demulcent, applicable to all cases in which this class of medicines is employed. It is especially recommended in *dysentery*, *diarrhœa*, and *diseases of the urinary passages*. Its mucilage is nutritious, and we are told that it has proved sufficient for the support of life in the absence of other food. In the case of a lad of fifteen, elm bark produced death, which was due to the effects of the numerous balls of indigestible fibre which were formed in the stomach. (*P. M. T.*, Feb. 7, 1874, p. 303.)

J. R. Dowler of Beardstown, Ill., reports the discharge of *tape worm* caused by chewing and

¹ *Fremontia californica*, Torr., or *California Slippery Elm*, is not botanically allied to *Ulmus fulva*; its bark is said, however, to have the same properties as slippery elm bark, and to be used for a similar purpose.

² The following test, devised by Geo. M. Berlinger, seems to have practical value. Ten grains of ground or pulverized elm bark, thoroughly shaken with one fluidounce of water, will, if pure and of good quality, in fifteen minutes form a thick jelly-like mass of a good fawn color.

swallowing the bark of the elm. (*B. M. S. J.*, March 16, 1865, p. 132.) It is commonly used as a drink in the form of infusion. (See *Mucilago Ulmi*.) The powder may be used stirred in hot water, with which it forms a mucilage more or less thick according to the proportion added. The bark also serves as an emollient application in cases of *external inflammation*. For this purpose the powder may be formed into a poultice with hot water, or the bark itself may be applied, previously softened by boiling. McDowell of Virginia, recommended slippery elm bark for the dilatation of *fstulas* and *strictures* (*Med. Examiner*, i. 244); subsequently H. R. Storer of Boston, used it advantageously for *dilating the os uteri* (*B. M. S. J.*, liii. 300), and A. Abbe of the same place, succeeded in curing with it a case of *stricture of the rectum* (*Ibid.*, liv. 349).

Off. Prep.—Mucilago Ulmi, *U. S.*

UNGUENTA.

OINTMENTS

(*un-guën'tä*)

Pommades, Onguents, *Fr.*; Salben, *G.*; Pomatas, Unguentos, *It.*; Pomadas, Unguentos, *Sp.*

These are fatty substances, softer than cerates, of a consistence like that of butter, and such that they may be readily applied to the skin by inunction. When ointments are prepared by merely mixing medicinal substances with *simple ointment*, *hydrous wool-fat*, *lard*, or *petrolatum*, care should be taken, if the added substance be a powder, that it be brought to the finest possible state of division before being incorporated with the unctuous matter. If soluble in water or in alcohol, it may often be advantageously rubbed with a little of one of these liquids. Gritty matter should not be allowed to enter these preparations. When an extract is added, if not uniformly soft, it should be made so by trituration with water or alcohol, according to its nature. Many of the ointments become rancid if long kept, and should, therefore, be prepared in small quantities at a time, or only when wanted for use. The tendency to rancidity may be in a considerable degree counteracted by imbuing the unctuous vehicle with benzoin, or with poplar buds, as recommended by Deschamps (*A. J. P.*, xv. 260); but care should be taken that there be no therapeutic objection to the admixture.¹ Elm

bark is said to have the same effect. (See p. 1303.) According to Geisler, ten drops of spirit of nitrous ether, incorporated with an ounce of ointment, will overcome the disagreeable fatty odor. (*Ph. Cb.*, 1847, 927.) Hydrous wool-fat or lanolin, petrolatum, and glycerite of starch are now used as vehicles for ointments. (See *Adeps Lanae Hydrosus*, *Petrolatum*, and *Glyceritum Amyli*.) In the selection of a vehicle for an ointment it is important to consider the object for which the ointment is to be used. Lanolin is a natural emollient of the skin, composed of cholesterin and other substances.

Glycelæum is an oleaginous compound of finely powdered almond meal 1 part, glycerin 2 parts, and olive oil 6 parts. It was proposed by T. B. Groves, *C. D.*, Sept. 14, 1867, as a substitute for plasma and other fatty bodies, and has no doubt advantages, one of which is the facility with which it can be removed from the skin by a wet sponge. It has been proposed to substitute glycerin for oils and fats in the preparation of ointments, either wholly or in part; but ointments thus prepared are altogether unfit for application by inunction, as a portion of the glycerin remains upon the skin, producing a rough sensation of adhesiveness, very different from the softness caused by oleaginous matter, and in some skin diseases glycerin in an ointment would be positively injurious.

The Cerates having been abolished as a class in the British Pharmacopœia, a few of the individual articles have been transferred to the Ointments, making the definition of the latter class of preparations, as given above, not exactly applicable to all the individual substances at present included among them in that Pharmacopœia. We consider no substance to be strictly entitled to the name of ointment which is not of such a consistence as to adapt it to application to the skin by friction or inunction. Ointments should be dispensed in glass, porcelain, or queensware pots or jars, or, if for temporary use, in tight wooden boxes. We have used a very convenient method of dispensing soft ointments by introducing them into compressible tubes. These tubes are similar to those used for holding artists' colors, and have the advantage of shielding the ointment from the oxidizing action of the air while allowing the use of the desired quantity. In the *U. S. P.* (8th Rev.) the following new ointments were introduced: Unguentum Acidi Borici, Hydrargyri Dilutum, Zinci Stearatis. Unguentum Stramonii is made from the extract of the leaf instead of that from the seed. The following ointments of the *U. S.* 1890 were not admitted: Unguentum Plumbi Carbonatis, Plumbi Iodidi.¹ For a classifica-

¹ *Populinated Lard*.—Emile Mouchon gives the following method of applying to lard the preservative influence of poplar buds and benzoin. Having prepared, by percolation, a *tincture of poplar buds* from one part of the dried buds in powder and four parts of alcohol, he adds by degrees to 1000 parts of melted lard 60 parts of the tincture, heats so that all the alcohol may be driven off, then strains, and agitates the mixture till it concretes on cooling. The same method is pursued with tincture of benzoin, in the same proportions; and tincture of gualac will answer the same purpose. Lard thus prepared keeps perfectly well for a very long time. (*J. P. O.*, xxv. 458.) T. B. Groves has shown that oil of pimenta and balsam of Peru have in a powerful degree the same preservative influence on lard. (*P. J.*, Nov. 1864, p. 240.)

¹ *Unguentum Plumbi Carbonatis*. *U. S.* 1890. Ointment of Lead Carbonate.—Lead Carbonate, in very fine powder, ten grammes [or 154 grains]; Benzoinated Lard, ninety grammes [or 3 ounces av., 76 grains]; to make one hundred grammes [or 3 ounces av., 281 grains]. Rub the Lead Carbonate with the

tion of ointments in accordance with their therapeutic use by C. S. N. Hallberg, see *West. Drug.*, 1900, 652.

UNGUENTUM. U. S.

OINTMENT

(un-guën'tüm)

Unguentum Adipis, *U. S.* 1860; Unguentum Simplex; Simple Ointment; Pommade simple, *Fr.*; Unguentum cereum, *P. G.*; Wachssalbe, *G.*

* "White Wax, two hundred grammes [or 7 ounces av., 24 grains]; Benzoinated Lard, eight hundred grammes [or 28 ounces av., 96 grains], to make one thousand grammes [or 35 ounces av., 120 grains]. Melt the White Wax, add the Benzoinated Lard, and heat gently until liquefied; then stir the mixture until it congeals." *U. S.*

Yellow wax was used in this ointment in the *U. S. P.* 1890 and objection was made to the color of the ointment. It has been very properly replaced by white wax in the *U. S. P.* (8th Rev.) and the lard is now benzoinated.

This is emollient, and is occasionally employed as a mild dressing to blistered or excoriated surfaces, but more frequently as a vehicle, it being the basis of several official ointments.¹

Off. Prep.—Unguentum Acidi Tannici, *U. S.*; Unguentum Gallæ, *U. S.*

UNGUENTUM ACIDI BORICI. U. S., Br.

BORIC ACID OINTMENT

(un-guën'tüm äç'i-dī bō'rī-cl)

Pommade de l'Acide Borique, *Fr.*; Unguentum Acidī Borici, *P. G.*; Borsalbe, *G.*

* "Boric Acid, in fine powder, one hundred grammes [or 3 ounces av., 231 grains]; Paraffin, one hundred grammes [or 3 ounces av., 231 grains]; White Petrolatum, eight hundred grammes [or 28 ounces av., 96 grains], to make one thousand grammes [or 35 ounces av., 120 grains]. Melt the Paraffin, add the White Petrolatum, and heat gently for ten minutes. Then gradually add the hot liquid to the Boric Acid, contained in a warm mortar, triturating thoroughly, and stir the mixture until it congeals." *U. S.*

Benzoinated Lard, gradually added, until they are thoroughly mixed." *U. S.* 1890.

This ointment is used as a dressing to blistered or excoriated surfaces, burns, etc.

Unguentum Plumbi Iodidi, *U. S.* 1890. Ointment of Lead Iodide.—"Lead Iodide, in very fine powder, ten grammes [or 154 grains]; Benzoinated Lard, ninety grammes [or 3 ounces av., 76 grains], to make one hundred grammes [or 3 ounces av., 231 grains]. Rub the Lead Iodide with the Benzoinated Lard, gradually added, until they are thoroughly mixed." *U. S.* 1890.

For the uses of this ointment, see *Plumbi Iodidum*.
¹ Unguentum Simplex, *Br.* 1885. Simple Ointment. "Take of White Wax two ounces [avoirdupois]; Benzoinated Lard three ounces [av.]; Almond Oil three fluid ounces. Melt the Wax and Lard in the Oil on a water-bath; then remove the mixture, and stir constantly while it cools." *Br.* 1885. (See also *U. S.* 1850.)

"Boric Acid, in very fine powder, carefully sifted, 1 ounce (Imperial) or 30 grammes; Paraffin Ointment, white, 9 ounces (Imp.) or 270 grammes. Mix." *Br.*

This ointment was introduced into the *U. S. P.* (8th Rev.); it closely resembles the British ointment.

UNGUENTUM ACIDI SALICYLICI. Br.

SALICYLIC ACID OINTMENT

(un-guën'tüm äç'i-dī sāl-i-cyl'i-cl)

Pommade d'Acide Salicylique, *Fr.*; Salicylsalbe, *G.*

"Salicylic Acid, in powder, 10 grains or 0.5 gramme; Paraffin Ointment, white, 490 grains or 24.5 grammes. Mix." *Br.*

UNGUENTUM ACIDI TANNICI. U. S.

OINTMENT OF TANNIC ACID

(un-guën'tüm äç'i-dī tăn'nī-cl)

Pommade d'Acide tannique, Pommade de Tannin, *Fr.*; Tanninsalbe, *G.*

* "Tannic Acid, twenty grammes [or 309 grains]; Glycerin, twenty grammes [or 309 grains]; Ointment, sixty grammes [or 2 ounces av., 51 grains], to make one hundred grammes [or 3 ounces av., 231 grains]. Dissolve the Tannic Acid in the Glycerin, with the aid of a gentle heat, and mix the solution thoroughly with the Ointment in a mortar, avoiding the use of iron utensils." *U. S.*

Ointment of Tannic Acid was doubled in strength at the *U. S. P.* 1890 revision. It is an excellent application in many cases of piles and prolapsus ani, also for flabby ulcers.

UNGUENTUM ACONITINÆ. Br.

ACONITINE OINTMENT

(un-guën'tüm æc-ōn-i-tī-næ)

Pommade d'Oleate d'Aconitine, Pommade d'Aconitine, *Fr.*; Aconitinoleatsalbe, Aconitinsalbe, *G.*

"Aconitine, 10 grains or 0.5 gramme; Oleic Acid, 80 grains or 4 grammes; Lard, 410 grains or 20.5 grammes. Rub the Aconitine with the Oleic Acid, and gently warm the mixture until dissolved; add the Lard; mix." *Br.*

For the uses of this preparation the reader is referred to the articles on *Aconitum* and *Aconitina*. Care must be taken not to apply it to an abraded or ulcerated surface, lest it produce serious constitutional effects.

UNGUENTUM AQUÆ ROSÆ. U. S., Br.

OINTMENT OF ROSE WATER

(un-guën'tüm ä'quæ rō'sæ)

Rose Water Ointment; Unguentum Emolliens; Cold-cream, *Fr. Cod.*; Crème cosmétique, Crème froide, *Fr.*; Unguentum leniens, *P. G.*; Cold Cream, *G.*

* "Spermaceti, one hundred and twenty-five grammes [or 4 ounces av., 179 grains]; White

Wax, *one hundred and twenty grammes* [or 4 ounces av., 102 grains]; Expressed Oil of Almond, *five hundred and sixty grammes* [or 19 ounces av., 330 grains]; Sodium Borate, in fine powder, *five grammes* [or 77 grains]; Stronger Rose Water, *one hundred and ninety grammes* [or 6 ounces av., 307 grains]; to make about *one thousand grammes* [or 35 ounces av., 120 grains]. Reduce the Spermaceti and the White Wax to fine shavings and melt them at a moderate heat, add the Expressed Oil of Almond and stir, continuing the heat until the mixture is uniform; then gradually add the Stronger Rose Water, previously warmed, and in which the Sodium Borate has been dissolved, stirring the mixture rapidly and continuously until it congeals and becomes of uniform consistence. When this Ointment is to be used as a vehicle for metallic salts, the Sodium Borate should be omitted." *U. S.*

"Rose Water, undiluted, 7 fl. ounces (Imp. meas.) or 210 cubic centimetres; White Beeswax, 1½ ounces (Imp.) or 45 grammes; Spermaceti, 1½ ounces (Imp.) or 45 grammes; Almond Oil, 9 ounces (Imp.) or 270 grammes; Oil of Rose, 8 minims or 0.5 cubic centimetre. Melt together the White Beeswax, Spermaceti, and Almond Oil; pour the mixture into a warmed mortar and add the Rose Water gradually with constant trituration; add the Oil of Rose; continue the trituration until cold." *Br.*

In the U. S. P. 1890 process the proportion of rose water was greatly reduced,—i.e., from 30 to 20 per cent.; this makes a more stable preparation, but in our opinion the usefulness of the ointment has been curtailed by the reduction, its soft consistence being one of its most valuable characteristics. Sodium borate was added to increase its whiteness; its presence may, however, prove objectionable when the ointment is used as a basis in prescriptions, by reacting with some of the ingredients ordered by the physician. The 1890 formula was retained with but slight changes in the U. S. P. (8th Rev.). The manipulation was somewhat modified to increase uniformity of the product.

This preparation is a white, very soft, and elegant ointment, deriving a grateful odor from the rose water, which remains incorporated with the other constituents if kept enclosed in glazed vessels. We have found it an improvement to add oil of rose in the proportion of one drop to eight ounces, and to use an instrument known as the "Dover egg-beater" for giving it the desired creamy appearance. It is a pleasant, cooling application to irritated and excoriated surfaces, and may be used with great advantage for *chapped lips and hands*, so frequent in cold weather. Cold cream is not recognized in the U. S. Pharmacopœia (8th Rev.) as an official synonym for ointment of rose water. This course became necessary because of the large number of unofficial ointments of varying composition popularly exploited as cold creams, and these were frequently dis-

pensed, when physicians' prescriptions directed Ointment of Rose Water. The commercial cold creams must be made from substances which are not liable to rancidity, and paraffin oil, liquid petrolatum, white petrolatum, etc., largely form the basis of such, but the official ointment is to be preferred for use in prescriptions. W. C. Alpers furnishes the following formula for a cold cream which is more permanent than the official ointment. 150 parts of white wax is melted in 600 parts of paraffin oil with the aid of a gentle heat; 9 parts of borax is dissolved in 240 parts of water; the two fluids are brought to a uniform temperature, not exceeding 60° C., and the aqueous solution is poured into the oily one in a continuous stream, stirring gently for a minute or two; then 1 part of oil of geranium and a little oil of rose are added while stirring, and the product while still warm is poured into jars. The cold cream so obtained is white, soft and smooth, pleasantly odorous, keeps well in the heat of summer and the cold of winter, and becomes only slightly thinner in summer. As the ointment is liable to become rancid when long kept, and the water to separate upon exposure, Joseph Laidley has proposed the substitution for the rose water of oil of rose and glycerin, the former in the proportion of two drops, the latter in that of four fluidrachms, the quantity of spermaceti being increased by two drachms. (*A. J. P.*, xii. 119.) For some purposes the substitution is useful, but the official preparation is preferable for *chapped hands*, as the glycerin frequently leaves an unpleasant sensation of stickiness on the skin.

UNGUENTUM ATROPINÆ. *Br.*

ATROPINE OINTMENT

(*un-guën'tüm ät-rō-pī'næ*)

Pommade d'Oleate d'Atropine, Pommade d'Atropine, *Fr.*; Atropinoleatsalbe, Atropinsalbe, *G.*

"Atropine, 10 grains or 0.5 gramme; Oleic Acid, 40 grains or 2 grammes; Lard, 450 grains or 22.5 grammes. Rub the Atropine with the Oleic Acid, and gently warm the mixture until dissolved; add the Lard; mix." *Br.*

For the uses of this ointment, see *Belladonna* and *Atropina*, p. 215, also p. 821. Caution must be observed that the ointment shall not come in contact with abraded, ulcerated, or wounded surfaces, and that it be not applied too freely to sound skin.

UNGUENTUM BELLADONNÆ.

U. S., Br.

BELLADONNA OINTMENT

(*un-guën'tüm bēl-lā-dōn'næ*)

Pommade Belladonné, *Fr. Cod.*; Pommade de Belladone, *Fr.*; Belladonnasalbe, Tollkirschensalbe, *G.*

* "Extract of Belladonna Leaves, ten grammes [or 154 grains]; Diluted Alcohol, five cubic

centimeters [or 81 minims]; Hydrous Wool-Fat, *twenty grammes* [or 309 grains]; Benzoinated Lard, *sixty-five grammes* [or 2 ounces av., 128 minims], to make about *one hundred grammes* [or 3 ounces av., 231 grains]. Triturate the Extract with the Diluted Alcohol until a smooth mixture is obtained; with this incorporate the Hydrous Wool-Fat; then add the Benzoinated Lard and mix thoroughly." *U. S.*

"Liquid Extract of Belladonna, 2 *fl. ounces* (Imperial measure) or 40 cubic centimetres; Benzoated Lard, 2½ *ounces* (Imp.) or 45 grammes. Evaporate the Liquid Extract of Belladonna on a water-bath until it is reduced to a *quarter of an ounce* (Imp.) or five grammes; add the Benzoated Lard; mix. 100 parts of this Ointment should contain 0.6 part of the alkaloids of Belladonna Root." *Br.*

This is a convenient form for the external application of extract of belladonna. Care must be taken in preparing it that the extract employed have the due consistence, and, if dry and lumpy, it may be restored to the proper state by rubbing it with a little water in a heated mortar. The use of diluted alcohol, as now officially directed, is still better.

UNGUENTUM CANTHARIDIS. Br.

CANTHARIDES OINTMENT

(*un-guën'tüm càn-thâr'î-dis*)

Unguentum Irritans, Unguentum ad Fonticulos; Pomme Epispastique (jaune, verte), *Fr. Cod.*; Onguent de Cantharides, *Fr.*; Unguentum Cantharidum, *P. G.*; Spanischfliegensalbe, *G.*; Unguento de cantaridas, *Sp.*

"Cantharides, bruised, 1 *ounce* (Imperial) or 30 grammes; Benzoated Lard, 10 *ounces* (Imp.) or 300 grammes. Melt the Benzoated Lard, add the Cantharides, and digest at a temperature of about 120° F. (48.9° C.) for twelve hours. Strain through calico and press the residue gently; stir until cold." *Br.*

The British (1885) process was a better one than that of the U. S. Pharm. 1870.¹ Olive oil is a good solvent of cantharidin. By its use the active matter of the flies is more uniformly diffused through the ointment than when they are directly incorporated in the state of powder, with the other ingredients. The preparation is thus better calculated to meet the end proposed of maintaining the discharge from blistered surfaces without producing undue irritation. It has been said that the virtues of the flies are impaired by boiling, but the contrary has been proved to be the case, the cantharidin being neither altered nor volatilized at 100° C. (212° F.). (See *Cantharis*.) Benzoated lard as directed in the Br. (1898) process, even when kept at a temperature of 120° F. during digestion, is not as effective as olive oil as a solvent for cantharidin.

It should be recollected that this ointment is intended as a dressing for blisters, not to produce vesication. The Committee of Revision wisely omitted the preparation from the U. S. P. 1880, as it was frequently prescribed under the impression that it was equal in strength to the cerate, in fact, identical with it, and disappointment resulted. Such a preparation should be left to extemporaneous prescription. *Dupuytren's ointment*, employed as a local application to prevent the loss of hair, was made by macerating a drachm of flies in a fluidounce of alcohol, and incorporating one part of the tincture thus formed with nine parts of lard.

UNGUENTUM CAPSICI. Br.

CAPSICUM OINTMENT

(*un-guën'tüm cäp'si-cî*)

Pommade de Piment des Jardins, *Fr.*; Spanisch-Pfeffersalbe, *G.*

"Capsicum Fruit, bruised, 120 *grains* or 12 grammes; Spermaceti, 60 *grains* or 6 grammes; Olive Oil, 1 *ounce* (Imperial) or 44 grammes. Digest on a water-bath for one hour, occasionally stirring; strain; set aside to cool, without stirring." *Br.*

UNGUENTUM CETACEI. Br.

SPERMACETI OINTMENT

(*un-guën'tüm cë-tä'cë-i*)

Pommade de baleine, *Fr.*; Walrathsalbe, *G.*

"Spermaceti, 20 *ounces* (Imperial) or 200 grammes; White Beeswax, 8 *ounces* (Imp.) or 80 grammes; Almond Oil, 72 *ounces* (Imp.) or 720 grammes; Benzoin, in coarse powder, 2 *ounces* (Imp.) or 20 grammes. Melt together the Spermaceti, Beeswax, and Almond Oil; add the Benzoin, and, frequently stirring the mixture, continue the application of heat for two hours; remove from the source of heat; strain; and stir the Ointment constantly until cold." *Br.*

Spermaceti cerate (U. S. P. 1890) was not admitted to the U. S. P. (8th Rev.).¹

¹ *Ceratum Cetacei*. U. S. 1890. *Spermaceti Cerate*. "Spermaceti, one hundred grammes [or 3 ounces av., 230 grains]; White Wax, three hundred and fifty grammes [or 12 ounces av., 151 grains]; Olive Oil, five hundred and fifty grammes [or 19 ounces av., 175 grains], to make one thousand grammes [or 35 ounces av., 120 grains]. Melt together the Spermaceti and White Wax; then add the Olive Oil previously heated, and stir the mixture constantly until it is cool." U. S. 1890.

The direction to heat the oil before adding it to the other ingredients is important. If added cold, it is apt to produce an irregular congelation of the wax and spermaceti, and thus to render the preparation lumpy. The cerate is employed as a dressing for blisters, excoriated surfaces, and wounds, and as the basis of more active preparations. When the ingredients are pure and sweet, it is perfectly free from irritating properties. The above formula contains a little less spermaceti than that of the U. S. P. 1870. From experiments made by J. B. Barnes, it appears that this cerate keeps much better when made of unbleached materials than when prepared with olive oil and wax previously bleached. (*P. J.* 1861, p. 352.)

¹ "Take of Cantharides Cerate one hundred and twenty grains; Resin Cerate three hundred and sixty grains. Mix them thoroughly." U. S. 1870.

This ointment is employed as a mild dressing for blisters, wounds, and excoriated surfaces. It should be made in small quantities at a time, as it is apt to become rancid when long kept.

UNGUENTUM CHRYSAROBINI.

U. S., Br.

CHRYSAROBIN OINTMENT

(ṽn-guēn'tūm chrys-ā-rō-bī'ni)

Pommade de Chrysarobine, Pommade de Poudre de Goa, Fr.; Chrysarobinsalbe, Goapulversalbe, G.

* "Chrysarobin, *six grammes* [or 93 grains]; Benzoated Lard, *ninety-four grammes* [or 3 ounces av., 138 grains], to make about *one hundred grammes* [or 3 ounces av., 231 grains]. Triturate the Chrysarobin with the Benzoated Lard, previously melted, and heat the mixture on a water-bath with occasional stirring for twenty minutes; then strain and stir until it congeals." U. S.

"Chrysarobin, 20 grains or 2 grammes; Benzoated Lard, 480 grains or 48 grammes. Triturate the Chrysarobin gradually with the Benzoated Lard, previously melted by heat; continue the heat until the Chrysarobin is dissolved; stir until cold." Br.

This ointment was reduced one-half in strength at the U. S. P. 1890 revision, but was slightly increased in strength in the Eighth Revision; it is now about one-third stronger than the British ointment. It was formerly used in *psoriasis, ringworm*, and other diseases of the skin, but its use has been to a great extent abandoned, on account of the permanent stain it leaves upon the linen.¹ It is preferably made by dissolving the chrysarobin in a little hot benzene, mixing this rapidly with a portion of the melted lard, and subsequently stirring before adding the rest of the lard.

UNGUENTUM COCAINÆ. Br.

COCAINE OINTMENT

(ṽn-guēn'tūm cō-cā-ī'næ)

Pommade d'Oléate de Cocaine, Fr.; Cocainoleatsalbe, G.

"Cocaine, 20 grains or 1 gramme; Oleic Acid, 80 grains or 4 grammes; Lard, 400 grains or 20 grammes. Rub the Cocaine with the Oleic Acid, and gently warm the mixture until dissolved; add the Lard; mix." Br.

UNGUENTUM CONII. Br.

CONIUM OINTMENT

(ṽn-guēn'tūm cō-nī'i)

Pommade de Grand Ciguë, Fr.; Schirlingsalbe, G.

"Juice of Conium, 2 fl. ounces (Imperial measure) or 88 cubic centimetres; Hydrous Wool Fat, $\frac{1}{2}$ ounce (Imp.) or 33 grammes. Evaporate the Juice of Conium on a water-bath to one eighth of its volume, at a temperature not exceeding 140° F. (60° C.); add the Hydrous Wool Fat; mix by trituration." Br.

It may be applied locally to cancerous or other painful ulcers, but has little therapeutic value.

UNGUENTUM CREOSOTI. Br.

CREOSOTE OINTMENT.

(ṽn-guēn'tūm crē-ō-sō'ti)

Pommade Créosotée, Pommade de Créosote, Fr.; Kreosotsalbe, G.

"Creosote, 1 ounce (Imperial) or 30 grammes; Hard Paraffin, 4 ounces (Imp.) or 120 grammes; Soft Paraffin, white, 5 ounces (Imp.) or 150 grammes. Melt the Hard and Soft Paraffins together; add the Creosote; stir until cold." Br.

The British ointment is more than twice as strong as that official in the U. S. P. 1870, which was made by mixing half a fluidrachm of creosote with a troyounce of lard. For the use of this ointment, see *Creosotum*. It may sometimes be advantageously diluted with lard when found to irritate.

UNGUENTUM DIACHYLON. U. S.

DIACHYLON OINTMENT

(ṽn-guēn'tūm dī-āch'ylōn)

Unguentum Plumbi Hebræ; Hebra's Lead Ointment; Onguent Diachylon, Pommade de Diachylon, Fr.; Unguentum diachylon, P. G.; Bleipfastersalbe, Diachylonsalbe, G.

* "Lead Plaster, *fifty grammes* [or 1 ounce av., 334 grains]; Oil of Lavender Flowers, *one gramme* [or 15 grains]; Olive Oil, *forty-nine grammes* [or 1 ounce av., 319 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Melt the Lead Plaster by applying a gentle heat, add the Olive Oil, and mix thoroughly; then allow the mixture to cool, add the Oil of Lavender Flowers, and stir the ointment until it congeals. It should be prepared extemporaneously." U. S.

This ointment has been largely used by dermatologists in *eczema* and other skin diseases. It is frequently called "*Unguentum Diachylon Hebræ*," on account of its extensive use by Hebra of Vienna. Vulpinus states that the ointment used at Hebra's clinic, made according to the following formula, is very superior and will keep for weeks. Twenty parts of litharge are heated with sufficient water and eighty parts of olive oil until the reaction is completed, when one part of oil of lavender is added to the strained and cooling mass.

Our experience with the ointment made by the latter formula is that the tendency to rancidity constitutes its greatest objection, and

¹ The ointment of pyrogallie acid, of the strength of from ten to forty grains to the ounce, has been used to some extent as a substitute for chrysarobin ointment. It is slower in its action than the ointment of chrysarobin, and also stains the hair, skin, etc. It is said when used too freely to cause constitutional disturbance, with fever, greenish urine, etc.

in warm weather it is impossible to keep it longer than a few days. If even slightly rancid, it is unfit for use in most cases. A. Deringer (*Ph. Z. R.*, 1880, p. 103; *A. J. P.*, Sept. 1880) recommended the following modification. Dissolve 200 grammes of lead acetate in 1 liter of distilled water and 300 grammes of white Marseilles soap in $1\frac{1}{2}$ liters of distilled warm water, filter both solutions, mix, wash the resulting precipitate frequently with distilled water, and, after removing the moisture from it as much as possible, melt 1 part of it together with $1\frac{1}{2}$ parts of the best olive oil with a steam evaporating apparatus, and triturate into a white, smooth ointment in a mortar, which then possesses all the excellent mild and healing properties of Hebra's ointment. See *Emplastrum Plumbi*, page 441.

Eisner's modification, approved by L. A. Duhring, is as follows. One part of freshly precipitated (from lead acetate) pure white lead hydroxide is rubbed with two parts of water, and mixed well with six parts of the best Lucca olive oil. It should be stirred for about two hours over a hot water bath, and cooled with constant stirring until the proper consistence is obtained. While cooling, a drachm of oil of lavender is to be added to each half-pound of ointment. (*M. T. G.*, May 7, 1881.)

UNGUENTUM EUCALYPTI. Br.

EUCALYPTUS OINTMENT

(*un-guën'tüm eü-ca-lyp'ti*)

Pommade d'Eucalypte, *Fr.*; Eukalyptussalbe, *G.*

"Oil of Eucalyptus, 1 ounce (Imperial) or 30 grammes; Hard Paraffin, 4 ounces (Imp.) or 120 grammes; Soft Paraffin, white, 5 ounces (Imp.) or 150 grammes. Melt the Hard and Soft Paraffins together; add the Oil of Eucalyptus; stir until cold." *Br.*

This ointment is used as a stimulant to indolent ulcers and in skin diseases.

UNGUENTUM GALLÆ. U. S., Br.

NUTGALL OINTMENT

(*un-guën'tüm gäl'læ*)

Gall Ointment; Ointment of Galls; Pommade de Noix de Galle, *Fr.*; Galläpfelsalbe, *G.*

* "Nutmeg, in very fine powder, twenty grammes [or 309 grains]; Ointment, eighty grammes [or 2 ounces av., 360 grains], to make one hundred grammes [or 3 ounces av., 231 grains]. Rub the Nutmeg with the Ointment, gradually added, until they are thoroughly mixed. Avoid the use of metallic utensils." *U. S.*

"Galls, in very fine powder, 1 ounce (Imperial) or 30 grammes; Benzoated Lard, 4 ounces (Imp.) or 120 grammes. Mix by trituration." *Br.*

Care should be taken to have the nutgall in very fine powder and thoroughly sifted. This ointment is used chiefly in piles and pro-lapsus ani, and in flabby or indolent ulcers.

Off. Prep.—Unguentum Gallæ cum Opio, *Br.*

UNGUENTUM GALLÆ CUM OPIO. Br.

GALL AND OPIUM OINTMENT

(*un-guën'tüm gäl'læ cüm ô'pî-ô*)

"Gall Ointment, 925 grains or 92.5 grammes; Opium, in very fine powder, 75 grains or 7.5 grammes. Mix by trituration. 100 parts of this Ointment contain $7\frac{1}{2}$ parts of Opium." *Br.*

This combination of galls and opium is sometimes employed for hemorrhoids. From half a drachm to a drachm of camphor is sometimes added.

UNGUENTUM GLYCERINI PLUMBI SUBACETATIS. Br.

LEAD SUBACETATE OINTMENT

(*un-guën'tüm glyç-e-rî'nî plûm'bî sùb-âc-e-tâ'tis*)

"Glycerin of Lead Subacetate, 1 ounce (Imperial) or 30 grammes; Paraffin Ointment, white, 5 ounces (Imp.) or 150 grammes. Mix." *Br.*

This ointment has therapeutic properties similar to those of Goulard's cerate.

UNGUENTUM HAMAMELIDIS. Br.

HAMAMELIS OINTMENT

(*un-guën'tüm hãm-a-mêl'i-dis*)

Pommade de Hamamélis, *Fr.*; Hamamelissalbe, *G.*

"Liquid Extract of Hamamelis, $\frac{1}{4}$ fl. ounce (Imperial measure) or 10 cubic centimetres; Hydrous Wool Fat, $2\frac{1}{2}$ ounces (Imp.) or 90 grammes. Mix." *Br.*

This was one of the "Additions" to the British Pharmacopœia, 1885, and afterwards introduced into the *Br. Pharm.* 1898. It is, in our opinion, of doubtful utility, but may be rubbed in over sprains.

UNGUENTUM HYDRARGYRI.

U. S., Br.

MERCURIAL OINTMENT [Blue Ointment]

(*un-guën'tüm hÿ-drâr'gy-rî*)

Mercury Ointment; Unguentum Mercuriale, s. Neapolitanicum; Pommade mercurielle à parties égales. Onguent mercuriel double, Onguent Napolitain, *Fr. Cod.*; Pommade napolitaine, *Fr.*; Unguentum Hydrargyri Cinereum, *P. G.*; Graue Quecksilbersalbe, *G.*

* "Mercury, five hundred grammes [or 17 ounces av., 279 grains]; Oleate of Mercury, twenty grammes [or 309 grains]; Prepared

Suet, two hundred and thirty grammes [or 8 ounces av., 49 grains]; Benzoinated Lard, two hundred and fifty grammes [or 8 ounces av., 358 grains], to make one thousand grammes [or 35 ounces av., 120 grains]. Triturate the Oleate of Mercury in a warm mortar, add the Mercury gradually by means of a pipette, and when the globules are completely divided and distributed, set it aside for about fifteen minutes. Melt the Lard and Suet, allow the mixture to partially cool, and add about twenty-five grammes [or 386 grains] of it to the mercurial mixture, and continue the trituration until globules are no longer visible under a lens magnifying ten diameters. Then add the remainder of the Lard and Suet and mix thoroughly." *U. S.*

Assay. *U. S.* (8th Rev.)—"Weigh 10 Gm. of Mercurial Ointment in a tared dish, melt it, then remove it from the fire and add 50 Cc. of warm petroleum benzin. Stir the mixture well, allow the Mercury to settle completely, and decant the petroleum benzin. Wash the residue with successive portions of 10 Cc. each of warm petroleum benzin until it is entirely free from fatty matter, carefully retain all of the separated Mercury in the dish, and allow all traces of the benzin to evaporate. Add to the residue 10 Cc. of diluted hydrochloric acid, heat it gently and stir with a glass rod until the Mercury collects in a globule. Pour off the acid, warm the Mercury with a little distilled water, dry the globule on bibulous paper, and weigh. The Mercury should weigh not less than 4.9 Gm." *U. S.*

"Mercury, 1 pound (Imperial) or 160 grammes; Lard, 1 pound (Imp.) or 160 grammes; Prepared Suet, 1 ounce (Imp.) or 10 grammes. Triturate until metallic globules cease to be visible." *Br.*

The Pharmacopœias unite at present in recognizing but one strong mercurial ointment, which contains practically equal weights of mercury and fatty matter. When the physician wishes a weaker preparation, he may direct the ointment to be diluted with such a proportion of lard as may answer his purpose, or may use the Blue Ointment (*Unguentum Hydrargyri Dilutum*, page 1312), which contains about 33 per cent. of mercury.

The *U. S.* official formula is particularly adapted to the extemporaneous preparation of this ointment, it having been shown that the extinguishment of the mercury is facilitated by the use of oleate of mercury, while its presence undoubtedly adds to the efficiency of the ointment. Oleic acid was suggested by Leo Eliel (see *Indiana Pharmacist*, 1888) in the proportion of 1 per cent. for the extinction of the mercury. The addition of 4 per cent. of compound tincture of benzoin aids in the preservation of the ointment. The trituration should not be accompanied with pressure, a light, rapid motion of the pestle being most effective. In the preparation of mercurial ointment, care is requisite that the mercury

should be completely extinguished. The trituration is usually performed upon the large scale in a marble mortar, as it is difficult to keep iron so clean as not to impart more or less oxide to the ointment. The mercury is known to be extinguished when a portion of the mass, rubbed upon paper or the back of the hand, exhibits no metallic globules under a magnifying glass of ten diameters. The operation cannot be considered as satisfactorily accomplished when the globules are invisible merely to the naked eye. To facilitate the process, which is very tedious, the addition of various substances has been proposed, calculated to hasten the disappearance of the metal. Turpentine and sulphur have been employed, but are inadmissible,—the former because it renders the ointment too irritating, the latter because it forms with the mercury an active sulphide. Their presence in the ointment may be detected by the peculiar odor which they respectively emit when exposed to heat. Sulphur, moreover, gives the ointment a darker color. Rancidity in the lard facilitates the extinguishment of the mercury, but is liable to the same objection as turpentine, only to a greater degree. Guibourt recommended the addition of one-sixteenth of old mercurial ointment.¹ Simonin proposed the use of lard which has been exposed in thin layers to a damp air for fifteen days. This facilitates the extinguishment of the metal, but probably renders the preparation more irritant by the chemical alteration of the lard. The following plan of preparing the ointment was proposed by Chevallier. A pound of mercury, and half a pound of fresh lard, previously melted, are introduced into a stone or glass bottle, shaken till the mixture acquires the consistence of a very thick syrup, then poured into a mortar, and incorporated, by constant stirring, with an additional half-pound of lard. In this manner, according to Chevallier, a perfect ointment may be made in half an hour. E. R. Squibb prepares this ointment by succussion in an apparatus which agitates the mixture of fats and mercury until the metal is extinguished. When prepared with lard alone, the ointment is liable, in hot weather, to become so soft as to allow the metal to separate. Hence

¹ It appears that J. Higginbottom made known, so long ago as the year 1814, this mode of extinguishing mercury. He recommends that equal weights of the old ointment and of mercury should be rubbed together, till the globules quite disappear, and the requisite proportion of lard then added. It is not necessary that the mercurial ointment should be rancid. (*P. J.*, xvi. 215.) For a process recommended by J. M. Maisch, of which the peculiarity is the use of mercury passed through chamois leather, so as to be sprinkled in minute division over the fat, see *A. J. P.* (xxviii. 107), and for another by E. H. Hance, in which melted spermaceti is employed as the extinguishing material, and which is said to answer well for small quantities, see the same journal (xxix. 15). M. E. Mouchon uses wax or stearin to facilitate extinguishment, and recommends benzoinated lard as the vehicle. (*Journ. de Chim. Méd.*, Nov. 1856, p. 652.) Geo. Boyle uses a portion of old mercurial ointment and ether. (*A. J. P.*, xlv. 561.) Melseur affirms that the addition of glycerin very materially hastens the process. (*P. J.*, 1871, p. 350.)

the official use of suet, and even a larger proportion might be employed, during the summer season.¹ Christison states that the better plan is not to complete the process by a continuous trituration, but to operate for a short time every day and allow the ointment in the meantime to be exposed to the air. But so much time and labor are required in this process that the ointment is preferably made by machinery on the large scale. The fatty matters, kept in the fluid state by a heat of about 37.7° C. (100° F.), are triturated with the metal by means of two iron balls which are driven rapidly around in a circular trough by steam power. The extinguishment of the mercury is thus effected in about twelve hours. In buying from the manufacturer, great care should be exercised by the pharmacist, as much of the commercial ointment contains less than the official percentage of mercury. Indeed, it is sometimes found in the market without a trace of mercury, having been made by mixing up lamp black with rancid lard and suet until the proper tint is obtained. A method of preparing mercurial ointment proposed by Orosi is to precipitate metallic mercury, in the pulverulent form, from a solution of corrosive sublimate, by an excess of stannous chloride, with the addition of hydrochloric acid, and, having poured off the supernatant fluid, washed the precipitate with warm water, and dried it between bibulous paper, to incorporate it with the prescribed proportion of lard. To prevent the precipitated mercury from running into globules, it is recommended to cover with fat the interior of the vessel in which the precipitation takes place. For an account of many expedients that have been proposed to facilitate the extinguishment of the metal, see a paper by Dieterich (*A. J. P.*, 1880).

Mercurial ointment has when freshly prepared a bluish color, which becomes darker with age. It has been thought to contain the mercury in the state of mercurous oxide, but most of the metal can be separated by methods not calculated to reduce the oxide, and it is now generally admitted that by far the greater part of it exists in a state of minute division and not of chemical combination. It has been shown, however, that the metal is slightly oxidized, and the change of color which the ointment undergoes with age is attributable to further oxidation. If the ointment be kept long melted in a narrow vessel, metallic mercury subsides, and an oily liquid floats upon the surface. After this has been filtered so as to separate everything undissolved, it is blackened by hydrogen sulphide, and yields a trace of

mercurial oxide to acetic acid. Christison states that he has examined various samples of the ointment, and never failed to detect mercurial oxides, and he has inferred from his observations that the oxide amounts to rather more than 1 per cent. But the proportion is variable, according to the age and mode of preparation of the ointment. It scarcely admits of a doubt that the mercurial oxide formed enters into chemical combination with the lard or one of its fatty acids. Donovan advanced the idea that the medicinal activity of the ointment depended exclusively on this compound of the lard with the mercurial oxide. An ointment made by merely mixing lard and black mercurial oxide has not the same effect, however, because there is no chemical union between the ingredients. But upon exposing such a mixture to a temperature of 176.6° C. (350° F.), and continually agitating it for two hours, he found that every ounce of lard dissolved and combined with twenty-one grains of oxide, and the resulting compound was proved to be equally effectual with the common ointment, and capable of being introduced into the system in one-third of the time. It has been proposed to substitute an ointment thus prepared for that made according to the official directions, as being more manageable and of more uniform strength. Care, however, would be required in preparing it to avoid a temperature either too high or too low, as the former might decompose the oxide, and the latter would be insufficient to effect its union with the lard. There would be danger, also, that the lard might be rendered irritant by the influence of the heat. From experiments by a committee of the College of Pharmacy of New York, it appears that mercurial ointment in time becomes unequal in strength in consequence of the settling of the metallic ingredient. The inference is that, after long standing, the contents of the jar should be triturated, so as to restore an equable strength, before being dispensed. (*A. J. P.*, xvi. 2.)

Uses.—Mercurial ointment, when rubbed upon the surface of the body, produces, in consequence of its absorption, the general effects of mercury upon the system. Half to one drachm may be used at once, in urgent cases. It may also be advantageously employed as a resolvent in local affections, as in the case of *venereal buboes*, and of *chronic glandular swellings*, upon which it may be made to operate directly by being applied in the course of the absorbents passing through the enlarged glands.

In urgent cases, or in local affections, it may also be rubbed on other parts of the body, or applied to blistered surfaces. The friction should on each occasion be continued till the whole of the ointment is absorbed. When frequently rubbed upon the same part, it is prone to produce a disagreeable eruption, which interferes with its continued application. Mercurial ointment has been employed, with some

¹ *Oleum Cinereum*.—*Oleum cinereum* is a mercurial preparation used by E. Lang in syphilitic complaints. It is prepared by triturating, in a cool place, lard, oil, and mercury until the latter becomes uniformly suspended, the finished preparation to contain 20 per cent. of the metal. It is used as a local dressing, also as an injection to enlarged glands, 0.01 to 0.02 Cc. being given once a week or fortnight. For use it is melted by the warmth of the hand. (*W. K. W.*, 1886.)

success, to prevent the maturation of the *small pox pustule*, and the consequent pitting. For this purpose it may be applied to the face or other part, thickly spread on patent lint or muslin, care being taken to prevent the access of air to the covered part. To be successful it must be applied before the third or fourth day of the eruption. The ointment has been recommended also in *erysipelas* and in *chilblains*. Potassium iodide rubbed with mercurial ointment is said to promote the separation of the mercury in the form of globules (*J. P. C.*, 3e sér., x. 356); but the effect will not take place if the iodide has been thoroughly dried and well powdered and the ointment is added to it in small portions at a time. (*Ibid.*, x. 421.)

Off. Prep.—Linimentum Hydrargyri, *Br.*; Unguentum Hydrargyri Compositum, *Br.*; Unguentum Hydrargyri Dilutum, *U. S.*

UNGUENTUM HYDRARGYRI AMMONIACI. *U. S., Br.*

OINTMENT OF AMMONIATED MERCURY

(*un-guén'tüm hý-drär'gy-rí am-mō-ní-á'ti*)

White Precipitate Ointment; Unguentum Præcipitæ Albi; Ointment of White Precipitate; Pommade de Chloramide de Mercure, *Fr.*; Unguentum Hydrargyri Album, *P. G.*; Weisse Quecksilbersalbe, *G.*

* “Ammoniated Mercury, in very fine powder, *ten grammes* [or 154 grains]; White Petrolatum, *fifty grammes* [or 1 ounce av., 334 grains]; Hydrous Wool-Fat, *forty grammes* [or 1 ounce av., 180 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Rub the Ammoniated Mercury with an equal weight of the melted White Petrolatum, then add the remainder of the melted White Petrolatum, mix thoroughly with the Hydrous Wool-Fat, and stir the mixture until it congeals.” *U. S.*

“Ammoniated Mercury, 1 ounce (Imperial) or 30 grammes; Paraffin Ointment, white, 9 ounces (Imp.) or 270 grammes. Mix.” *Br.*

Used chiefly in cutaneous eruptions, such as *psora*, *porrigo*, and *herpes*.

UNGUENTUM HYDRARGYRI COMPOSITUM. *Br.*

COMPOUND MERCURY OINTMENT

(*un-guén'tüm hý-drär'gy-rí com-pōs'it-tüm*)

Pommade mercurielle composée, *Fr.*; Kampher Quecksilbersalbe, *G.*

“Mercury Ointment, 10 ounces (Imperial) or 150 grammes; Yellow Beeswax, 6 ounces (Imp.) or 90 grammes; Olive Oil, 6 ounces (Imp.) or 90 grammes; Camphor, in flowers, 3 ounces (Imp.) or 45 grammes. Mix the Beeswax, Olive Oil, and Mercury Ointment with the aid of heat; add the Camphor; triturate until cold.” *Br.*

The addition of camphor to mercurial ointment has been thought to soften it and promote absorption of the mercury, but that it has such an effect is very doubtful.

UNGUENTUM HYDRARGYRI DILUTUM. *U. S.*

BLUE OINTMENT

(*un-guén'tüm hý-drär'gy-rí di-lú'tüm*)

* “Mercurial Ointment, *six hundred and seventy grammes* [or 23 ounces av., 207 grains]; Petrolatum, *three hundred and thirty grammes* [or 11 ounces av., 280 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Mix them thoroughly.” *U. S.*

This ointment was introduced into the *U. S. P.* (8th Rev.) to supply the need for a weaker preparation than the official 50 per cent. ointment (see *Unguentum Hydrargyri*); it should be kept in a cool place in the summer, as otherwise the mercury may separate on account of the softening of the fatty vehicle.

UNGUENTUM HYDRARGYRI IODIDI RUBRI. *Br.*

MERCURIC IODIDE OINTMENT

(*un-guén'tüm hý-drär'gy-rí i-ód'ý'di rá'bri*)

Ointment of Red Iodide of Mercury; Pommade d'Iodure Mercurique, Pommade de Deutiodure de Mercure, *Fr.*; Jodquecksilbersalbe, *G.*

“Mercuric Iodide, in fine powder, 20 grains or 2 grammes; Benzoated Lard, 480 grains or 48 grammes. Mix.” *Br.*

This ointment is employed as a dressing to indolent *scrofulous* and *syphilitic* ulcers.

UNGUENTUM HYDRARGYRI NITRATIS. *U. S., Br.*

OINTMENT OF MERCURIC NITRATE CITRINE OINTMENT

(*un-guén'tüm hý-drär'gy-rí ní-trá'tis*)

Unguentum Citrinum; Unguentum Hydrargyri Citrinum; Pommade Citrine, *Fr. Cod.*; Onguent Citrin, Pommade de Nitrate de Mercure, *Fr.*; Quecksilber-nitratsalbe, Gelbe Quecksilbersalbe, *G.*

* “Mercury, *seventy grammes* [or 2 ounces av., 205 grains]; Nitric Acid, *one hundred and seventy-five grammes* [or 5 ounces av., 76 grains]; Lard, free from water, *seven hundred and sixty grammes* [or 26 ounces av., 354 grains], to make about *one thousand grammes* [or 35 ounces av., 120 grains]. Heat the Lard in a capacious glass or porcelain vessel to a temperature of 105° C. (221° F.), then withdraw the heat and gradually add *seventy grammes* [or 2 ounces av., 205 grains] of the Nitric Acid. When the reaction moderates, reapply the heat until effervescence ceases, and allow the mixture to cool to about 40° C. (104° F.). Having dissolved the Mercury in the remainder of the Nitric Acid, using sufficient heat to prevent the solution from crystallizing, add this solution to the Lard mixture. When the mass begins to congeal, stir it thoroughly with a wooden spatula, until it is of a bright citrine color. Contact with metallic utensils should be avoided.” *U. S.*

"Mercury, 1 ounce (Imperial) or 100 grammes; Nitric Acid, 3 *fl. ounces* (Imp. meas.) or 300 cubic centimetres; Lard, 4 *ounces* (Imp.) or 400 grammes; Olive Oil, 7 *ounces* (Imp.) or 700 grammes. Dissolve the Mercury in the Nitric Acid without the aid of heat, agitating gently from time to time. Heat the Lard and Olive Oil together on a sand-bath, so that the mixture when transferred to a heated earthenware jar, capable of holding ten times the quantity, shall be at a temperature of 290° F. (143.3° C.). Add the cold mercurial solution very gradually, stirring constantly to promote disengagement of the fumes. After frothing has ceased, the mixture, which should have a temperature of not less than 200° F. (93.3° C.), must be kept stirred until it is cold. The resulting Ointment should be firm in consistence and have a pale lemon color." *Br.*

The formula for this ointment was changed in the U. S. P. (8th Rev.) by replacing the lard oil with lard; this in our opinion is not an improvement, as the present ointment is too hard in cold weather and more disposed to granulate than the ointment of the U. S. P. 1890. The introduction of a diluted citrine ointment into the Pharmacopœia similar to the one in the British Pharmacopœia would prove a great convenience.

The chemical changes which take place in the preparation of this ointment are not precisely known. They differ somewhat according to the circumstances under which the operation is performed; for example, according to the proportion and strength of the acid, the nature of the fatty matter, and the degree of heat employed. In the British process and that of the U. S. P. 1870 the mercury, in the first step of the process, is converted into a mixture of mercuric and mercurous nitrate by the addition of nitric acid in excess, with the loss of some of the free nitric acid through deoxidation. When the acid mercurial solution is added to the fatty matter, a reaction takes place, which results in the fat being oxidized at the expense of the free nitric acid, nitrogen dioxide and nitrogen tetroxide being at the same time liberated, and the olein of the fat is converted into elaidin, which change is recognized by the beautiful orange color of the fat. But the degree to which these changes take place is influenced greatly by the temperature to which the mixture is exposed. If this be low, there is little or no escape of gas; if elevated, there is a copious evolution of nitrous fumes. In the former case the changes are obviously less considerable than in the latter.

As formerly prepared, this ointment, though at first beautifully yellow and of the proper consistence, soon began to change, acquiring in time a dirty-greenish and mottled color, and becoming so hard and friable as to be unfit for use unless mixed with lard. These results were ascribed to various causes, and many different modifications of the process were proposed in order to obviate them. The U. S.

process of 1850 was based upon the fact that the olive oil of the former British process is hardened by nitrous acid or mercuric nitrate, while the same effect is not produced upon neat's-foot oil. As at first published, the process was defective in the direction to add the mercurial solution to the mixed oleaginous fluid when it begins to stiffen on cooling. When this direction was complied with, at least with the acid of the ordinary strength, the preparation had a brown color and a semi-liquid consistence, but with some modifications, such as were introduced into the revised formula of the Pharmacopœia of 1860, the process yielded an excellent ointment, which, though it sometimes assumed a greenish color on exposure, retained permanently a soft unctuous consistence. We have had specimens of the ointment in our possession for several years which have retained a uniform yellowish color and a perfectly good unctuous consistence. R. Rother, however, affirmed that the fault was not in the components, but in the processes of the official formula of 1870 (*A. J. P.*, xlii. 420), especially in the use of too high a temperature,¹ and these views have been confirmed by ample experience. The present official process was based on Rother's formula, and the value of this process lies principally in the fact that the olein of the oil is first converted into elaidin by the addition of nitric acid alone and the application of heat, and when the reaction has ceased and the basis of citrine ointment, as it might be called, is prepared, and nearly cold, the mercurial solution is added. In this way decomposition of the mercuric nitrate is avoided, as it is not subjected to heat, and the result is an ointment which will retain its color and consistence a long time. The drying vegetable oils appear, like olive oil, to be converted by nitrous acid or mercuric nitrate into elaidin, and it was a fair inference that they might be employed advantageously in the preparation of citrine ointment. Accordingly, Fessenden of North Carolina, stated, in an inaugural essay, that he substituted linseed oil for the neat's-foot oil, and succeeded in obtaining a perfectly good and durable ointment. Falières has found the oil of the ground nut (*Arachis hypogæa*) to answer very well. (*P. J.*, 1873, p. 1031.) Purified cotton seed oil makes an excellent vehicle. Washed butter is frequently used as the fat.

¹ R. Rother's formula is as follows: "Take of Mercury 1½ troyounces; Nitric Acid, sp. gr. 1.42, 3½ troyounces; Lard, pure, 16½ troyounces. Dissolve the Mercury in 900 grains of the Nitric Acid, with the aid of heat, and keep the solution gently warm to prevent crystallization before it is used. Melt the Lard in a suitable vessel, with a moderate heat; then add the remainder of the Nitric Acid, and continue the heat, without stirring the mixture, as long as moderate effervescence continues; but if this becomes too violent, remove the mixture from the fire, and replace it only when the action slackens too much. Finally, when effervescence ceases, and the liquid only boils even under an increased heat, remove the mixture from the fire altogether; and when it begins to stiffen, add the mercurial solution and mix thoroughly." (*A. J. P.*, xlii. 420.) (For a formula in which neat's-foot oil is used, asserted by Thos. J. Covell to be superior to the official, and for a bibliography of the subject, see *A. J. P.*, xlii. 211.)

In the British process, when the fatty matter and the mercurial solution are mixed, care must be taken that the heat applied be not too great. Gas is extricated at 82.2° C. (180° F.), and at 100° C. (212° F.) escapes so abundantly that the mixture boils over unless the vessel is very large. (Alsop.) Besides, if the heat be too great, a portion of the mercury will be reduced, and the color of the ointment impaired. When large quantities of materials are operated upon, the reaction which occurs produces of itself a sufficient heat, but in ordinary cases the temperature should be kept at about 87.7° C. (190° F.) by means of a water bath, and if it exceed 96.1° C. (205° F.) should be reduced. It should always be sufficient to produce a copious extrication of gas. The ointment should be prepared in a glass, porcelain, or well-glazed earthen vessel, and a glass rod or a wooden spatula should be employed for stirring the mixture. Under no circumstances should an iron or steel spatula or stirrer be used in its preparation, because of the discoloration due to the action of the acid upon the iron.

Uses.—This ointment is much and very advantageously employed, as a stimulant and alterative application, in *porrigo* or *tinea capitis*, *impetigo larvalis* or *crusta lactea*, *psoriasis* and *pityriasis*, certain forms of *chronic eczema*, *psorophthalmia* and *inflammation of the eye and eyelids* connected with *porrigo* of the face or scalp, and various other *ulcerative* and *eruptive affections*. It should be diluted with lard, unless in cases which require a very stimulant application. Some care is requisite in its use, to avoid the risk of salivation. When hard and friable, it must be rubbed up with fresh lard before it can be applied. An ointment prepared with lard and nitric acid, called *Alyon's ointment*, after the person who first prepared it, was formerly much used in cases similar to those in which the citrine ointment is now employed. The *ointment of nitric acid* of the former Edinburgh and Dublin Pharmacopœias was of this character.

Off. Prep.—Unguentum Hydrargyri Nitratis Dilutum, Br.

UNGUENTUM HYDRARGYRI NITRATIS DILUTUM. Br.

DILUTED MERCURIC NITRATE OINTMENT

(un-guën'tüm hÿ-drär'gy-ri ni-trä'tis di-lütüm)

"Mercuric Nitrate Ointment, 1 ounce (Imperial) or 25 grammes; Soft Paraffin, yellow, 4 ounces (Imp.) or 100 grammes. Mix." Br.

UNGUENTUM HYDRARGYRI OLEATIS. Br.

MERCURIC OLEATE OINTMENT

(un-guën'tüm hÿ-drär'gy-ri ô-lë-ä'tis)

Pommade d'Oléate Mercurique, Fr.; Quecksilber-oleatsalbe, G.

"Mercuric Oleate, 1 ounce (Imperial) or 20 grammes; Benzoated Lard, 3 ounces (Imp.) or 60 grammes. Mix." Br.

UNGUENTUM HYDRARGYRI OXIDI FLAVI. U. S., Br.

OINTMENT OF YELLOW MERCURIC OXIDE

(un-guën'tüm hÿ-drär'gy-ri ôx'i-di flä'vî)

Yellow Mercuric Oxide Ointment; Pommade d'oxyde mercurique jaune, Fr.; Gelbe Quecksilberoxydsalbe, G.

* "Yellow Mercuric Oxide, in very fine powder, ten grammes [or 154 grains]; Water, ten grammes [or 154 grains]; Hydrous Wool-Fat, forty grammes [or 1 ounce av., 180 grains]; Petrolatum, forty grammes [or 1 ounce av., 180 grains], to make one hundred grammes [or 3 ounces av., 231 grains]. Triturate the Yellow Mercuric Oxide with the Water until the mixture is perfectly smooth, then add the Hydrous Wool-Fat in divided portions, and incorporate thoroughly with the Petrolatum, avoiding contact with metallic utensils." U. S.

"Yellow Mercuric Oxide, in very fine powder, 10 grains or 0.5 gramme; Soft Paraffin, yellow, 490 grains or 24.5 grammes. Mix." Br.

The U. S. P. (8th Rev.) process is an improvement over the former U. S. P. 1890 method because of the use of water, hydrous wool-fat and petrolatum in place of simple ointment.

The unctuous vehicle of this ointment, without being so liquid as to allow the powder to subside, must yet melt at the heat of the body, and thus, when introduced into the eye, spread equally over the surface. It should, moreover, be as far as possible chemically indifferent to the oxide, and, while perfectly bland in its proper state, should not be liable to become irritating by rancidity. For medicinal properties, see *Unguentum Hydrargyri Oxidi Rubri*.

UNGUENTUM HYDRARGYRI OXIDI RUBRI. U. S., Br.

OINTMENT OF RED MERCURIC OXIDE

[Red Precipitate Ointment]

(un-guën'tüm hÿ-drär'gy-ri ôx'i-di rû'bri)

Unguentum Precipitati Rubri; Pommade d'oxyde rouge de Mercure, Fr. Cod.; Pommade de Lyon, Pommade de Précipité rouge, Baume ophtalmique rouge, Fr.; Unguentum Hydrargyri Rubrum, P. G.; Rothe Quecksilbersalbe, G.

* "Red Mercuric Oxide, in very fine powder, ten grammes [or 154 grains]; Water, ten grammes [or 154 grains]; Hydrous Wool-Fat, forty grammes [or 1 ounce av., 180 grains]; Petrolatum, forty grammes [or 1 ounce av., 180 grains], to make one hundred grammes [or 3 ounces av., 231 grains]. Triturate the Red Mercuric Oxide with the Water until the mixture is perfectly smooth and absolutely free from gritty particles, then add the Hydrous

Wool-Fat in divided portions, and incorporate thoroughly with the Petrolatum. Contact with metallic utensils should be avoided." *U. S.*

"Red Mercuric Oxide, in very fine powder, $\frac{1}{2}$ ounce (Imperial) or 10 grammes; Paraffin Ointment, yellow, $2\frac{1}{2}$ ounces (Imp.) or 90 grammes. Mix." *Br.*

The red mercuric oxide here referred to is that prepared from the nitrate and usually called *red precipitate*. It is important that the oxide should be thoroughly pulverized before being mixed with the lard, as otherwise it might prove injurious in cases of ophthalmia, in which it is sometimes used. When great care is taken to have the red oxide very finely pulverized, the color is more yellowish than is usual. This ointment loses its fine red color when long kept, probably in consequence of the conversion of the red oxide into the black, or its reduction to the metallic state. It is best to prepare it in small quantities at a time. We have been informed that if the preparation be made by mixing the red oxide with poplar bud ointment it will keep a long time without change. According to R. H. Stabler of Alexandria, Va., an equally effectual method is to mix two drops of solution of potassium hydroxide with each ounce of the ointment when prepared (*A. J. P.*, xxiii. 123); but Julius Kalish states that this is not effectual. Emil Martin states that if a mixture of six parts of castor oil to two of wax be used as the basis of the ointment the red color will remain unchanged for years. (*A. J. P.*, xlv. 202.) Kalish substitutes oil of sweet almond for the castor oil, on account of the unpleasant odor of the latter. (*A. J. P.*, xlv. 69.) The *U. S. P.* (8th Rev.) process is an improvement over the process of the *U. S. P.* 1890 particularly in the choice of the vehicle. Ointment of red mercuric oxide is a highly useful stimulating ointment, much employed in *indolent and foul ulcers*, in *porrigo* of the scalp, and in *psorophthalmia* and *chronic conjunctival ophthalmia*, especially when attended with thickening of the inner membrane of the eyelids, or with specks upon the cornea, but it is rapidly being supplanted by the ointment of yellow mercuric oxide, because the latter can be made smoother and less irritating, and has the same chemical composition and properties. It may be diluted with lard if found too stimulating.

UNGUENTUM HYDRARGYRI SUBCHLORIDI. Br.

MERCUROUS CHLORIDE OINTMENT

(*yn-guën'tüm hÿ-drär'gy-rî süb-chlô'rî-dî*)

Unguentum Calomelanos, *Br.* 1864; Ointment of Subchloride of Mercury; Ointment of Calomel; Pommade de Chlorure Mercureux, Pommade de Calomel, Pommade de Calomélas, *Fr.*; Quecksilberchlorürsalbe, *G.*

"Mercurous Chloride, $\frac{1}{2}$ ounce (Imperial) or 10 grammes; Benzoated Lard, $2\frac{1}{2}$ ounces (Imp.) or 90 grammes. Mix." *Br.*

There is little occasion for such a preparation as this. Calomel is much inferior to the mercurial ointment for affecting the system by inunction, and as an application to ulcerated surfaces the form of cerate would be better. It may, however, be useful in certain *cutaneous eruptions*.

UNGUENTUM IODI. U. S., Br.

IODINE OINTMENT

(*yn-guën'tüm i-ô'dî*)

Unguentum Iodinii, *U. S.* 1870; Pommade d'Iodure de potassium iodure, *Fr. Cod.*; Pommade d'Iode, *Fr.*; Jodsalbe, *G.*

* "Iodine, *four grammes* [or 62 grains]; Potassium Iodide, *four grammes* [or 62 grains]; Glycerin, *twelve grammes* [or 185 grains]; Benzoinated Lard, *eighty grammes* [or 2 ounces av., 360 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Triturate the Iodine and Potassium Iodide in a glass mortar with the Glycerin until dissolved, then gradually incorporate the Benzoinated Lard and mix thoroughly, avoiding the use of a metallic spatula. This Ointment should be freshly made when required." *U. S.*¹

"Iodine, *20 grains* or 1 gramme; Potassium Iodide, *20 grains* or 1 gramme; Glycerin, *60 grains* or 3 grammes; Lard, *400 grains* or 20 grammes. Triturate the Iodine, Potassium Iodide, and Glycerin, in a glass or porcelain mortar; add the Lard gradually. Mix." *Br.*

The object of the potassium iodide and water in the *U. S.* 1890 process was to bring the iodine into a state in which it may be equably incorporated with the lard. They were found to answer better in practice than the alcohol formerly used, but glycerin, as directed in the *U. S. Pharm.* (8th Rev.) process, answers still better.

The proportion of potassium iodide was increased from 1 Gm. to 4 Gm. in the *U. S. P.* (8th Rev.) and glycerin (12 per cent.) added. When rubbed upon the skin it imparts to it an orange color, which, however, slowly disappears with the evaporation of the iodine. It is useful as a local application in *goitre*, *scrofulous swellings of the glands*, and other *chronic tumefactions*, internal or external, operating probably through the medium of absorption. When continued for some time it occasionally produces a pustular eruption upon the portion of skin to which it is applied. It has also been recommended in *chilblains*. The ointment should be prepared only when wanted for use, for it undergoes change if kept, losing its deep orange-brown color, and becoming pale upon its surface.

¹ *Unguentum Iodinii Compositum. U. S.* 1870. "Take of Iodine *fifteen grains*; Iodide of Potassium *thirty grains*; Water *thirty minims*; Lard *a troy-ounce*. Rub the Iodine and Iodide of Potassium first with the Water, and then with the Lard, until they are thoroughly mixed." *U. S.* 1870.

UNGUENTUM IODOFORMI. U. S., Br.**ODOFORM OINTMENT**

(ṽn-ḡuēn'tūm i-ḡ-d-ḡ-fōr'mi)

Pommade d'Iodoforme, *Fr.*; Iodoformsalbe, *G.*

* "Iodoform, in very fine powder, *ten grammes* [or 154 grains]; Lard, *ninety grammes* [or 3 ounces av., 76 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Triturate the Iodoform thoroughly with about twice its weight of the Lard, then incorporate the remainder of the Lard." *U. S.*

"Iodoform, in fine powder, $\frac{1}{2}$ ounce (Imperial) or 10 grammes; Paraffin Ointment, yellow, $2\frac{1}{2}$ ounces (Imp.) or 90 grammes. Mix." *Br.*

It is important to have the iodoform in very fine powder, as officially directed, and, owing to the powerful odor of iodoform, it is usual to add oil of bitter almond or one of the other volatile oils, balsam of Peru, or a similar substance, to render the odor more bearable.

UNGUENTUM PARAFFINI. Br.**PARAFFIN OINTMENT**

(ṽn-ḡuēn'tūm pār-āf-fī-ni)

Pommade de Paraffin, *Fr.*; Paraffinsalbe, *G.*

"Hard Paraffin, 3 ounces (Imperial) or 90 grammes; Soft Paraffin, 7 ounces (Imp.) or 210 grammes. Melt together in a shallow evaporating dish; as the liquid cools triturate constantly, until, when cold, a uniform plastic ointment is produced. When Paraffin Ointment is used as the basis of white ointments, it should be prepared with the white variety of Soft Paraffin; and when used in colored ointments it should be prepared with the yellow variety of Soft Paraffin. The proportions of Hard and Soft Paraffins in Paraffin Ointment may be modified to meet the exigencies of climate and prevailing temperature." *Br.*

This was recognized by the *Br. Ph.* 1898 for use as a vehicle in the exhibition of various medicaments; its power of absorption is limited and inferior to oleic acid or lard.

Off. Prep.—Unguentum Acidi Borici, *Br.*; Unguentum Acidi Carbolici, *Br.*; Unguentum Acidi Salicylici, *Br.*; Unguentum Glycerini Plumbi Subacetatis, *Br.*; Unguentum Hydrargyri Ammoniaci, *Br.*; Unguentum Hydrargyri Oxidi Rubri, *Br.*; Unguentum Iodoformi, *Br.*; Unguentum Plumbi Acetatis, *Br.*; Unguentum Plumbi Carbonatis, *Br.*; Unguentum Plumbi Iodidi, *Br.*

UNGUENTUM PHENOLIS. U. S. (Br.)

OINTMENT OF PHENOL [Unguentum Acidi Carbolici, *Pharm.* 1890, Ointment of Carbolic Acid]

(ṽn-ḡuēn'tūm phē-nō-lis)

Unguentum Acidi Carbolici, *Br.*; Pommade de Phénol, Pommade Phéniquée, Pommade d'Acide phénique, *Fr.*; Karbolsalbe, Phenolsalbe, *G.*

* "Phenol, *three grammes* [or 46 grains]; White Petrolatum, *ninety-seven grammes* [or 3

ounces av., 184 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. To the melted White Petrolatum add the Phenol, and stir the mixture until it begins to congeal." *U. S.*

"Phenol, $\frac{1}{2}$ ounce (Imperial) or 15 grammes; Glycerin, $1\frac{1}{2}$ ounces (Imp.) or 45 grammes; Paraffin Ointment, white, $10\frac{1}{2}$ ounces (Imp.) or 315 grammes. Dissolve the Phenol in the Glycerin; add the Paraffin Ointment. Mix." *Br.*

The quantity of phenol in this ointment was decreased from 10 per cent. in the *U. S. P.* 1880 to 5 per cent. in the 1890 revision, and has been further decreased to 3 per cent. in the *U. S. P.* (8th Rev.). This is an improvement, for it is a very strong ointment, which for most purposes still requires dilution.

UNGUENTUM PICIS LIQUIDÆ.**U. S., Br.****TAR OINTMENT**

(ṽn-ḡuēn'tūm pī'cis liq'ui-dæ)

Pommade de Goudron, *Fr. Cod.*; Theersalbe, *G.*

* "Tar, *five hundred grammes* [or 17 ounces av., 279 grains]; Yellow Wax, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Lard, *three hundred and fifty grammes* [or 12 ounces av., 151 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Melt the Yellow Wax, add the Lard, and to the melted mixture add the Tar, previously warmed, and incorporate thoroughly; strain through muslin, and stir the mixture until it congeals." *U. S.*

"Tar, 5 ounces (Imperial) or 100 grammes; Yellow Beeswax, 2 ounces (Imp.) or 40 grammes. Melt the Beeswax at a low temperature; add the Tar; stir the mixture until cold." *Br.*

The formula for tar ointment in the *U. S. P.* 1890 differed from that formerly official in the use of yellow wax and lard in place of suet. The same ingredients were retained in the Eighth Revision, but the proportion of wax was slightly decreased making the ointment somewhat softer in consistence. This ointment is highly useful as a stimulant application in various *scaly* and *scabby eruptions*, particularly in *psoriasis* and *lepra*, and in that form of *porrigo* usually called *tinea capitis*, or *scald-head*. In the last-mentioned affection it should be applied night and morning, and in bad cases the patient should constantly wear a cap thickly coated internally with the ointment.

UNGUENTUM PLUMBI ACETATIS. Br.**LEAD ACETATE OINTMENT**

(ṽn-ḡuēn'tūm plūm'bī āc-ē-tā'tis)

Pommade d'Acétate de Plomb, *Fr.*; Bleizuckersalbe, *G.*

"Lead Acetate, in fine powder, 20 grains or 2 grammes; Paraffin Ointment, white, 480 grains or 48 grammes. Mix." *Br.*

An official preparation of the Br. Pharmacopœia, used as a dressing for *inflamed and excoriated surfaces*, though inferior, we think, to the cerate of the subacetate.

UNGUENTUM PLUMBI CARBONATIS. Br.

LEAD CARBONATE OINTMENT

(*un-guên'tũm plũm'bi cār-bō-nā'tis*)

Ointment of White Lead: Pommade de Carbonate de Plomb, *Fr. Cod.*; Onguent blanc de Rhazès, Pomade de Céruse, *Fr.*; Unguentum Cerussæ, *P. G.*; Bleiweissalbe, *G.*

"Lead Carbonate, in fine powder, $\frac{1}{2}$ ounce (Imperial) or 10 grammes; Paraffin Ointment, white, $2\frac{1}{2}$ ounces (Imp.) or 90 grammes. Mix." *Br.*

This ointment, which is no longer official in the U. S. P. (8th Rev.) (see page 1304), is used as a dressing to *blistered or excoriated surfaces, burns, etc.*

UNGUENTUM PLUMBI IODIDI. Br.

LEAD IODIDE OINTMENT

(*un-guên'tũm plũm'bi i-ôd'i-dĩ*)

Lead Iodide Ointment: Pommade d'Iodure de Plomb, *Fr. Cod.*; Jodbleisalbe, *G.*

"Lead Iodide, in fine powder, $\frac{1}{2}$ ounce (Imperial) or 10 grammes; Paraffin Ointment, yellow, $2\frac{1}{2}$ ounces (Imp.) or 90 grammes. Mix." *Br.*

For the uses of this ointment, see *Plumbi Iodidum*.

UNGUENTUM POTASSII IODIDI. U. S., Br.

OINTMENT OF POTASSIUM IODIDE

(*un-guên'tũm pō-tās'si-i i-ôd'i-dĩ*)

Potassium Iodide Ointment: Pommade d'Iodure de Potassium, *Fr. Cod.*; Unguentum Kalii jodati, *P. G.*; Jodkaliumsalbe, Kaliumjodidsalbe, *G.*

* "Potassium Iodide, *ten grammes* [or 154 grains]; Potassium Carbonate, *six-tenths of a gramme* [or 9 grains]; Water, *ten grammes* [or 154 grains]; Benzoated Lard, *eighty grammes* [or 2 ounces av., 360 grains], to make about *one hundred grammes* [or 3 ounces av., 231 grains]. Dissolve the Potassium Iodide and Potassium Carbonate in the Water by trituration, then gradually add the Benzoated Lard and incorporate thoroughly. This Ointment should be prepared extemporaneously." *U. S.*

"Potassium Iodide, 50 grains or 5 grammes; Potassium Carbonate, 3 grains or 0.3 gramme; Distilled Water, 47 grains or 4.7 grammes; Benzoated Lard, 400 grains or 40 grammes. Dissolve the Potassium Iodide and Potassium Carbonate in the Distilled Water; mix the solution, gradually, with the Benzoated Lard, in a slightly warmed mortar." *Br.*

The U. S. preparation of 1870 was likely to become discolored by time in consequence of the liberation of iodine. This was due to rancidity in the lard, and the slightest change in the fat would produce some discoloration. It was prevented in the U. S. P. 1880 by the sodium thiosulphate, which also produces traces of sodium iodide and sulphur. It is said that the same object may be attained by mixing two drops of solution of potassium hydroxide with each ounce of the freshly prepared ointment. (*A. J. P.*, xxiii. 123.) The addition of potassium carbonate by the present U. S. and Br. Pharmacopœias is made with this object.

The *Bulletin de Pharmacie du Nord* recommended a concentrated solution of potassium iodide in glycerin as a basis for this ointment. One gramme of the salt is dissolved in two and a half grammes of hot glycerin, and the solution mixed with the fatty constituent in the proper proportion. The advantages of this method are that the ointment is free from crystals, and the salt more readily absorbed. The glycerin would probably not be objectionable in most cases, and potassium carbonate could be added, if desired. Ointment of potassium iodide is employed for the discussion of *goitres, scrofulous tumors*, and other *indolent swellings*, and is sometimes preferred to the ointment of iodine, as it does not, like that, discolor the skin.

UNGUENTUM STAPHISAGRIÆ. Br.

STAVESACRE OINTMENT

(*un-guên'tũm stāph-i-sā'grī-æ*)

Onguent de Staphisaigre, *Fr.*; Stephanskörnersalbe, *G.*

"Stavesacre Seeds, 2 ounces (Imperial) or 40 grammes; Yellow Beeswax, 1 ounce (Imp.) or 20 grammes; Benzoated Lard, $8\frac{1}{2}$ ounces (Imp.) or 170 grammes. Crush the Stavesacre Seeds; digest the crushed seeds with the Benzoated Lard on a water-bath for two hours; strain and press through calico; add the Beeswax to the liquid; heat gently to dissolve; stir until cold." *Br.*

This ointment is but half the strength of that official in the British Pharmacopœia 1885; it is said to be non-irritant, and is largely used in Great Britain for destroying *body-lice*, also in *scabies, prurigo* and some other *cutaneous affections*.

UNGUENTUM STRAMONII. U. S.

STRAMONIUM OINTMENT

(*un-guên'tũm strā-mō'nī-i*)

Pommade de Stramoine, *Fr.*; Stechapfelsalbe, *G.*

* "Extract of Stramonium, *ten grammes* [or 154 grains]; Diluted Alcohol, *five cubic centimeters* [or 81 minims]; Hydrous Wool-Fat, *twenty grammes* [or 309 grains]; Benzoated

Lard, *sixty-five grammes* [or 2 ounces av., 128 grains], to make about *one hundred grammes* [or 3 ounces av., 231 grains]. Triturate the Extract with the Diluted Alcohol until a smooth mixture is obtained; with this incorporate the Hydrous Wool-Fat, then add the Benzoinated Lard, and mix thoroughly." *U. S.*

This is a more certain preparation than that of the former editions of the U. S. Pharmacopœia, which was made by boiling the fresh leaves in lard. The color of the ointment of the U. S. P. (8th Rev.) is different from that of the former Pharmacopœia, the greenish tint being due to the use of official extract of stramonium which is now made from the leaves instead of the seeds. For remarks by A. P. Sharp of Baltimore, on the preparation of this ointment, see *A. J. P.* (xxvii. 391). A useful anodyne application in *irritable ulcers, painful hemorrhoids, and certain cutaneous eruptions.*

UNGUENTUM SULPHURIS. U. S., Br.

SULPHUR OINTMENT

(un-guën'tüm sül'phù-ris)

Pomatum Sulfuratum, Unguentum Sulfuratum Simplex; Pomade Soufrée, *Fr. Cod.*; Schwefelsalbe, *G.*

* "Washed Sulphur, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Benzoinated Lard, *eight hundred and fifty grammes* [or 29 ounces av., 430 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Rub the Washed Sulphur with the Benzoinated Lard, gradually added, until they are thoroughly mixed." *U. S.*

"Sublimed Sulphur, finely sifted, *1 ounce* (Imperial) or 30 grammes; Benzoated Lard, 9 ounces (Imp.) or 270 grammes. Mix." *Br.*

Washed sulphur was substituted in the U. S. P. 1890 for the sublimed sulphur of the former Pharmacopœia; the change is of questionable utility, as the products resulting from the slight decomposition in sublimed sulphur have value as parasitocides. In the U. S. P. (8th Rev.) the percentage of sulphur was reduced one-half. Sulphur ointment is a specific for the *itch*. It should be applied every night over the whole surface till the complaint is cured. Four applications are generally sufficient to effect a cure. Sulphur ointment applied freely over the *variolous eruption* in its early stage is said to prevent the maturation of the pustules and the consequent pitting. Its disagreeable odor may be partially concealed by oil of lemon or oil of bergamot.¹

¹ *Unguentum Sulphuris Alkalinum*. U. S. 1880. *Alkaline Sulphur Ointment*.—"Washed Sulphur, *twenty parts* [or ninety-six grains]; Carbonate of Potassium, *ten parts* [or forty-eight grains]; Water, *five parts* [or half a fluidrachm]; Benzoinated Lard, *sixty-five parts* [or three hundred and twelve grains], to make *one hundred parts* [or about one ounce]. Rub the Sulphur with the Carbonate of Potassium and the Water, gradually add the Benzoinated Lard, and mix thoroughly." *U. S.* 1880. This ointment, dropped at the U. S. P. 1890 revision, is useful in scabies and other skin affections.

UNGUENTUM SULPHURIS IODIDI. Br.

SULPHUR IODIDE OINTMENT

(un-guën'tüm sül'phù-ris i-öd'i-di)

Pommade d'Iodure de Soufre, *Fr.*; Jodschwefelsalbe, *G.*

"Sulphur Iodide, *20 grains* or 2 grammes; Glycerin, *20 grains* or 2 grammes; Benzoated Lard, *460 grains* or 46 grammes. Triturate the Sulphur Iodide and Glycerin in a slightly warmed mortar until a smooth paste results; gradually add the Benzoated Lard; stir until cold." *Br.*

This ointment is no longer official in the U. S. Pharmacopœia; that of the U. S. P. 1870 was made by rubbing thirty grains of sulphur iodide with a troyounce of lard, gradually added, until thoroughly mixed.

This is admirably adapted, as a local remedy, to the treatment of *chronic cutaneous eruptions* unattended with inflammation, and is especially useful in *psoriasis, lepra, porrigo*, and in the very advanced dry stages of *eczema* and of *impetigo*.

UNGUENTUM VERATRINÆ. U. S., Br.

VERATRINE OINTMENT

(un-guën'tüm vēr-ā-trī-næ)

Unguentum Veratrine, U. S. 1870; Pomade de Veratrine, *Fr.*; Veratrinsalbe, *G.*

* "Veratrine, *four grammes* [or 62 grains]; Expressed Oil of Almond, *six grammes* [or 93 grains]; Benzoinated Lard, *ninety grammes* [or 3 ounces av., 76 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Rub the Veratrine with the Expressed Oil of Almond, then gradually add the Benzoinated Lard, and mix thoroughly." *U. S.*

"Veratrine, *10 grains* or 0.5 gramme; Oleic Acid, *40 grains* or 2 grammes; Lard, *450 grains* or 22.5 grammes. Rub the Veratrine with the Oleic Acid, and gently warm the mixture until dissolved; add the Lard. Mix." *Br.*

For the uses of Veratrine ointment, see *Veratrina* and *Oleatum Veratrinæ*. Notice should be taken of the fact that the U. S. ointment is twice as strong as the British. It should be employed with caution, and not brought in contact with abraded skin surfaces nor applied too freely to sound skin, especially in the case of children.

UNGUENTUM ZINCI OLEATIS. Br.

ZINC OLEATE OINTMENT

(un-guën'tüm zin'ci ò-lē-ā'tis)

Pommade d'oleate de zinc, *Fr.*; Zink oleatsalbe, *G.*

"Zinc Sulphate, *2 ounces* (Imperial) or 60 grammes; Hard Soap, in shavings, *4 ounces* (Imp.) or 120 grammes; Distilled Water, boiling, Soft Paraffin, white, of each a *sufficient*

quantity. Dissolve the Zinc Sulphate in *four fluid ounces* (Imp. meas.) or one hundred and twenty cubic centimetres of the Distilled Water. Dissolve the Hard Soap in *forty fluid ounces* (Imp. meas.) or twelve hundred cubic centimetres of the Distilled Water. Mix the solutions; collect the precipitated zinc oleate; wash with hot Distilled Water until the washings afford little or no reaction for sulphate; dry on a water-bath and mix with an equal weight of the Soft Paraffin, melted; stir until cold." Br.

This ointment was radically changed in the Br. Ph. 1898 revision; instead of using zinc oleate made from oleic acid and zinc oxide, a process is ordered which directs the zinc oleate to be made by double decomposition between zinc sulphate and sodium oleo-stearate (hard soap). The product is a white, fine precipitate; it is, however, not a pure oleate, but a zinc oleo-stearate or oleo-palmitate. See *Unguentum Zinci Stearatis*.

This preparation has therapeutic properties similar to those of the ointment of zinc oxide, but is a little more stimulating. It is especially useful in *chronic eczema* and similar *cutaneous eruptions*.

UNGUENTUM ZINCI OXIDI. U. S., Br.

ointment of zinc oxide [Zinc Ointment]

(un-guën'tüm zin'ci ôx'î-dî)

Unguentum Zinci, Br., Ointment of Zinc; *Unguentum de Nihilo Albo*; *Pommade d'Oxyde de Zinc*, *Cérat épulotique, Fr.*; *Unguentum Zinci, P. G.*; *Zinksalbe, G.*

* "Zinc Oxide, in very fine powder, *two hundred grammes* [or 7 ounces av., 24 grains]; Benzoinated Lard, *eight hundred grammes* [or 28 ounces av., 96 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Rub the Zinc Oxide, which must be free from gritty particles, with an equal weight of the melted Benzoinated Lard, and with this incorporate the remainder of the Benzoinated Lard, previously melted; if necessary, strain the Ointment while warm, and stir thoroughly until it congeals." U. S.

"Zinc Oxide, finely sifted, 3 ounces (Imperial) or 75 grammes; Benzoated Lard, 17 ounces (Imp.) or 425 grammes. Add the Zinc Oxide gradually to the Benzoated Lard, previously melted at a low temperature; stir the mixture constantly until cold." Br.

The British ointment is weaker in the proportion of zinc oxide than that of the U. S. Pharmacopœia, the former containing about 15 per cent., the latter 20 per cent. *Commercial* zinc oxide should not be used, as it is usually gritty, and it is difficult to make a smooth ointment with it; the many expedients that have been suggested by various writers, such as the use of a paint mill or of a flat iron, or trituration with oil or with glycerin, are unnecessary if official or Hubbuck's zinc oxide is employed

and the directions of the Pharmacopœia followed. Cerate of zinc carbonate is no longer official.¹

This ointment is employed as a mild astringent application in *chronic ophthalmia* with a relaxed state of the vessels, in *cutaneous eruptions*, and in *sore nipples* and other cases of *excoriation* or *ulceration*. It has taken the place of the discarded *unguentum tutiæ*, or *tutty ointment*, prepared from tutty, or impure zinc oxide, by mixing it with five parts of simple ointment.

UNGUENTUM ZINCI STEARATIS. U. S.

ointment of zinc stearate

(un-guën'tüm zin'ci stê-ar'âtis)

Pommade de Stéarate de Zinc, Fr.; *Zinkstearatsalbe, G.*

* "Zinc Stearate, in fine powder, *fifty grammes* [or 1 ounce av., 334 grains]; White Petrolatum, *fifty grammes* [or 1 ounce av., 334 grains], to make *one hundred grammes* [or 3 ounces av., 120 grains]. To the White Petrolatum, melted on a water-bath, add the Zinc Stearate. Continue the heat until the mixture becomes smooth, then stir while cooling, until it congeals." U. S.

This ointment, introduced for the first time into the U. S. P. (8th Rev.), is very similar to the *Unguentum Zinci Oleatis* of the British Pharmacopœia (see p. 1318). It is used for the same purposes as is *Ointment of Zinc Oxide*.

UVA URSI. U. S. (Br.)

UVA URSI [Bearberry]

(û'vâ ūr'sî)

"The dried leaves of *Arctostaphylos Uva-ursi* (Linné) Sprengel (Fam. *Ericaceæ*)." U. S. "The dried leaves of *Arctostaphylos Uva-ursi*, Spreng." Br.

Uvæ Ursi Folia, Br.; Burren Myrtle, Mountain Box, Rock-berry, Kinnikinnick; *Uva-ursi*, *Busserole*, *Raisin d'Ours, Fr. Cod.*; *Folia Uvæ Ursi, P. G.*; *Bärentraube*, *Bärentraubenblätter, G.*; *Uva Ursina, It.*; *Gayuba, Sp.*

Arctostaphylos Uva-ursi, Sprengel, *Syst. ii.* (1825) 287; Carson, *Illust. of Med. Bot.*, i. 61,

¹ *Ceratum Zinci Carbonatis*. U. S. 1870. *Cerate of Carbonate of Zinc*.—"Take of Precipitated Carbonate of Zinc *two troyounces*; Ointment of Lard *ten troyounces*. Mix them." U. S. 1870. This preparation is an imitation of the cerate recommended by Turner, and is intended as a substitute for the former *Ceratum Zinci Carbonatis* and the still more ancient *Ceratum Calaminæ* of the U. S. Pharmacopœia, as being more reliable, in consequence of the frequent falsification of calamine. It is mildly astringent, and is used in *excoriations* and superficial *ulcerations* produced by the chafing of the skin, irritating secretions, burns, or other causes.

Ceratum Calaminæ. U. S. 1850. *Turner's Cerate*. The following is the old official process: "Take of Prepared Calamine, Yellow Wax, each, *three ounces*; Lard a pound. Melt the Lard and Wax together, and when on cooling they begin to thicken, add the Calamine, and stir the mixture constantly until cool." U. S. 1850. The uses of this cerate are the same as those mentioned above.

pl. 52; B. & T. 163.—*Arbutus Uva-ursi*, L., *Sp. Pl.* (1753) 395.—The *uva ursi*, or bearberry, is a low evergreen shrub, with trailing stems, the young branches of which rise obliquely upward for a few inches. The leaves are scattered, upon short petioles, from half an inch to an inch long, obovate, or oblong-spatulate, acute at the base, obtuse at the apex, entire, with a rounded margin, thick, coriaceous, smooth, shining, deep green on their upper surface, paler and covered with a net-work of veins beneath; furnished especially near the margin or near the midrib with minute hairs, which are usually abundant in young leaves, but may be few or absent in old leaves, especially those which have been much handled. The flowers, which stand on short reflexed peduncles, are in small clusters at the ends of the branches. The calyx is small, five-parted, reddish, and persistent. The corolla is ovate or urceolate, reddish white, or white with a red lip, transparent at the base, contracted at the mouth, and divided at the margin into five short reflexed segments. The stamens are ten, with short filaments and bifid anthers; the ovary round, with a style longer than the stamens, and a simple stigma. The fruit is a small, round, depressed, smooth, glossy red berry, with an insipid mealy pulp and five cohering seeds.
